AGRICULTURAL COLLEGE

TO OUR READERS.

What we should have said to you for this—the forty-fifth—time must ever remain among the things unknown, if the International Exhibition had not brought to London, and so inevitably to our office, that spade's-a-spade-calling woman, Miss Penelope Pomeroy. There's her chair, just as she has left it, appropriately all a-twist, and the hum of this really Cornish Bee is still upon our ears. She *is* a bee, because though she stings with a will, she also affords honey—she subscribes regularly, pays promptly, praises us when absent, and sends us Pine Apples. "So you have turned reformers, I see. If people choose to pay a guinea a-pound for Strawberries, why not let 'em? You will not be the better for having them supplied for half that money. Remember, Lord Melbourne was a reformer, and his reforming taught him a lesson. Whenever a change was proposed he always said, 'Can't we leave that alone?' So I say, Can't you leave the Covent Garden monopolists alone?"

With becoming dignity, and in a tone and words well expressing, we replied that we felt it our editorial duty to be guardians of the public interests.

"Guardians of public fiddlesticks! Pooh! If you are bent upon needful reforms, reform your own pages. You begin to need new type; you ought to report more country shows—I mean horticultural, not cock-a-doodle shows, we have enough of them."

We looked at each other—that is, we two Editors did, and the least young, with apparent humility, and certainly with great command of temper, said that both those reforms were contemplated, adding, with his usual ingenuity, "We shall not inquire, like Lord Melbourne, Can't we leave that alone?"

"That's right," said Miss Penelope, rising, "and if I were a man I'd give each of you a Cornish hug," which, as she is fifty and not well-favoured, we looked as if contented to have been spared.

We thought she was gone when the least old of us had closed the door, but it re-opened, and the comment reached us—"You've some rational new contributors. I am well pleased with them." No response could be given, and was not wished for, for the door was reclosed promptly and sharply. We looked at each other as men look when they feel inclined to be indignant, and yet think it best to seem indifferent. "Never mind," said the least young, "we will tell our readers."

INDEX.

Aberdeen Poultry Show, 73, 93
Abronia umbellata, 221
Abutilon, culture, 90; striatum sowing, 163; venosum culture, 187
Accrington Poultry Show, 360
Achimenes culture, 426
Æchmea fulgens for table decoration, 418
Agave ixtlioides, 260
Almond planting, 54
Alocasia culture, 72, 242
"Alpine Plants," 201, 288
Amaryllis, list and culture, 92; Rayneri, 145, 201
Amateur, who is an? 260; defined, 445
Amateurs beware, 103
America, jottings in, 288
American blight, 446
American wild flowers, 402
Androsace carnea *v.* eximia, 426
Annuals, for border, 108, 168; for flower beds, 261; for greenhouse, 204; for early sowing, 108
Anthurium Scherzerianum, 403
Ants, 367, 403; banishing, 187; in Cucumber bed, 344, in house, 242; puzzling, 261; on lawn, 327
Appleby's fumigater, 279
Apples—preservation of, 285; stock propagation, 169; trees, rabbits attacking, 124, budding, 445, mildewed, 373; leaves withering, 358; Crofton-Reich, Galloway Pippin, 236
Apricot, leaves curling, 309; trees gumming, branches dying off, 373, 374
Araucaria imbricata at Bicton, 435
Arbor-Vitæ hedge cutting, 260
Arboricultural Society's Transactions, 387
Argemone mexicana, 305
Artisan, who is one? 408
Arum maculatum, 285
Arundo donax, 221
Aristolochia Duchartrei, 29
Ash, grafting weeping, 261
Asparagus—beetle, 404; Connover's, 408; culture, 292, 428; cutting, 389; forcing, 32, 48; weak, 308, 326, 327
Aspect for glass structures, 148
Asphalte walks, 93, 260
Astera, growing for exhibition, 374; perennial, 279
Asystasia violacea, 29, 200
Aucubas, 54, 278; berries, 13; berried, 326; from berries, 168; for conservatory, 326; grafting, 344; sowing, 13
Auriculas, 286; stage, 440
Australian seeds, 127
Azaleas, after flowering, 341; thripa on, 278; weak, 13; white, 147; Fanny Tillery and Acme, 272

Bailnon Bird Show, 189
Banks, raised, in kitchen garden, 71
Bantams, 390, 410; cock's weight, 298; feather-legged, 40; Black cock's tail, 113; with Dorkings, 450; Game, 40, 428; breeding Game, 60; breeding Sebright, 172
Baptisia leucophœa, 352
Barkeria spectabilis culture, 147
Barrow Poultry Show, 94
Bath and West of England Poultry Show, 392
Bedding-out, 888
Bedding plants, a few fine, 272; failing in frame, 205; discordant opinions on, 238; house for wintering, 373
Bedlington Poultry Show, 411
Bees—apiary, largest American, 248; apiary extensive, 282; Association, Americae, 298; cheese boxes for, 172; in a chimney; 432; coal tar for house, 40, 95; empty white comb, 156; for cottagers, 329, 345, 431, 467; dead in combs, 248, deserting hive, 362; dirt from, 362; drones on Lady-day, 266; dying, 60, 396; dysentery, 96; eggs, are all of one sex? 468; Egyptian, 323; fighting, 266; foul brood, 19, 77, 113; gas tar on roofing, 95; hermaphrodite, 247, 314, 861; hives, cleaning, 60; new depriving, 156; hinges of bar-and-frame, 467; without a queen, 378; size of, 297; Stewarton, 265; for super honey, 114; ventilation, 265; unicomb, 154; Woodbury, 226, 414; hive-breakers, frustrating, 192; honey days, first, 361; disqualifying candied, 378; honey spurious, 18; Irish-keeper's difficulties, 449; keeping, &c., 362; dead larvæ ejected, 396; Ligurians, 40; propagation of, 394; management, 132; messing a hive, 414; manner and customs, 345; perishing in winter, 377; Mr. Pettigrew's balance-sheet, 247; price, 192; prosperity, 156; poison medicinal, 296; queenless hive, 416; queens, death of, 182; introducing, 431; piping 467; leaving hives, 467; regicide, 171; stocks examining, 131; superstitions, 207; during snow, 95; supers putting on, 336; in winter, 396; swarms artificial, 252, 362, 395; escaping, 414; early, 346, 361; loss of 346; transferring, 132; uniting, 414; wintering, 18; winter ventilation, 191, 225, 246, 261; near Wolverhampton, 170; production of fertile workers, 467; not working, 362; "The Honey Bee," 171
Beet as a bedder, 339
Begonias, crinita, 272; decaying, 186; winter-flowering, 41; with small flowers, 92
Beleperone ciliata, 200
Berberry planting, 54
Beta braziliensis culture, 261
Bignonia jasminoides not flowering, 242
Birmingham Columbarian Show, 74, 189
Birmingham Rose Show, 285
Blackberry orchard, 28
Blackcaps, rearing, 432
Boggy soil, cover plants for, 167
Boilers, 221; setting a conical, 109
Bombyx Neustria, 257
Bones, for chickens, 40; dissolving, 148; utilising, 358
Borecoles, 53
Botanic Gardens, 100
Botanic (Royal) Society's Show, 212, 271, 382, 420
Botany, lectures on, 386
Bottle-brush Plant culture, 224
Bottom heat on a large scale, 23
Bouquets, 204; hand, 215; Princess Louise's wedding, 232
Box, cuttings for edgings, 186; hedge straggling, 93; trees, transplanting, 369
Brahmas—chickens crooked-breasted, 20; cup for Light, 34, 72; crop diseased, 40; cockerel vulture-hocked, 60; prize cup for Light, 93; laying intermitted, 114; back featherless, Dark or Light, judging, 155; hens featherless, 208; cock, 248; tails, 298; and Dorkings crossed, 282; out of condition, 346; breeding, chickens cramped, hen dying suddenly, 330; not laying, 362; hen, separating from her chickens, 378
Bran for poultry, 172, 192, 226
Brecon Poultry Show, 57
Bristol Poultry Show, 16, 34, 78
Brittany, seaweed and market gardening of, 853
Broccoli, lifting in autumn, 287; culture, 451; varieties, 434; what is? 415, 434; for winter, 228; Cattell's Eclipse, 398
Broom culture in Madeira, 305
Buckwheat culture, 187
Budding fruit trees, 464
Bulbs, from the Cape, 389; management, 126
Bullfinch cage, 298
Bustard, 246; in Wilts, 153
Butterflies, Cabbage, 289

Cabbage Butterfly, 386
Cabbages, forwarding, 125; introduction, 66; planting, 167; wintering, 106
Cactaceæ, 68
Cactus culture, 90
Caladiums, culture, 204; soil for, 221
Calceolarias—bed, edging for yellow, 261; bedding in 1870, 44; for bedding, 149, 168; culture, 178, 213; culture and failures, 81; compost for, 373; cuttings, 428; failures, 137; flowering late, 209; herbaceous, 428; planting, 147; sowing shrubby, 92; weevils on, 409
Camellias—buds falling, 34, 127; culture, 67, 133, 158; cuttings, 294; not flowering, 148; after flowering, 242, 341; flowering in cold pits, 445; leaves blotched, 13; leaves spotted, 204; in cold pits, 294; repotting, 308; old, 34; sickly, 34; sl ot, 293
Camphor for fowls, 226
Canaries—silver cups for, 77; prize cups for, 93; not singing, 156; management, 156; scurfy-headed, 156; skin irritated, 156, 192; conservatory for, 156; silver cups at the Crystal Palace, 113; Mules at the Crystal Palace, 190; room, notes from my, 207, 225, 245, 265, 313, 383; spring moulting, 226; judging at Woodbridge, 264, 281; pip in, 298; eggs unfertile, 314; avoiding parasites, 346; mice in cage, 362; two hens to one cock, picking themselves, 432; at Stroud, 412, 448; become blind, 396; Bullfinch Mule, 192
Canary-fancier's wife's remonstrance, 246
Canna culture, 108
Cannell's boiler, 274
Carbolate of lime, 346
Carbolic acid *v.* vermin, 15
Carnations, in a bed, 205; culture, 363; sowing, 326; Perpetual or Tree, 863
Carter's prizes, 85, 87; Root Show, 402
Cauliflowers, 324; buttoning, 464
Caution, 346
Ceanothus azureus as a climber, 100
Cedar, a large, 288; transplanting, 221
Celery culture, 91, 219, 227
Centaurea candidissima, propagation, 167; sowing, 54
Cerena giganteus, 68
Chaffinches in garden, 342
Chamærops Fortunei in a Wardian case, 409
Cheilanthes elegans culture, 342
Cheimatobia brumata, 50
Cherries, summer-pruning, 408
Chichester, Mrs., 411
Chickens, dead in the shell, 192, 208, 396; distinguishing, 208; dying, 450; two sorts in one egg, 281, 362; partially hatched, 361; marking, 346; rearing, 344, 398, 359, 375, 410; voracious and giddy, 378
Chiswick Garden, 162; of Royal Horticultural Society, 386
Chitteprats, 248
Chlorocodon Whitei, 272

11	W		41.5	30.1	35.8	22	5 8	12 4	32 9	40 10	20	8 7	11

From observations taken near London during forty-three years, the average day temperature of the week is 41.4°, and its night temperature 29.5°. The greatest heat was 54°, on the 7th, 1845, and 9th, 1852; and the lowest cold 6°, on the 7th and 8th, 1861. The greatest fall of rain was 1.00 inch.

NEW YEAR'S HOPES.

A. H. KENT—whether Mr., or Mrs. or Miss I know not—you are responsible for my sitting down to write another New Year's paper, your kind words in the last number but one beckoned me to my chair, hade me get out the accustomed paper, and dip my pen into the ink, your genial expressions having warmed my heart; I therefore summon up memory, and write yet again, as there may be other A. H. Kents who dislike not a ketching pen, and who care, now and then at least, for omething in addition to business details. I have put for itle the words "New Year's Hopes;" and never were men nore in need of hope than now. "Hope springs eternal in he human breast," and well that it does. A poet of our entury picturing a time (so like the present),

> "When murder bares her arm, and rampant war
> Yokes the red dragons of her fiery car:"

Vhen all seem to forsake, when peace and mercy are anished, he adds—

> "Yet Hope the charmer lingers still behind."

o at the beginning of this year, in spite of the sad past, et us indulge in Hope—hope for more peaceful days, hope nat the New Year may not see, as the old one did, the abours of the husbandman, the Vine-dresser, and horti- ilturist trodden beneath the spoiling foot of the soldier.

The greater number of our readers and writers delight i a garden; a great, perhaps the greater proportion, are rofessionally engaged in horticulture. Amid their dis- ouragements, and all callings have many, yet gardeners ave many things which, borne in grateful recollection, e suited to comfort them, and make them content. hey are for the most part removed from the corrupting fluences of large towns; the wages are more likely to be isbanded carefully, books to be studied, and the minds of oung men better trained and disciplined, and the winter's enings better employed. Are they young married men ith families? A cottage in a garden, with garden and ral surroundings, is an innocent atmosphere in which to ing up children—healthier and purer for mind and soul. is a blessed thing to be able to rear our young ones vay from vicious scenes, and with the teachings of Nature fore their eyes. I have known where a country-spent yhood has been a great means of preserving a pure man- od. Well said Lord Derby at the last dinner of the rdeners' Royal Benevolent Institution—"A man might lk through a picture gallery, and see a great picture or ıtue, and yet it would only create within him a feeling admiration. But take the dullest lout out of the streets, the most savage Arab that ever slept under a dry arch, t him amongst flowers and trees, these will do him good, they are things which appeal to something in man that akens within him a consciousness of his duty to his eator."

Further, working gardeners with large families will soon ve a chance for their children which they had not so readily before—I mean the advantages of a State-watched-over and therefore an efficient education. This will in future years give boys a great advantage—grant to all boys the opportunity of an equally good education; subtract from their number the idle, the dull, and perhaps the sickly: then the remainder will have a capital opportunity of "going to the front," and doing well in the world. In Scotland, a country up to the present time far before us as regards elementary (not higher) education, this has often been seen. The father of Robert Burns was a gardener; he sent his son to school at six years of age, it was all his good father could do for him, but what a result! Had the parents of Burns, for I must include the mother's influence as well, been content to let their boy wander about without learning of any kind, one great name would have been blotted out of the roll of British literature. Therefore many parents with large families may take comfort, for if they send and keep their children to school they may have sons, aye and daughters too, known in the future; for "to the front" will go in years to come the educated, the clever, and the industrious.

But with the thought of the increased brain-work in England comes also the thought of the increased need of wholesome recreation. England is further and further receding from the "merrie England" of olden time, which meant to a great degree holiday-making—May-pole dancing, Christmas and Twelfth-night romping, and keeping all the many holidays of the old calendar. Now it is working England, and he who provides a wholesome recreation for his fellows in this brain-exhausting age is a public benefactor. But nothing gives such a change and benefit to men, to those, especially "in populous cities pent," as a glimpse of Nature. A recent writer in the *Saturday Review* says well—"In the way of recreation one view of Hampstead Heath is worth whole volumes of tropical travel; and a linnet in a Surrey hedge gives a fresher idea of Nature's charms than all the stuffed specimens in the zoological department of the British Museum." But no object to pursue daily and constantly equals horticulture for providing wholesome recreation, and, let me add, for promoting good temper. Wonderfully fascinating is it. Deny a garden; yet he who loves one will not be beaten. Thus we all remember "Picciola, or the Prison Flower," and he who watched it with intense delight as it unfolded itself from its first pair of leaves to its full flowering. Then there is Dickens's story of the boy, crippled and bed-ridden, who was devoted to his plant in the broken jug in the window; yes, and what comfort it gave him.

It is wholly wrong to ridicule one who has found some hobby, though we may not care for it. I have read of a very hardworking clergyman whose delight was to see and measure large trees. Every spare hour he could get away he was looking for a large tree; he had trees on the brain. He dreamed of trees of vast girth and height. His yearly holiday was devoted to searching for large trees. In a happy time of longer leisure he crossed the Atlantic, sailed up the mighty Amazon, and sought and found vaster trees than before. He collected pictures of trees, books on trees, facts about trees, and I should fancy drew from trees, as

well he might, many an illustration in his sermons. Was that a man to be laughed at? Certainly not. He had found a delightful, health-giving hobby; how much better was he situated than the multitudes of travellers who, aimless and yawning, pass through Europe with Murray in their hand. Oh! blessings upon every hobby that takes a man face to face with Nature. I like to hear an artisan grow eloquent over the beauties of his pets, be they fowls, or pigeons, or canaries. I like to see the entomologist start off with his net for the country.

"See to the shady grove he wings his way,
And feels in hope the rapture of the day;
Eager he looks: and soon to glad his eyes,
From the sweet bow'rs by Nature formed, arise
Bright troops of virgin moths and butterflies."

But to have full enjoyment you must take care and pains; as one of our writers well said in regard to poultry as a hobby, "to be fond of poultry is not merely to keep cocks and hens, but to multiply surface, to overcome difficulties, to supply that which is wanting, to concentrate (this is the point) on a cock and five hens the interest enjoyed by those who have thousands of acres and hundreds of fowls." Perhaps viewed in this light is the special value of florists' flowers—flowers which I humbly think are now too much neglected; but what happiness do they give! The man with an atom of backyard yet has a fund of enjoyment in it because of his Auricula stand, or his two dozen or so pots of Carnations or Picotees. One of my boyhood's friends was a tailor, a careful, comfortably-off man, who sought not his happiness at the public house, but in his little town garden, where he found room for prize Carnations and Gooseberries, fancy pigeons and bees.

Then there is the time which will come, or has come to us, the time—

"When life's day draws near the gloamin."

When as Crabbe's middle-aged hero said—

"I rode or walked as I had done before,
But now the bounding spirit was no more.
I showed my stranger guest those hills sublime,
But said, 'The view is poor, we need not climb.'
For home I felt a more decided taste,
And must have all things in my order placed;
In fact, I felt a langnor stealing on:
The active arm, the agile hand were gone.
I loved my trees in order to dispose;
I numbered Peaches, looked how Stocks arose."

And had Crabbe lived in these days, he might, perhaps, have added something of this sort—

"For quiet pleasures I began to seek,
Kept fancy pigeons, learned to play bézique."

A garden and home-bound pleasures have, we know, special charms for the retired and middle-aged man, and a happy thing it is when he takes to them.

One caution or two as to hobbies. Always bear in mind that people have various tastes, and do not cram your own special hobby down everybody else's throat. Then do not follow your hobby in order to stifle serious thoughts, nor love your pets better than your fellow Christians. All must be loved in order: the Creator first, then our fellow men, then the lesser, because soul-less, works of His creation. We should also cultivate a useful mode of applying observation. Bearing upon this, Addison in "The Spectator" (Does any body read it now in these sensation-novel days?) says, "My friend Sir Roger is very often merry with me upon my passing so much of my time among his poultry." The Spectator was spending a month with the worthy knight at his country seat in Worcestershire, who complained, "that his ducks and geese had more of his guest's company than himself." Addison replied, "I am infinitely delighted with those speculations of Nature which are to be made in a country life, and as my reading has lain very much among books of natural history, I cannot fail to recollect upon these occasions the several remarks which I have met with in authors, and to compare them with what falls under my observation." Now, this Journal does much in leading minds to the gardens, and to nature generally, and to the poultry yard especially, and so contributes, I believe, not a little to wholesome recreation. Among all longings none are so strong as the town man's longings for the country. "I long," said a Londoner to me, "to lie on a summer day on my back on the grass and look up into a tree." Even where the whole day is not spent in a town, yet if the day's occupation be in-doors the same feeling for bringing nature, or a reminder of nature near, is not unfrequently seen. The shoemaker and the tailor, and others of like in-door occupation are, and always have been, among the most ardent bird-fanciers; the goldfinch in his cage bringing the Furze common and the healthy glow there found, before the man's eyes and feelings, shut up though he be in a hot workshop.

I had an instance to the point brought before me this last spring. I was spending the day in one of the most lovely spots in this county, amidst scenery bordering upon the bold and romantic. I had walked through the wild wood that covered a hill top, from either side of which was a noble view. Then descending, I wandered along the margin of a most meandering trout stream that glittered in a more than spring sunshine. It was one of those rare and superb spring days, occurring rarely, when the weather is summer anticipated.

"The young lambs were bleating in the meadows,
The young birds were chirping in their nests;
The young fawns were playing with the shadows;
The young flowers were blowing toward the west."

Still I wandered on in the bright sunlight by the glittering stream, when I came upon an old, very old, paper mill, with its heaps upon heaps of rag bundles outside, the whole one blotch on fair nature, a proof how man's nastiness can mar God's beautiful earth. I almost cursed the thing for being there by the bright stream and the wild, yet, being the west of England, well-clothed landscape. Loathing I entered the old mill, and was soon among the dirt-coloured machinery, inside the dust-coloured mouldy walls, coarse shed-like walls, where all day long the wheels were droning and turning. Pinch-faced men in paper caps, old weasel-like withered men, were moving slowly here and there. Young men were there too, and women, and girls. Coarse paper in all stages of manufacture, from pulp to parcels ready for sale, was around me. All, wheels, budding, living creatures, all, exactly like a scene in the heart of a manufacturing town, and I could not believe that outside, just outside the cobweb-covered windows was a lovely scene in all its spring beauty. I sickened at the sight, when turning I saw on a rude partition of unpainted and worm-eaten boards a picture, a good engraving, of a Rose, with some pretty lines beneath it. How dearly must the one who placed that picture there have loved flowers; gathered flowers would soon have died in such an atmosphere. It was only a picture flower that would last. The picture cheered my eyes, and seemed to say there was something better in the world than rags, and pulp, and coarse mercantile paper; and though the wheels kept on droning and turning, and dinning my ears with their metallic noise, yet the Rose, and thoughts connected with it, in a measure atoned for all. We are told that Dickens had always before his eyes in his study at Gadshill vases of flowers, and that he never worked happily unless in their presence. Flowers may be regarded so variously. They call up reading and memory in regard to them, as one says—"It is always pleasant, walking in a garden, to remember the native home of the flowers, and imagine them surrounded by their own scenery. It gives them a new interest and a fresh beauty. We see them growing; the dewy Auriculas among the moss and snow of the Lower Alps; the Guernsey Lily in the Japanese meadow; the Ranunculus in the fields of Cyprus; the rich-dyed Pelargonium in the rank kloof of the Caffre frontier; the flaunting Dahlia in the plains of sunny Mexico; the burnished Eschscholtzia in the sands of golden California; the gay yellow bladders of the Calceolaria in the forests of Chili. Think of them with these surroundings, and you will see how the flowers fit their own special countries. A Caffre beauty would twist a thick cluster of dark crimson Pelargonium in her black oily hair. The dashing Mexican horseman, all leather and lace, would stick a huge white Dahlia in the band of his enormous sombrero. A Japanese lady would pace over the bamboo-bridge with a Guernsey Lily carried like a sceptre in her hand. Just so it is with vegetables; they, too, have their history, their legends, and their poetry. It is not uninteresting to recall whence they came, and how they reached in slow procession their great parliament house in Covent Garden. Crusaders, merchants, pilgrims, and monks brought them to us from eastern hill and southern plain, from northern meadow and from western forests."

But now let me turn to "our Journal," a great promoter, I know, of happiness in many homes, where its advent is looked for with pleasure, as said to me one constant reader of every one of its pages—"I look for it as I used to look for a love-letter from the post." I have met it this year in cottage, villa, and even in the precincts of a royal palace. Shows, I hope, will contain in future a more varied collection of birds, as did the Portsmouth Show, of which the report opened thus—"Combined with poultry and Pigeons the Committee offered for the

first time liberal prizes for cage birds and rabbits, and *thus* (mark the 'thus') secured the attendance of a very large body of visitors." The war in France has brought two things before us which it would be well to remember. First, we in England, depending so much upon France for eggs, may soon be suffering by still greater dearness of eggs. We ought to be able to supply eggs for our home consumption. Every cottager living by a roadside could cheaply keep fowls; landlords should be less jealous of their doing so, and neighbours less tiffy. Small farmers could add largely to their income by keeping more fowls; but for idleness and ignorance poultry would be kept in thousands where now only tens and hundreds are seen. Then the French war has taught all readers of newspapers the value of Carrier pigeons. If I ventured in general company to speak of the wonderful homing properties of the Antwerp I was smiled at, and heard the words "electric telegraph." Now it is all different. As in the siege of Constantinople A.D. 139, so in the siege of Paris A.D. 1870, the Carrier is the only safe telegraph. The electric wires in war are at once destroyed; if laid underground, as near Paris, they are found and dug up, or, worse for the besieged, "tapped," and their secrets known and revealed. Had the Parisians and French generally been as keen pigeon-fanciers as their neighbours in Belgium and Holland, there would not have been, as now, a scarcity in Paris of good and safe birds. Safe, for what hawk could catch a well-fed, well-trained Antwerp? I look, then, for poultry to be kept more generally, and homing Pigeons to be much more widely known. By the way, I would remark upon the great improvement in appearance of Antwerps as exhibition birds at the Crystal Palace Show. The three winning pens "of six working Antwerps in each," were beautiful in feather and matched well. If beauty and usefulness be combined I am sure they will be kept very generally.

I notice sometimes that odd questions are sent to our Editors. Now, to anticipate one and save them trouble. If any Pigeon-fancier is plagued with cats who make sad depredations on his birds, I will by all means recommend him for a sure and certain cure to get a dog of the following kind, that is——if he can. Mr. Pepys, in his Diary, saith, September 11th, 1661. "To Dr. Williams, who did carry me into his garden where he hath abundance of Grapes: and he did show me how a dog that he hath do kill all the cats that come thither to kill his pigeons and do afterwards bury them, and do it with so much care that they shall be quite covered; that if the tip of the tail hangs out, he will take up the cat again and dig the hole deeper, which is very strange; and he tells me that he do believe he hath killed above a hundred cats." That is the breed of dog for us Pigeon-fanciers to keep.

But 'tis time I should conclude. To some this is the only weekly periodical where there is a large family and careful parents, and "our Journal" forms, therefore, the chief evening reading. I know that a kindly article lights up into cheeriness many a quiet group, in a neat cottage, in a garden. A worthy Gloucestershire gardener, who being a Welshman, and whose name not being Jones—he bore of course one of the other two Welsh names—told me, warmly grasping my hand, he read all aloud to his wife. A good wife that, taking thorough interest in her husband's calling, as wives should.

My New Year's hopes are that this may be a happy new year. I hope the present war will cease and no other begin, and that the peaceful Eden-like labours of the garden will prosper. I hope there will be peace and plenty. I hope men will grow wiser, better, kinder, more loving, more brotherly and brother-like. Cultivate kindness—kind words, looks, and a kind present do wonders; it need be but a little one and of trifling value, but it warms the heart. One more word, and that a serious one. I have spoken of flowers being gathered from far-distant and different lands into our gardens; but there is another process of selection going on—the gathering of men into a better garden. May all who read these words be among those so selected, so gathered.—Wiltshire Rector, *Hilltop Rectory, Wilts, New Year's-eve*, 1870.

POTATO PLANTING.

On looking over the papers Mr. Lewis has written on this subject, I see he has not mentioned the way in which the Potato is planted in some parts (in Devonshire, for instance), as I suppose he wrote principally for amateurs and cottagers. I venture to add this plan, thinking it far supersedes those he noticed, although very similar to the one he mentioned for field planting. Should he not have said, The horses ought not to be worked abreast, or they will trample the Potatoes that are in the furrow, but that they should be worked one before the other? What an immense saving there is in this way to that of drilling out the ground first, and then carting the manure between the drills afterwards. One plough puts in one acre per day, and one man and a lad put in their quarter of an acre per day, and leave off at five o'clock. As, I believe this is not generally attended to, I will detail the simple way in which they do it.

Each allotment is half an acre, and we will suppose that the quarter of an acre of ground has been turned-up during the winter. The cottagers on the estates of the Earl of Devon, and I hope on all other estates, are allowed to keep their pig—the very life of an allotment—so that with a few bundles of ferns, long grass from hedges and ditches, and the straw from the quarter of an acre of Barley, which each cottager is bound to grow every year as per agreement, he thereby, with all his gleanings, manages to prepare from four to six good loads of manure. The ground is planted alternately with Barley and Potatoes. The manure is thrown in heaps in the middle of his Potato ground a day or two before planting; he has been busy for a night or two preparing the seed by cutting and making each sort ready for the eventful day; and whether he puts them in himself or hires, the work is begun early the next morning. There is one thing he will surely not forget—the few coppers, or maybe a bit of silver, he has hoarded up in some snug corner "vor a drap o' cider vor tatty planting." The dung is spread evenly over the ground first, the Potatoes are placed in convenient lots, and now the work begins in earnest.

The line is stretched across at the lower end of the ground; the man with his mattock digs out the furrow, the lad with his basket of seed Potatoes drops them about 10 inches apart; the line is then shifted 22 inches off. The lad, with a good-sized iron-toothed rake, next rakes in the dung on the Potatoes, the man follows him, making another furrow to cover it, and the end being gained, he wheels round and makes another furrow for the next row; the boy following, drops the seed as before. The row finished, and the line shifted, the boy rakes in the dung, the man following covers it with the next furrow, and so on to the end.

Thus it will be seen the man is always in his work, not having to walk a foot without tending to diminish his day's work, and this, too, without leaving a footmark behind him, and the soil is laid on the Potatoes in the lightest possible manner. The Potatoes all in, the paths are shovelled up, and all is left until the Potatoes are beginning to make their appearance, when a rough rake is run over the whole to knock down clods and to kill all seedling weeds. All hoeing and earthing-up is done during the mornings and evenings by the cottager and his family, the allotment being within a few minutes' walk of the village.

It often happens that the cottager is short of garden room at home, and then he will drop a few Broad Beans in every three or four rows at planting-time, or scatter a pinch of Turnip seed after they are earthed-up, which seems not to interfere with the Potatoes. It is a pleasing sight to walk through these allotments on a fine evening, and see the many little happy groups at work with an earnestness that ought to shame the man spending his last farthing in the tap-room, or the landowner who says, "I could not think of taking away a field from my farmers to lay out in allotments." The noble landlord and his late worthily-esteemed lady, whom I have named, have given prizes every year for the cleanest and best-kept allotment, and for the best piece of Barley, Potatoes, and Mangold Wurtzel, &c. The competition is very spirited, and produces the best results.—J. Taylor, *Maesgwynne, South Wales.*

DWARF POINSETTIA PULCHERRIMA.

Mr. Fish in his "Doings of the Last Week," December 22nd, says—"The Poinsettia can never look compact so as to have a fine head of crimson floral leaves." As I read those lines I had a plant on the table before me, which I measured; it stood 5½ inches high from the pot, a 4-inch one, and the floral bract measured exactly 8 inches across. I then measured another in the conservatory, in a 6-inch pot, which had two floral bracts, one was 4 inches high and 7 inches across, the other 5 inches high and about 8½ inches across. These were taken off the old plants and struck after July 1st, though I do not exactly remember the date, and were merely joints with eyes, as I cut the long shoots I took off the old plants into

three or four cuttings according to the size, and I find the joints of the older wood make better plants than the points. They have been growing without any check in a very light house with plenty of moisture, and all that struck have flowered, and all, except one that pushed two eyes, are in 4-inch pots.

I intend to try experiments next summer by taking cuttings at different intervals, and pinching-back the earlier-struck ones, as I think if they are not overpotted, but kept growing in plenty of light, and with moisture enough so as not to let them lose any leaves, they may be kept very dwarf. The old plants (two in number), from which I took the cuttings, both pushed fresh blooming shoots, but were too tall and straggling to be ornamental. I do not pretend that the floral bracts of young plants treated in this way, are so fine as those on strong unchecked shoots on old plants, but they are more ornamental, and occupy but little space.—C. P. Peach.

SELECTIONS OF GRAPES.—No. 1.

Probably there is nothing so perplexing to the amateur and practical horticulturist as choosing from the numerous kinds of fruit trees named in catalogues those best suited to his requirements. All the varieties enumerated may be really first-rate for some particular want of the horticulturist, each may supply some need, or answer a particular purpose, but though it may suit one person, it may not suit another, because the means are different. One may have an unheated house, and the other's house may not only be heated, but have the border inside, and not unfrequently it is furnished with chambers for hot-water pipes, so that the soil can have artificial warmth as well as the atmosphere. So varied, indeed, are the means or conditions of culture, that instead of looking at the long lists of varieties in bewilderment, I have learned to esteem them. Our nurserymen are not slow in bringing into notice any new and good varieties of fruits; they cling to old and justly valued kinds of proved excellence; at the same time they are not long in expunging from their lists what the popular voice says is superseded by other and better kinds, as regards quality, size, and productiveness. Judging from your correspondents' column, some of your readers experience a difficulty when they have erected a vinery in regard to what kinds they should plant, in order that, with the means they have provided and can afford, it shall give them in due season Grapes in perfection. On the varied conditions under which Grapes are grown in this country, I purpose at this time to make a few remarks, and my doing so will, I hope, elicit from others their experience.

Out-door Grapes.—History informs us that Vines were planted on more than one southern slope of this country, and Grapes grown which if not such as might be taken from the Vine and eaten, were good for making wine. Though I am no believer in the value of wine of whatever brand as a beverage, or for any purpose, though it may be of value medicinally, yet there are many at the present time who would, were it practicable, grow, as did our ancestors, Grapes for making wine. "Upwards and Onwards" has proved that some little distance north-west of London—namely, at Woodstock, in Oxfordshire, with the aid of walls, Grapes can be grown of a quality suitable for making wine little if at all inferior to many foreign vintages. There can, therefore, be no doubt as to the possibility of growing out of doors in this country, by the aid of a wall or other means, Grapes suitable for wine-making; but it remains, as far as I know, to be proved whether they can be grown in any part of the kingdom without some artificial aid beyond culture on southern slopes. I am in hopes that such may prove the fact; but so far as I have experience it must be in some warm spots in the far south, and there only.

So far north as here (Yorkshire) Grapes from Vines against walls with south aspects, are when at their ripest so sharp in flavour that few can partake of them, but I have seen Grapes ripened against walls both in the north and west that could not be devoid of sugar, or the wasps would not have devoured them so greedily, and I have no doubt they would have made very good wine. Indeed, for eating they did not compare unfavourably with imported Grapes. From want of thinning, however, they were small in berry, and the shoots not being stopped sufficiently, nor due regard paid to the laterals so as to concentrate as much as possible the energies of the Vines on the bunches of fruit, these did not ripen so well as they otherwise might have done. Another disadvantage of Vines out of doors is their often being planted in soil wholly unsuitable—heavy or wet—so that they are late in starting into growth, and do not ripen the long sappy shoots which are produced in great profusion. Under favourable conditions of soil, a light and dry one, and against sunny warm walls, especially the walls of houses with projecting roofs, they may be grown to a considerable degree of perfection. I have known them grown successfully on the south wall of a cottage at Weston, in Shropshire, and also as far north as Acomb, York. The finest Grapes I have seen grown out of doors were at Oxton Hall, Tadcaster, by the aid of a flued wall, about twenty years ago; and at Parlington, Bryam Hall, and other places, good examples of out-door Grape-growing might at one time have been seen; but of late years glass has been so cheap that this mode of Grape culture has been neglected.

A selection of Grapes for out-door culture is as follows:—Royal Muscadine, round berries, and rather large; this kind, as far as I have experience, is the best of all, ripening with the greatest certainty and perfection. Early White Malvasia; the berries are much smaller than the Royal Muscadine, and the Vine a great bearer. Early Malingre, round or slightly oval berries, small; it is a great bearer. White Romain, berries oval, small; great bearer. Grove End Sweetwater, berries round, medium-sized; good bearer. These are all white or amber-coloured when ripe. Of black or purple sorts, Black Cluster, berries roundish oblong, and small, and so the bunches also are. It is, however, the best of all for out of doors. Cambridge Botanic Garden, berries oval, rather large; bunches short; a great bearer. These two are the best black Grapes for walls. Ingram's Prolific Muscat, berries oval, small. Espiran (Esperione), berries large, roundish; abundant bearer, and hardy, but not so hardy as the two first-named black kinds. These are all the kinds I advise for growing by the aid of walls, and those who can afford to cover the wall with glass would be acting wisely and well to do so, the kinds named being well-suited for a glass-covered wall in a cold climate, where by such an aid they may succeed as well as or better than they do against an open wall in a more favourable climate.

Vines in Unheated Houses.—The houses may be of three kinds—viz., 1, Ground vineries; 2, Orchard houses; 3, Lean-to houses, or a wall with a south aspect covered with glass.

1. *Ground Vineries.*—Of these I have not sufficient experience to warrant my giving a selection. I have no doubt of succeeding with them, but I have grave doubts of some kinds flourishing as they do in a house with a larger amount of enclosed air. Perhaps some of your correspondents will favour us with their experience, naming the kinds most suitable for ground vineries.

2. *Orchard Houses.*—I am equally at fault with this kind of house as with ground vineries. By an orchard house I mean a house constructed of wood and glass, and detached from walls or other buildings. Of it, as regards Grape culture, I have no experience. By reporting progress those who have experience in this mode of culture would confer a benefit on myself and others.

3. *Lean-to Houses against Walls or Buildings with a South or South-west Aspect.*—Narrow houses sufficient only for a path answer well, but there is no disputing the fact that large houses are the best; 18 to 20 feet I consider quite wide enough. I have seen and grown very good Grapes in houses but 12 feet wide. The chief considerations to be taken into account for the successful ripening of Grapes in cold houses are—1. To have the border considerably above the surrounding level, one half its depth above it under any circumstances, and entirely when the situation is low, and water inclined to lodge. 2. To concrete the bottom of the border, both inside and outside, with the needful incline for water to run to a point whence it can be carried off by a drain. 3. To have as much of the border inside as possible, though part outside is not bad, but, on the contrary, I believe beneficial. 4. To drain the border well. 5. To make the border of fresh and not very rich compost, open, and not likely to settle into a close soapy mass. 6. To have front and top ventilation to effect by air-giving a thorough change of air, as well as to prevent damp. 7. To husband the sun's heat by early air-giving, and shutting-up whilst the sun has considerable power, always leaving on a little air to prevent the scorching of the leaves. 8. To employ no more wood in the construction of the house than is absolutely needed for stability, having the squares of glass of good size, and not being too sparing as regards its weight; 21-oz. glass is the lowest weight that ought to be used; 26-oz. and even 32-oz. will not be too heavy. Avoid the best quality of glass; 3rds will be quite good enough. Lastly. If a span-roofed house be employed have it wide, not less than 20 feet, and have the sides wood and glass, the light coming to within a

foot of the border. Narrow span-roofed houses I have found neither so warm nor even-temperatured as those which are larger.

A selection of Grapes for houses such as those above referred to may consist of the following:—Black Champion, berries roundish oval, good bunches; earlier than the Black Hamburgh. Trentham Black, berries oval, large; good bearer. Black Hamburgh, berries oval, bunches and berries large. Frankenthal (Pope's or Victoria Hamburgh), berries roundish oval, large; undoubtedly the most useful Grape in cultivation. The above are all Black Grapes of first-class excellence. Of the white or amber-coloured kinds I would recommend Buckland Sweetwater, berries round, large; a great bearer. Foster's White Seedling, berries roundish oval, of good size; this must supersede the Royal Muscadine. Chasselas Vibert, berries round, large. General della Marmora, berries round, large; a good bearer. Sarbelle Frontignan, berries round, small, but a good early free-bearing kind with the full Frontignan flavour. The foregoing are all first-class Grapes, having large berries and bunches, except the last, which is given to meet the taste of those requiring the Muscat flavour. White Frontignan I have found ripen fairly in a cold house, but to do so fully it requires a good heat, and then it is a first-rate Grape.—G. Abbey.

THE GLADIOLI OF THE PAST SEASON.

Of these there were thirty-two, divided into various sections according to their price. The first class comprised Armide, La Candeur, Orphée, Pericles, Robert Fortune, and Rosa Bonheur; the second Agathe, Delicatissima, Elizabeth, Horace, and Sylphide; the third Adanson, Bijou, De Humboldt, Rosea Perfecta, and Sultane; the fourth Lacépède, Livingstone, and Rubis; and the fifth Angèle, Anna, Canova, Cleopatra, Donna Maria, Elegans, Hortense, Irma, Laure, Marthe, Picturata, Regina, and Spectabilis. As these are all seedlings of M. Souchet, it will at once strike anyone acquainted with what raising new varieties is, and the difficulty of obtaining good varieties, that the number is a great deal too many: and so in truth we have found. There are some even in the first class which will not long remain in select collections, while in the fifth class there is probably not one that will be grown. They are all more or less pretty, but do not fulfil the requirements of those who regard quality and excellence of flower and spike as amongst the first requirements. It is ever thus with raisers. Nor are they alone to blame. The craving of the public for novelties is such that they will devour anything; and hence raisers are tempted to select from their seedlings flowers that they would have otherwise consigned to the rubbish heap, or, as in the case of the Gladiolus, thrown into mixtures. The following judgment on them is the result of observations on my own bulbs, supplemented with, in a few instances, notes taken at the Royal Horticultural Society's Special Show, and the Metropolitan Florists' Society's Show at the Crystal Palace.

Armide.—Large and good-shaped flowers; of good habit. The substance of the petals is such that it remains some time in bloom. Colour, white tinged with rose, and flamed and blotched with bright crimson. It seems to be an early-flowering variety like Shakespere; at least my bulbs of it had flowered out before August 15th.

La Candeur.—I cannot understand why this should have been placed in the first series; as a white it is inferior to Madame Desportes, while the petals are pointed and the spike by no means good.

Orphée.—This I regard as about the best variety of the year. It has a long noble-looking spike, a blush white ground strongly flamed with bright carmine, and is altogether a very fine flower. A capital constitution, and prolific in spawning.

Pericles.—This bloomed very late with me. It is another of the light rosy ground flowers, margined and striped with rosy purple, with pure white blotches. My impression of it is that it will not hold its ground.

Robert Fortune.—A very long spike; cerise, largely margined and blotched with dark crimson, violet throat. The petals have a line of pure white in their centre. A very fine flower.

Rosa Bonheur.—Very long spike; the flowers large, white; fine large purple blotches. The top petal has the habit of lapping over backwards, which somewhat detracts from its merits; but I believe, with all that, that it will make a valuable variety.

Agathe.—Large flowers, and a good spike flamed with rose and yellowish blotches, carmine margin. This, too, I believe to be a good variety, although some have dissented from my view of it.

Delicatissima.—I was greatly pleased with this flower. It is of a peculiar shade of colour—white, slightly suffused with lilac, while the lower petals are white. A very distinct sort.

Elizabeth.—Long spike; large flowers, deep rose, strongly flamed with purple; large purple-carmine blotches with white stripes. A fine variety, and at times very brilliant.

Horace.—A good scarlet, with white lines in the centre of each petal; brilliant in colour, and I think likely to be valuable.

Sylphide.—White ground, slightly flamed with carmine. Although the spike is good the petals are pointed, and I do not think it can be regarded as a good exhibition variety.

Adanson.—Large and well-opened flower of a peculiar colour, somewhat in the style of Anais, and very desirable for the contrast of colour. It would do well for the front row of an exhibition stand.

Bijou did not bloom with me (cerise orange), but I heard it but poorly spoken of by those who had bloomed it.

De Humboldt.—Large, bright carmine, flamed and margined with carmine; crimson blotches on white ground.

Rosea Perfecta.—A very pretty variety, rose tinted with violet; all the petals with a white line in them.

Sultane.—Bright rose purple blotches, not first-rate.

Lacépède.—I did not bloom this, but Mr. Kelway (no mean judge) thinks well of it. Rosy violet, and striped with lilac.

Livingstone.—Small, but exceedingly pretty; bright violet cerise with a sort of metallic reflection. Very good for the first row of a bed.

Rubis.—Long spike and large flower, blotched carmine on a white ground. All the petals with a white line.

Of the other flowers I know nothing, but I fancy from the estimate placed on them as to price that I have no great loss. It will thus be seen that I regard Orphée as the premier flower of the season; that I have a good opinion of Robert Fortune, Rosa Bonheur, Armide, Agathe, Delicatissima, Horace, and Rosea Perfecta. My estimate may be wrong, but I question if it will be very far out. Our hopes of getting the new Gladiolusea of 1870 are becoming fainter every day. Oh! what a terrible comment on the message of "peace and goodwill" is that cruel devastating war.—D., *Deal.*

ORCHIDS FOR A CONSERVATORY.

I shall be very much obliged by your stating the names of a few Orchids that could be successfully grown in pots in a conservatory, where the temperature ranges from 46° to 55° day and night. I have now only one Orchid, Dendrobium nobile, which last year flowered beautifully, and I should be very glad to add a few others that a similar treatment would suit.—Sigma.

[The following would succeed in your conservatory:—Cypripadium insigne, Odontoglossum grande, Odontoglossum Alexandræ, Lycaste Skinneri, Lycaste Harrisoniæ, Epidendrum vitellinum, Zygopetalum Mackayi, Oncidium bifolium, Lælia majalis, Lælia albida, Barkeria Skinneri, and Barkeria spectabilis.]

FRUIT TREES FOR THE NORTH.

The result of my continued experience in fruit-growing in these parts may be interesting and of importance to those of your readers who contemplate planting new and improved varieties of fruit trees. It is a very fatal mistake to be guided entirely by "descriptive catalogues" of fruit trees which refer only to the climate of the south of England; but those subscribers who reside in the north of England, or in Scotland, may presume that varieties which succeed in this latitude will also prove successful with them. It is not uncommon to find a gardener occupying his attention and a valuable space on his garden wall in an abortive attempt to grow Chaumontel Pears, or some other variety of fruit equally unsuited to the climate; and it is to guard against such a tantalising proceeding, as well as to encourage the growth of the many new hardy and delicious varieties of fruit that have lately been brought into cultivation, that I venture to record the result of my experience. Some of the finest fruits ripen in great perfection with us. You must excuse me reminding you that for Marie Louise and nine other varieties of dessert Pears, my predecessor in this garden was, at Chiswick, awarded a Banksian medal.

About twenty-five years ago there were upwards of ninety

varieties of Pears in this collection. These have been gradually reduced, by removing those not well adapted to the climate, to nearly one-third of that number, even while including some of the best varieties lately added. By a careful selection of these for each season an abundant dessert may be procured for almost the whole year round. I shall, therefore, for the benefit of amateurs or the uninitiated, give the seasons at which each variety is fit for use in the following list.

For gardens that are not too dry for dwarf or Quince-rooted Pear trees, and for Apples on the Paradise stock, I would recommend these; they occupy half the space, come immediately into bearing, and the fruit will be larger and earlier than on trees of a different description.

LIST OF FRUIT TREES ADAPTED FOR CULTURE AT ELGIN.

PEARS FOR THE WALL.

Doyenné d'Eté, or } July and
Citron des Carmes } August.
Jargonelle. August and September.
Summer Beurré d'Aremberg. Oct.
Sinclair. October.
Beurré Superfin. Begin. of Nov.
Marie Louise. November.
Doyenné du Comice. December.
Hacon's Incomparable. December.
Winter Nelis. January.
Joséphine de Malines. February.
Easter Beurré. March.
Bergamotte Esperen. March.
Beurré de Rance. April.
Fortunée. May and June.

PEARS FOR STANDARDS.

Doyenné d'Eté. August.
Williams's Bon Chrétien. Sept.
Beurré d'Amanlis Panaché. Oct.
Autumn Bergamot. October.
Beurré Superfin. November.
Aston Town. November.
Muirfowl's Egg. November.
Beurré d'Aremberg. Dec. and Jan.
Forelle. January.
Doyenné Defais. January.
Beurré de Rance. March.
Beurré Giffard. September.

PLUMS FOR THE WALL.

Rivers's Early Favourite. July.
Bryanston Gage. August.
Reine Claude de Bavay. Sept.
Coe's Golden Drop. October.
Blue Impératrice. October.
Jefferson. September.

PLUMS FOR STANDARDS.

Belgian Purple.
Dennistou's Superb.
Lawson's Golden Gage.

The following also succeed:—

Van Mons Léon le Clerc.
Thompson's.
Brown Beurré.
Beurré Bosc.
Passe Colmar.

The following dessert Apples have lately come into bearing, on Paradise stocks, and have been much appreciated:—

DESSERT APPLES ON PARADISE STOCKS.

Irish Peach. August.
Kerry Pippin. September.
Margil. October.
Pitmaston Pine Apple. October.
Cox's Orange Pippin. November.
Blenheim Orange. Nov. and Dec.
Sam Young. December.
Ribston Pippin. January.
Melon Apple. January.
Screveton Golden Pippin. Feb.
Duke of Devonshire. March.
Lodgemore Nonpareil. April.
Reinette du Canada. May.
Allen's Everlasting. June.

All sorts of large kitchen Apples bear abundantly.—J. McCulloch, *Gardener, Duffus, near Elgin, N.B.*

P.S.—For the present I withhold any report upon Peaches, Apricots, Nectarines, or Cherries, all of which we grow successfully.

[You will oblige us by sending your other notes. We covet all records of the results of practice.—Eds.]

EARLY-FLOWERING PERSIAN CYCLAMEN SEEDLINGS.

As you have invited your readers to detail their mode of growing the Persian Cyclamen so as to flower early, I have been induced to give my experience relative thereto. Having procured a packet of seed early in the spring of the present year, and having made up in readiness a hotbed of fermenting materials, I sowed the seed on March 8th, and kept the young plants growing in their seed pan until the middle of April, when I had them potted off singly in thumb pots. I plunged them in the same frame as before, and towards the end of May I gave them a shift into 4-inch pots. The compost I used in potting was a mixture of peat soil, a little loam, leaf mould, and cow dung. They were forthwith taken to the stove, placed on a shelf near the glass, and always kept pretty moist, being well watered about once a-week with weak liquid manure made from pigeon dung. They grew remarkably fast—so much so, that from their size I thought I would require to give them a larger shift; however, I did not do this, thinking that they would flower earlier if left in the same pots than they were likely to do had they been shifted. To my delight and astonishment I observed the first flowers showing in the first week of September, and they came generally into flower by the end of October.—Hugh Rose, *The Gardens, Grangemuir.*

I sowed a packet of Cyclamen persicum seed on March 3rd, 1870, and some of the earlier plants bloomed in October. I have now corms about 2 inches in diameter with many flowers fully out, and with from twenty to thirty more buds to come out. Of course these are the most forward and best amongst the seedlings. The seeds were sown in pans in a forcing pit. I pricked out the seedlings as soon as they had two leaves, and constantly repotted them, some being now in 36-pots. As soon as the heat seemed to draw them they were moved into a cooler place, and some have been put back for a week or so into the forcing pit to bring on the flowers. I cannot quite decide whether the corms do best covered with soil or entirely raised above it.

The seedlings had no special soil, excepting a good allowance of silver sand and plenty of drainage. The great point is that they have never been forgotten for a day. Some of my corms showed bloom when very small.—A Lady Amateur.

Although we have not plants like Mr. Clarke's "fit for exhibition," we have a few dozen plants in 5-inch pots, many of them in bloom, and all showing abundance of flower buds, from seed sown at the beginning of last March. The corms are from 1 to 1½ inch in diameter, each supporting erect about thirty finely variegated leaves varying from 2 to 4 inches across.

The seed was sown during the first week of March in small seed pans, well drained, and filled to within an inch of the top with a mixture of loam and leaf mould, with a little silver sand; the soil patted down to keep the seed at the desired depth, and watered through a fine rose; then the seeds were sown as quickly as possible, and finally covered with about an eighth of an inch of silver sand. If sowing is performed quickly the moisture will penetrate through the sand and render another watering (which is very liable to wash the seed bare) unnecessary.

The pans were then placed in the stove with a pane of glass over them, and a piece of white paper laid loosely over the glass for shading. They were frequently examined, and when found dry were gently dipped in the tank, so that sufficient water should flow over the rim to moisten the whole surface.

The glass was gradually raised as the seedlings touched it, and when they had formed two leaves they were carefully pricked off 3 inches apart in boxes drained and filled with the following compost—dried cow dung two parts, leaf mould one part, turfy loam one part, and a little silver sand. The cow dung is collected from a pasture after it has been well baked in the sun. It is a good plan after it has been sifted to water it with boiling water, which kills a great number of vermin liable to be injurious to the plants. The loam is used quite dry, and rubbed through a half-inch sieve.

The boxes were next placed in a low span-roofed house, where Camellias and other plants were making their growth. The young plants were allowed to remain in the boxes for about two months, when they were lifted with balls and lightly potted in 60-sized pots, with the same compost, which I may here mention is used with good results for all our Cyclamens. They were then plunged in bottom heat in the same house, and repotted, as the roots reached the sides of the pots, in 4-inch, and finally in 5-inch pots, always returning them to their quarters in the bottom heat as quickly as possible.—J. Braithwaite, *The Gardens, Verulam.*

PRIZES FOR TENDER PLANTS.

We have a village show, a very healthy baby two years old, and growing fast; we want to offer £10 for six stove plants, open to the world if we can get any competition. Our idea is to have an annual £10 prize—viz., £5, £3, and £2 for first, second, and third prizes for a varying article. This year we say six stove plants; but some suggested it should be for stove and greenhouse, others think that the six should be stove only, not mixed with greenhouse plants—they might come in their turn in future years. How say you?

Is the £10 better divided into three prizes or given all in one? We have three good growers near here, but we must induce strangers to compete. How can we best do so?—C. E. Ellison, *Bracebridge, Lincoln.*

[It is quite certain that you will do wisely to divide the £10 into three prizes as you propose, and we recommend them to be offered for "Six stove and greenhouse plants. N.B.—Either six stove or six greenhouse plants, or a combination, not more than six altogether, of stove and greenhouse plants, may be exhibited in this class."—Eds.]

Intense Cold.—It may be interesting to some to know how we fare at Prestwich with the frost. Commencing with Decem-

her 20th, the thermometer registered 8° of frost; 21st, 10°; 22nd, 20°; 23rd, 24°; 24th, 28°; 25th, 26°; 26th, 18°; 27th, 18°; 28th, 14°; 29th, 12°; 30th, 17°; 31st, 25°. The readings are taken from a registering thermometer every morning at 8 o'clock. It faces the north, and is 4 feet above the ground. The rime is truly splendid, especially on the Pinuses, Araucarias, and Holly. The Rhododendrons and Aucubas look very drooping. —Stephen Castle, *Bent Hill Gardens, Prestwich, Manchester.*

GROUND LEVELLING AND PRACTICAL GARDEN PLOTTING.—No. 10.

DRAWING PLANS.

Fig. 33 consists of eight hexagonal beds, and is drawn and transferred to the ground in the following manner:—Draw parallelogram A B C D and the diameter lines E F and G H. Draw lines 1 2 and 3 4, being half the distance between A H and H E. Where line 1 2 crosses line E F is centre *a*; from centre *a*, with radius *a i*, draw circle *i*. Where line 3 4 crosses line E F is centre *b*; from centre *b* draw a circle with the same radius as *a i*. Find the distance from centre o (the point is where the two diameter lines cut each other) to centres *a* and *b*, mark the same distance on each side of centre o on line G H, as points *c* and *d*, and with the same radius as *a i* draw a circle from centres *c* and *d*. With *c* and *d* as centres find points *f g* and *e h*, which is done in the following manner: — With radius *c a* draw an arc as in *f* on line 1 2; where the arc cuts line 1 2 is centre *f*, as shown: also draw an arc as in *g* on line 3 4; where the arcs cut the line is centre *g*; with radius *d a* find centres *e* and *h* in the same manner, then draw the circles with the same radius as *a i*. Apply the radius six times to the circumference, as chord *r s*, and it will form the hexagon.

To trace it on the ground, the base line A B is 41 feet 4 inches long. Insert stakes in points A and B; from B to C is 62 feet; insert a stake at point C. With A and C as centres find point D, and there insert a stake. Lay lines joining points A B, B C, C D, D A, then lay the diameter lines E F and G H, inserting a stake at each point. Find half the distance between stakes A and H, and insert a peg as at point 1. Find half the distance between stakes H and B, and insert a peg as at point 3; find the corresponding points on line C D, as points 2 and 4. Lay lines joining pegs 1 2 and 3 4; where line 1 2 crosses line E F insert a peg as at centre *a*. With a string 6 feet long trace circle *i*, as shown by radius *a i*; where line 3 4 crosses line E F insert a peg, as at centre *b*. From the peg at centre *b*, with the same length of string as *a i*, trace a circle from peg *b*. From centre *o* measure 10 feet 4 inches on the diameter line towards G, and insert a peg as at centre c. Centres *a* and *c* are equal distances from centre o. From centre *c* trace the circle with the same radius as *a i*, with *c* as centre. With radius *c a* or *c b* trace an arc cutting line 1 2, as shown in *f*, also trace an arc cutting line 3 4, as shown in *g*; where the arcs cut the lines are centres *f* and *g*. Insert a peg at each point, and with the same radius as *a i* trace the circles. Centres *e*, *d*, and *h* are found in the same manner.

To form the hexagon inside the circle, apply radius *a i* six times to the circumference, as shown in *r s*; insert a peg at each point, as at points *r s*. When the six sides are found lay a line from peg to peg and cut out the beds. Proceed in the same manner with the other beds until the design is complete.—M. O'Donnell, *Gardener to E. Leeming, Esq., Spring Grove, Richmond.*

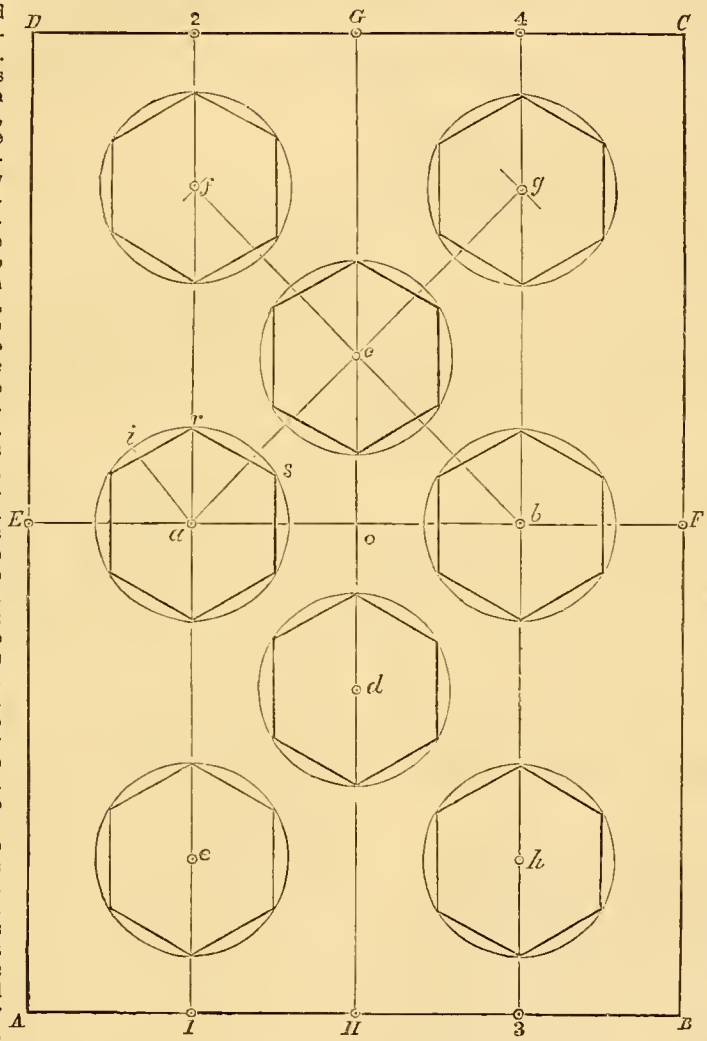

Fig. 33. Scale 12 feet to the inch.

CHRYSANTHEMUM CULTURE.

I can assure Mr. H. Benham (see vol. xix., page 472), I have no wish to mislead him, nor anyone, in my notes on Chrysanthemums; and when I said, Give no manure water till the buds are formed, I merely gave my mode of treatment for the last three years. I am perfectly aware I differ on this, as on several other subjects, from many practical gardeners, still as long as I confine my remarks to what my own practice has taught me, no harm can be done.

Reverting to the subject of liquid manure for the Chrysanthemum, I say pot the plants in good rich compost, withholding manure water till the flower buds are well set, then give it in moderation. I might possibly be tempted to use it earlier had I not the material suitable for their growth. My own opinion of manure water is, that it has a tendency to create an undue circulation of the sap, thus causing the plants to make more wood than is necessary, and not giving any addition in size to the flowers, whilst by giving it as I do when the buds need additional stimulus, it improves them very much. I am perfectly aware that this is quite at variance with the practice of most good growers, but having tried theirs under various circumstances, I prefer my own system. Plunging is and may be very well for those who have not the time nor means to attend properly to the watering, for, as I said before, nothing suffers more than the Chrysanthemum from being short of water. I consider it better to be without them if you neglect them once. I am perfectly aware of the extra water they

require, but where there is a regular system of watering, and one man for his own work, no evil results can accrue to them owing to their not being plunged. In my own case I prefer my plants not to be plunged, as less skill is then required to water them. Plunged plants have this disadvantage, that they require far greater attention in watering. I have seen plants which have died simply through overwatering. Of course, a keen practical man can tell at a glance the plants which require watering, but to an inexperienced hand the difficulty is great. The Chrysanthemum is naturally a gross feeder and likes plenty of water, still it is possible to overdo the watering. I this year had an argument with a gentleman respecting plunging plants out of doors, and the gist of my argument was, that I considered the water that passed from the plants, especially if manure water is given, had a tendency to become sour, and unless the bed or whatever they were plunged in was well drained, the plants would in a manner absorb their own refuse. My idea may be wrong, still it is so.

I have for three years given the bulk of my Chrysanthemums their last shift the first week in August, and, of course, I should not do so, it being as convenient for me to pot in July as August, if I found no benefit from it. The Pompons and a few early kinds are potted in the first or second week of July, but the plants I have now in flower were potted in August. I have a very distinct recollection, in the year 1864, I being then in Cheshire, of potting in the middle of August a few Chrysanthemums which had been overlooked at the early potting, and notwithstanding the prediction of the head gardener as to their failure, they proved the best of the season. A considerable amount of care and thought will be required as to what plants are best suited for late potting, so as not to overpot them; for my own part I would not repot a plant in August unless it was in good condition and likely to be benefited by the shift. In potting in the first week of August the roots should be at the sides of the pot at the end of the same month, thus leaving the whole of September and two weeks of October for the plants to make and perfect their flower buds.

I am open to conviction, and no one can read the Journal with more interest than I do, though I find much to differ from; and in writing these short notes and in all others, I give to the public a few of my practical observations, trusting they will be received in good faith, even though they do not coincide with the general statement of things.—Stephen Castle, *Bent-Hill Gardens, Prestwich.*

P.S.—Since writing the above I have been referred by a friend to an excellent article in the Journal of August 19th, 1869, written by Mr. R. Fleming, gardener to R. Houghton, Esq., Sandheys, Waterloo, Liverpool, in which, though his treatment differs from mine in many respects, still on the subject of manure water, he says that the time to apply liquid manure is when the plant shows the buds. In this, of course, I perfectly agree.

WAR ON FRENCH GARDENERS.

A letter which has been received by field post from a young German gardener with the army round Paris, dated 4th of December, will be read with interest. The letter runs as follows:—

"Alas, that I should have such sad things to tell you of the gardens! they are completely deserted, and all the fine collections are left to ruin. I speak especially of the establishment of Messrs. Croux, Durand, & Son, at Bagneux. Croux's establishment is occupied by the Bavarian artillery; in the large Palm house the horses are put, which eat the tall plants like fodder. The splendid Conifers (Wellingtonias, Picea Pinsapo, Deodar, &c.), which lately were there in large numbers in their greatest beauty, are ordered to be made into a hedge in order to block out the view from the batteries of the French forts.

"But still worse is the condition of Croux's establishment at Aulnay. In the Jardin pour études Pomologiques the splendid trained trees are quite destroyed from the breaking of the wires which supported them, and now about two thousand sheep and from eighty to a hundred cows are in the gardens, and of course eat up everything.

"Not less sad is it to see the state of the gardens of Durand fils, near Clamart. The greenhouses are mostly destroyed by the thick shower of bullets, and the plants in them withered or frozen. The day before yesterday these were exposed to —6° R. [18½° Fahr.], and yesterday covered with snow."

[The above extract from a German newspaper has been sent to us by a correspondent at Hamburg.]

New Violet.—A correspondent in Honolulu, after making a botanical tour in the Kaala range, says, "Botanising on this island is not without considerable danger. Only imagine descending a steep decline of 70°, which had to be done chiefly by swinging from the roots of one tree to the branches of the next one below, and that at a height of 2000 feet above the deep gorge beneath our feet." Nature, however, seems in all cases to provide a reward for her admirers who voluntarily expose themselves to such dangers for the purpose of bringing to the eye of science her numerous hidden beauties, for the writer continues to say, he was not a little surprised by the discovery of a Violet with splendid snow-white waxy flowers, some of which were almost half an inch in diameter, and exquisitely perfumed. He considers it probably a variety of Viola chamissoniana, which he found in its ordinary state lower down in the forest; but the pure white flowers stretching out their long peduncles above the surrounding low undergrowth, and luxuriating in the full sunshine of an azure blue sky, far exceed in beauty those of V. chamissoniana, which are of the ordinary violet colour.—(*Nature.*)

SLOW COMBUSTION, AND ECONOMY IN FUEL.

I observe in your Journal of October 27th, that "R. S." has succeeded in keeping up the heat of his greenhouse by having two holes drilled in the ashpit door. Will he kindly say is it the ashpit door he had the holes drilled in, or the fire door? because very few flues have doors to the fire as well as the ashpit. Would you state if it would not be better to have a regulator on the fire and ashpit door to regulate the fire, instead of the damper? as I fancy the damper prevents the heat rising. My boiler is a conical one with a jacket, and the fire, to go up the chimney, has to go through it, but it takes a great deal of fire and attention to keep the heat up. Can you give me any idea how large a fireplace should be to allow of sufficient coals being put on to burn and to keep up the heat during the night?—A. Y.

[We have no doubt that "R. S." in alluding to the holes made in the ashpit door, at page 321, does mean the ashpit door, and not the firebox, or furnace door. Perhaps "R. S." may have something to add to his interesting article. Meanwhile, we may say that where economy in fuel, and sufficient heat, and slow combustion are required, both the furnace door and ashpit door should be made to fit as closely as possible. Many of the best makers of these doors send out ashpit doors fitted with a valve or other moveable opening to regulate the draught, and this would avoid the expense of cutting out the hole and fixing the valve over it. We should not like to intrude an opinion into this domain of "R. S.," though we should incline to think that one hole in the centre, with the valve, would have been sufficient. When once a fire is lighted and burning freely, it is amazing how small a quantity of fresh air is necessary to support slow regular combustion. On this principle all our best iron stoves are made. The valve in the ashpit door can thus be screwed up, so as to leave not more air on than that alluded to by "R. S." It is by the ashpit opening that the combustion must be regulated. Many iron stoves have also a small valve opening above, and, therefore, over the firebox and fuel—not so much or at all for ensuring combustion, as to prevent smoke going up and choking the small iron chimney.

When you inquire whether it would not be well to have a regulator on the furnace as well as the ashpit door, to regulate the fire, instead of the damper, we must answer Yes, and No. Yes, so far as we have stated above, the ashpit regulator would regulate combustion, and that can be done to a nicety only as the result of watchful attention, and noting the state of the weather. Yes, too, so far as a very little air coming over the fuel would tend to lessen, and mostly consume the smoke. But, then, as to these rendering a damper unnecessary, when a small house is to be heated economically from a boiler, we say decidedly No. In heating by a flue, a brick stove, an iron stove, or an earthenware stove, in a house of any sort, there is no necessity for a damper. After the fire is fairly going, a little slit in the ashpit door will not only regulate combustion, but will concentrate the most of the heat in the flue or stove. But with boilers, and especially conical boilers such as yours, where the heat passes so quickly into the chimney, a damper is important for concentrating that heat round the boiler, instead of allowing it to go up the chimney so easily. If the damper is close-fitting, it should not go quite home, but a quarter of an inch or less would permit of slow combustion. We find this matter is simplified by having a close-fitting damper across the chimney, but with a hole an inch in diameter in the centre, so that there shall be a passage

for smoke and heated air, and yet a surface presented to throw back the greater amount of rising heat over the boiler.

There are here two things well worthy of attention. First, many of our readers who are new to such matters become confused in so much talk about slits in furnace doors and confining heat by dampers. This would be simplified if it were understood that a good heat must *first* be obtained before either regulating slit or damper can be used. In producing that heat there is no means for preventing waste of heat up the chimney at first. Thus, if we went to the furnace of "A. Y.," with the fire out, we would clean out the firebox, clinkers, &c., keeping the ashpit door shut, then we would clean out the ashpit, making for our own comfort as little dust as possible. In all that "R. S." says of a clean ashpit we thoroughly agree. Were this little matter better understood, we should not have young fellows coming in dire perplexity telling us that the fire would not draw, and no wonder, when the ashpit was stuffed up to the bars with ashes. Any old washerwoman would have shown more sense. Catch her suffocated with smoke because the ashpit was filled up!

On lighting the fire we would leave the ashpit door open to have a good draught, waste of heat notwithstanding, just as in lighting a fire in an iron stove we would leave the ashpit door partly open until we had a good fire. It would only be when we found the pipes from the boiler getting warm we would partly shut the furnace door; then when warm enough, shut it altogether, and merely admit a little air by a valve or otherwise, and shortly afterwards we would use the damper, as our object would be to continue the heat by slow combustion, and not to make it greater. It is possible by a careful use of the air at the ashpit door that the damper may be rendered as unnecessary in the case of a boiler, as in that of an iron or a brick stove, but according to our present impressions we should like to have the damper in addition.

We have frequently stated that for a small single house heating by hot water cannot but be expensive, as the waste is so much greater in proportion to the small space heated. Hence, for small detached greenhouses, heating by a flue either above or below the floor will always be more economical and require less trouble than hot water. In large houses, or a series of houses, the matter is different. The economy consists in the heat being pretty well absorbed *in a clean flue* before the heat reaches the chimney, and then because the material of the flue holds heat once given to it longer than water.

Our experience with stoves led us first to be thoroughly convinced of what we had previously acted upon—the small quantity of air sufficient to keep up a slow combustion and the necessary heat after that heat had first been obtained. Just bear in mind that the damper and ashpit valve become valuable only after heat has first been obtained.

Here we may add, that provided "A. Y." has a close-fitting ashpit door, he might have three or four holes drilled in the centre of it, each about one-eighth of an inch in diameter, before going to the expense of brass valves, and if he do so, will he kindly report the results? We shall be sure to find better data in such cases than from the furnaces of large places, as there it is so difficult to get little matters attended to—even valves are knocked to pieces with a stroke of a poker, or a barrowload of fuel is pitched over them, and there is nobody to bear the blame. Attentive amateurs will be our best help as respects economic heating.

The second matter to which we wish to allude is simply this, that a small boiler and as small a furnace as possible are by no means synonymous with economical heating. A gardener of large experience, who has taken to a small nursery, has lately told us the trouble he has had in heating a house with a small boiler, and the furnace so small that two or three spadesful of fuel fill it. Now, in such a case there must have been almost constant poking, and, of course, valves and dampers must have been at a discount. The boiler in this case was placed according to what we believe to be a too-general error; small as it was, it rested on the level of the firebars; the belief somehow having got about that the more the boiler formed the firebox, the greater would be the heat absorbed. Now, in several such cases as that referred to above, great advantage, and economy in fuel too, have been obtained by letting the little boiler remain as it was, and sinking the firebars beneath it to the depth of one or two firebricks; more firing could thus be used at a time, and when the heat necessary was obtained, the continuous heat could be easily regulated by the ashpit door and damper, without so frequently and wastefully poking the fire.

We think these simple matters more important than what "A. Y." further requires, "How large a fireplace should be to allow of sufficient coal being put on to burn, and to keep up heat during the night?" but we shall be glad if some reader will contribute to the object desired. For ourselves, long ago we made some experiments in this way, but we found that difference of fuel and difference in circumstances made such astounding differences in results, that we came to the conclusion that no rule thus obtained could ever take the place of careful watchful attention to individual cases. A furnace to consume such fuel as "R. S." uses, may be much smaller than a furnace to be supplied with ashes, cinders, breese, or the cheapest and best heat-giving fuel. A very small furnace, unless for a very small place, is generally a mistake every way, and by the poking, and punching, and frequent supplies required, consumes more fuel than if it had been larger. A similar error is constantly committed by those who have their little houses heated by hot water, which houses could only be safe in such severe weather as we now have, by heating the water nearly to the boiling point. It would be far more economical in the long run, and better in every way, to have a third more piping, and never have the water higher in temperature than from 160° to 180°. A first saving here is anything but ultimate economy.—R. F.]

NEW BOOK.

The "Field Quarterly Magazine and Review." Vol. I. London: H. Cox.

Four issues of this quarterly publication are now united in a well-bound volume. The contents are exclusively good selections from the *Field* weekly newspaper, and combine especially information relative to all our national sports and the country house.

LATE PEAS NORTHWARDS.

After two months' silence Mr. Porter now says I put Veitch's Perfection in the wrong place as a late Pea, which I emphatically deny; I say this as my own experience, which is more than Mr. Porter can say, for had he grown it and Ne Plus Ultra side-by-side, he would have proved the difference to be in favour of Veitch's Perfection. If this has any weight, I may say that I exhibited at the Prestwich Floral and Horticultural Show in August, 1870, a dish of Veitch's Perfection as well as Ne Plus Ultra, and the first prize was awarded to Veitch's Perfection, which also took the same honour in September at a local show held a short distance from here. Has any practical gardener (which Mr. Porter is not) accustomed to this part of Lancashire seen Peas late in November? Certainly neither Mr. Porter nor anyone has done so this year, though it is a pity he does not state the exact date (he says late in November), and if he saw Peas growing after the 20th of November. Between November 20th, and the same date of December, the frost at night varied from 3° to 9°.

Ne Plus Ultra is undoubtedly a first-class Pea, as I said at page 324, but I have yet to learn that it is better than Veitch's Perfection for late supply. I distinctly remembered that when I pulled up, at the end of October, the haulm of Veitch's Perfection, sown at the same date as Ne Plus Ultra—though Veitch's Perfection was a week later in coming in—Ne Plus Ultra was quite dry, while the other was quite green. Though, as I stated, I gathered the last dish on September 30th, it was by no means the last of the Peas, as I found them very useful for soups up to the end of October. I have no doubt what I gathered for soups would have made some families dishes, but I ceased gathering as soon as the cook said the peas boiled irregularly. I intend seeing whether it is possible to gather good peas, say, at the end of October and beginning of November. I have not seen any at that time good, but merely fit for soup, whether in Staffordshire, Cheshire, Derbyshire, or Lancashire.—Stephen Castle, *Bent Hill Gardens, Prestwich, Manchester.*

DARLINGTONIA CALIFORNICA.

Messrs. Veitch & Sons have grown this plant for a considerable time in their houses at Chelsea.

In London, as in California, this curious plant possesses the same irresistible attraction to insects, and as I have repeatedly examined living plants at Chelsea, perhaps the following notes may have some interest.

This so called Pitcher Plant, when fully grown, resembles in

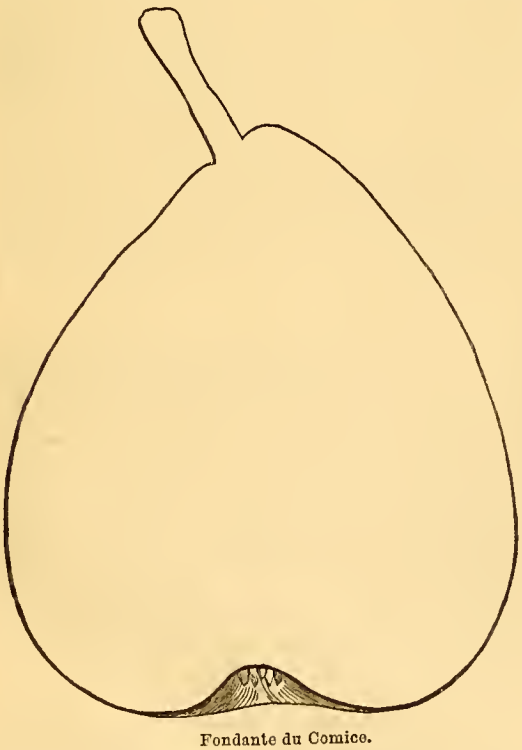
shape the upraised head and body of an excited cobra, with hood expanded and prepared for a spring; the head is at right angles with the hollow vertical body, and apparently presents no opening by which an insect could enter; under the place where the lower jaw would be, hang two large reddish appendages like the wattles of a fowl. At Chelsea this plant possesses such an extraordinary attraction for flies (principally blue-bottles), that the hollow "pitchers" are generally full of their dead bodies; what this attraction is I am unable to say, as the plant is scentless.

Last year I had a Darlingtonia before me for some three or four hours, whilst sketching it, and I then observed that the blow-flies made straight for it immediately they entered the room. Insects alight on the red wattles and then fly upwards into the (previously unseen) red-lipped entrance to the tube; owing to the sudden twist in the neck of the pitcher, they are at once compelled to descend the hollow body, and, as far as I have observed, they never return alive. They keep up a buzzing noise for half an hour or so, and then apparently die.

The old pitchers are generally full of dead flies, &c., and the lowermost insects, in rotting, cause the pitchers to decay and split, the flies within being then displayed. These dead flies often drop out through the fissures and become grouped round the bottom of the plant.—Worthington G. Smith.—(*Nature.*)

NOTABLE PEARS.

Fondante du Comice.—As a society there is none which has done more for the advancement of pomology than the "Comice Horticole of Angers." Like the Royal Horticultural Society of London, it is one of the few that enjoy the privilege of possessing a garden where horticultural experiments are conducted, and where pomology receives more than ordinary attention. The number of new varieties of fruit which have originated in that garden is sufficient evidence of this statement; and the mere fact that such Peare as Doyenné du Comice, Fondante du Comice, and Cassante du Comice, have originated there speaks highly in favour of the establishment.



Fondante du Comice.

Fondante du Comice, which we now introduce to our readers, first fruited in the Society's garden at Angers in the year 1849. It has been slow in coming into notice in this country, probably from the ignorance of cultivators of its merits. Six years ago we met with it in the collection of M. André Leroy, at Angers, to whose courtesy in furnishing us with numerous specimens of the new varieties of fruits raised in that city, we now acknowledge; and during the past season it has fruited in the garden of the Royal Horticultural Society at Chiswick. Having now ascertained to what extent this variety is adapted to our climate, and having found it worthy of notice, we take an early opportunity of making our readers acquainted with its merits. It is only when foreign varieties have been grown in this country that any confidence can be placed in their reputed characteristics.

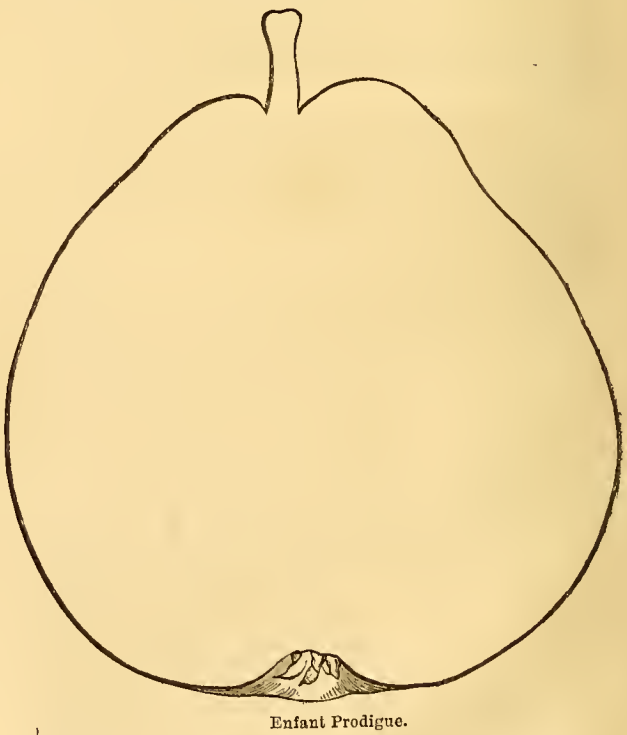
This variety is obovate in shape, even and regular in its outline, smaller and more symmetrical than when grown on the Continent, where it is rather uneven. Skin smooth, of a uniform yellowish or pea green, covered with distinct markings of russet and russet dots. Eye small and open, with erect acute segments, set in a very deep and smooth round basin. Stalk woody, also green like the skin, about an inch long, and inserted obliquely with a fleshy lip on one side of it. Flesh white, crisp, very juicy and sweet, slightly acidulous, and very refreshing, being in this respect somewhat similar to the old St. Germain.

Ripe in the end of October, and the beginning of November.

The tree is a good bearer, and not at all a strong grower. It succeeds best on the Pear stock, and as it makes rather an awkward pyramid, the bush form will be the most proper for it.

Enfant Prodigue (syn. *Rousselet Enfant Prodigue: Nectarine* of Leroy, erroneously).—This is one of numerous varieties raised by Van Mons, which keep cropping up periodically, as additional evidences of the indefatigable labours of the industrious Professor. It was raised about 1830 in his garden at Louvain, and although it is well known on the Continent, it has never been much cultivated in this country. It is not always of first-rate quality, but in situations such as the west of England, and other favoured localities, where it does succeed, its fine brisk sweet juice and high flavour commend it as a variety well worth growing.

The fruit is variable in size; the specimen here figured being larger than is usual. It is uneven and bossed in its outline. The skin is clear dark green, changing as it ripens to pale yellow, which is sometimes quite obscured with veins and



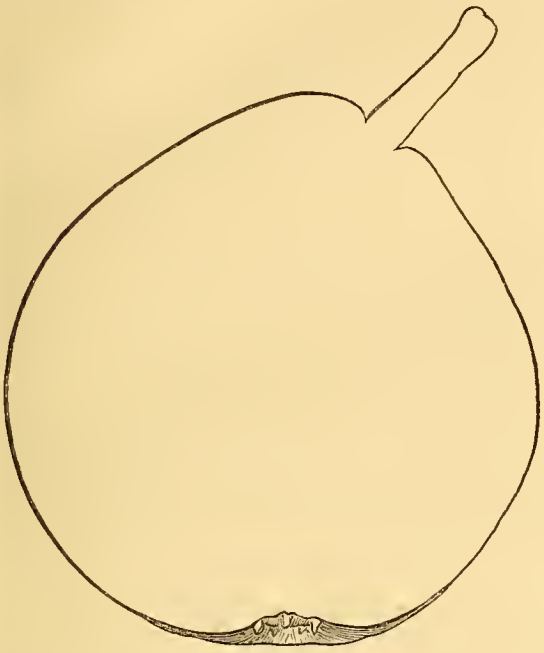
Enfant Prodigue.

mottles of cinnamon-coloured russet. Eye large and open, with broad, flat, leaf-like segments set in a rather deep and uneven basin. Stalk half an inch long, woody, set in a wide shallow depression. Flesh greenish under the skin, crisp, and half melting, very juicy, sweet, acidulous, and with a fine aroma partaking of that of the Seckle.

An excellent Pear, with a fine acidulous flavour, ripe in the beginning of October, and continuing in use throughout the month.

The tree is a good bearer, and forms a handsome pyramid.

Millot de Nancy.—We have here a posthumous variety of Van Mons', of which the earliest information we have is in 1843, when it was named by the son of the Professor in honour of M. Millot, of Nancy, an ardent pomologist. We have grown it for the last twenty years in this country, and proved it to be of the highest excellence. In some seasons, as for instance in 1866, it was somewhat astringent in flavour, but generally it has proved excellent.



Millot de Nancy.

The fruit is roundish, inclining to turbinate, even and handsome in its outline. The skin is smooth, of a uniform coppery red or warm cinnamon colour caused by a coating of russet over its whole surface, and dotted with ashen grey dots. Eye rather small and open, set almost level with the surface. Stalk about an inch long, woody, fleshy at the base, straight, and obliquely inserted in a very slight depression. Flesh whitish, half melting, very juicy and tender, rich, sweet, brisk, highly flavoured, and with a fine perfume.

It is a first-rate Pear, ripe in October, and during November.

WORK FOR THE WEEK.

KITCHEN GARDEN.

It is hoped that, in accordance with repeated injunctions, the wheeling of manure and trenching-up vacant quarters in this department have been regularly and systematically followed up in favourable weather. Let this kind of work be continued as often as opportunity offers. All green refuse and decayed matter when trenched-in should be strewed over with lime to hasten decomposition and destroy insects. Choose also the opportunity of dry frosty mornings to fork-up ground previously trenched, so as to get the surface in good working order; if severe weather continue but little can be advised in the way of cropping. If, however, a change take place and the ground can be worked, the first opportunity must be seized to make a second sowing of *Broad Beans* and *Peas* on a warm border. Sow a moderate breadth of Early Horn *Carrot* and Short-top *Radish*, to be sown in drills alternately, covering with healthy sandy soil, and protecting with any available matter. An excellent method of fastening down such material is to place long willow rods at convenient distances, pegging them down at each end with a strong hook. *Cauliflowers* under handlights require constant attention. Keep the surface stirred. An excellent plan to catch slugs among these is to split large Carrots and lay the pieces about the plants; by picking them off on mild mornings, an immense number of slugs may be taken.

FRUIT GARDEN.

Continue the pruning and nailing of the hardier kinds of fruit trees at every opportunity, have a good plank to stand upon, and if very cold wear also a large pair of wooden clogs. No considerate master will ever censure a man for being careful of his health. In pruning and nailing wall trees let them be entirely removed from the wall, which should be swept with a birch broom, if there is any fear of insects lodging in the crevices; the trees should then be renailed with fresh nails and shreds, using as few as possible, and of strength according to the size of the branches. The pruning of Currants and Gooseberries should be deferred for a time, as if sharp weather prevail during this and part of next month, birds are apt to be very destructive to the buds. Prune espalier Apple and Pear trees, and fork-up the ground about them in frosty weather to disturb and destroy insects. In the orchard thin out cross and crowded branches from Apples, Pears, and Quinces, it is a great mistake to leave too much wood. Scrape off moss and lichen from the stems, and if time will serve, dress both these and espalier trees with a mixture of quicklime and clay brought to the consistence of thick paint. If this be done well, there will be no need to scrape them for some years.

FLOWER GARDEN.

All is hard as adamant here; we can do little until the Snowdrops begin to peep up. Some kinds of ground work may be proceeded with, and the mattock or pick will be in request. Should the present severe weather continue, the chief operations will consist in giving additional protection, and in covering those plants which in ordinary seasons it is not necessary to protect. Roses must have additional coverings to the roots—such as litter, moss, leaves, or sawdust, and the tops must be protected with straw, hay, fern, or evergreen boughs—in fact, anything of the kind, and the drier the material used the better. The same remarks apply to climbers on walls; over these mats may also be fastened, for although coverings are not required to be firm, the mats are useful in keeping the other materials dry and clean. Auriculas will now begin to require some extra attention independently of keeping them perfectly clear of dead leaves, which must be removed very gently for fear of injuring the root or stock. They may in mild weather have an occasional watering, carefully guarding against any moisture remaining in the heart. Give all the air possible, taking care to cover the frames well at night. Look over the beds of Pinks and Pansies; plants which have but lately been removed are very liable to be raised by the frost; these must be carefully fastened by pressing the soil gently to them when it is tolerably dry. The soil which has been exposed to the action of the frost, may the first fine day be returned to the Ranunculus beds in order that they may settle down before planting. Carnations must be carefully gone over, those in beds fastened if loose, and cleared of dead leaves, which when lodged on the plants retain moisture which is injurious to them.

GREENHOUSE AND CONSERVATORY.

Keep the conservatory at a temperature of about 45° by night, raising it to 55° in the day, with plenty of air at every favourable opportunity. Keep the atmosphere moderately moist, as much for the preservation of the flowers as for the comfort of the visitors. Keep every part of the house as clean as possible. Remove flowers as soon as they become shabby, and endeavour to concentrate the floral beauty of the place in this one house. Stove plants will suffer no injury for a few days in the above temperature, but hardwooded greenhouse plants, as Heaths, should not remain more than a few days at a time in such a temperature. Take care that the Camellias do not suffer from want of water now they are blooming. Prune, train, and clean the climbers on the rafters, &c. The greenhouse in the generality of establishments is a mixed affair, where hardwooded and softwooded plants are obliged to be together. In such places a compromise must be made in the treatment by keeping it a few degrees warmer than Heaths and other Cape plants require, and yet sufficiently warm for Pelargoniums, Calceo-

larias, &c. Arrange the plants in groups, so that air can be admitted to the Heaths at times when it would be injudicious to admit it to softwooded plants. Admit air at all favourable opportunities, but be careful of north-east winds.

STOVE.

Now that the shortest day is past, some of the plants which it is intended to make the most of during the growing season may be started gently, preparatory to being potted, towards the end of this or the beginning of next month. Among these, such plants as Ixoras, Allamandas, and Dipladenias may be started. Do not increase the temperature much this month, except by taking advantage of sunny days, and then a syringeful of water may be drawn over the plants without any risk of doing injury. All the plants wanted for late blooming must be kept back for the present. If not done before, the whole of the Clerodendrons must be shaken out, their roots reduced, and repotted in small pots in light sandy-loam compost. Place them in heat until they have made shoots about an inch long, and then, unless required to bloom very early, they may be preserved for a time in a lower temperature. Luculia gratissima, as soon as it has done blooming, must have the side branches shortened-in a little, and be placed in heat to produce cuttings for propagation. As soon as the shoots are 2 inches long tie a tight ligature below the lowest joint, and when the bark has swelled a little, say in about a fortnight, the cuttings may be taken off, potted singly in very small pots, plunged in a gentle bottom heat, covered with a hand-glass, and they will strike very readily.

FORCING PIT.

Remove the plants to the conservatory as fast as the flowers expand, and introduce others from the reserve for succession, placing them first at the cool end of the house or pit, so as to excite them gradually. A few Pinks and Sweet Williams may be started, and plenty of Lily of the Valley, Sweet Briar, and other sweet-smelling plants. Gardenias must also be started, and as the Stephanotis is a great favourite with the ladies, a plant or two should be placed in the warmest end of the pit. Maintain a growing moist temperature of from 60° to 65° or 70° with sun heat.—W. KEANE.

DOINGS OF THE LAST WEEK.

ON New Year's-eve we have similar weather after a week of keen frost, as we had at Christmas-eve. Very fortunately the frost has been greatly counteracted as respects vegetables and Wheat fields by the frequent fall of snow, which will be of great protecting benefit to everything beneath it.

Our chief work out of doors (for ground work or moving earth was impossible) was wheeling the rubbish-heap and soil, and, on cutting a spinney, collecting flower *stakes* and Pea stakes, stakes for Hollyhocks, Dahlias, &c., in a rough state, so that we could finish them at home in unsettled weather. We prefer for flowers clean straight stakes with the bark on, to deal and lath sticks, however nicely whittled. The object of a stake is merely to support a plant, but the less the support is seen the better.

In most gardens the number of sticks required from one-eighth of an inch in diameter to 2 inches across is astonishing. Preferring those with bark on them as less conspicuous, it is always advisable to have a quantity laid up in store, and not be forced to try and find some at seasons of the year when going into a coppice for them might give offence, from disturbing young game, &c. A gardener now-a-days, to obtain what he wants, must keep his eyes about him. When such small sticks are pruned and straightened, it is well to put them into bundles, tied firmly, which keeps them in the desired position. Pea stakes can also be arranged in sizes, and pointed on bad days, when men could scarcely stand out. Collecting and bringing them home was good work for the frosty weather, as most of the snow has come on at night. Some time ago we made remarks on pointing sticks. For good-sized ones, three strokes of the bill are sufficient. For small flower sticks, two strokes of the knife are sufficient—the first slips off the half of the diameter at the base, the other takes away the half of what remains, leaving a neat point. We have seen more whittling over the point of a little stick than would have done for more than half a dozen of a similar size—a matter of importance where myriads of these are used.

In-doors, besides the general attention as alluded to last week, the chief work has been cleaning and picking over plants where they had any leaves not quite healthy, and attending to their various wants, giving as little water as could be to keep things right in such severe weather.

The following matters have also received, or should now demand attention :—

The orchard houses, on cutting the last Grapes, the roofs being covered with snow, were again well smoked by burning partly broken and bruised laurel leaves. This was done generally by way of precaution, as it could do no harm, and few insects can stand the pungent smoke, quite as obnoxious to some insects as the smoke of tobacco, whilst it costs nothing but getting the laurel leaves and young shoots. The roofs being rather open, it would of little use smoking the houses unless they were covered with snow.

Some Pear trees that had a little scale on the branches we meant to have syringed with water during this keen weather, so as *to surround the branches with a layer of ice*, but on examining those we meant thus to serve, we find that the heat of the day had sufficiently melted the snow to enclose the wood in a film of ice. As it would be impossible for air to pass through a good ice covering, we found frequently that when such ice scaled off in a change of temperature, the scale, &c., peeled away with the ice ; the more firmly the ice surrounds the branches, the more effectually will it act as an insect-destroyer. Sheeting fruit trees on walls with ice is, therefore, often a benefit; we have consequently found it useful in severe frost to syringe a tree all over, and for convenience and greater benefit to use heated water, as the transition from heat to cold was all the greater. We never knew hardy trees injured by this treatment, whilst the water filled all the crannies in the wall, and made that too a sheet of ice, shutting-up from free access to air what living things might be in holes and crannies. There is, however, one drawback against such a water application to wall trees in severe frost in winter. If the wall should be of stone, soft and porous, or of bricks rather soft and not thoroughly hard burned, if the frost should be severe and continuous, there is a risk that the ice will bring pieces of the wall along with it, and thus accelerate its decay. It is anything but economy to use soft inferior bricks for garden walls. They absorb moisture like a sponge, and when once the outside peels off, they become little better for all practical purposes than so much dried hard-pressed mud. We should not like, therefore, to resort to such a plan where the walls were soft. On wood fences there could be no such objection, and we have known of several cases where, from using such inferior bricks, walls would not hold a nail at length, and then it became necessary to front them with wood.

Fruit rooms and late Grapes needed looking over, as lately stated, Pears still being behind Apples as respects keeping. Dahlia tubers, Potatoes, &c., needed more protection from the severe weather. More litter was also placed over Mushroom beds in an open shed.

Protection.—Where a high temperature is required, a little protection over the front glass does much to render less firing necessary, and thus there is less drying the air inside, and less necessity for moistening that air artificially, and in ordinary cases getting the moisture condensed so as to fall over the plants in the house. Common iron roofs not kept thoroughly painted soon show themselves in this way, as every rusty waterdrop leaves a stain behind it. When a high temperature is used moisture must be given in proportion ; but in such weather it is often better to let the temperature fall 5° or 10°, so as still to be safe, instead of using more fire heat and consequently more vapour in dull cloudy weather.

All things in cold pits and frames covered up on Christmas-eve have remained covered up ever since. When the thermometer fell more than 20° below freezing point more litter was added, and in one or two cases even above a layer of snow. In such weather, however, we are loth to disturb a surface-covering of snow, as from its open character and white colour it forms one of our best protectors. We just peeped in at times to find all was cool and yet safe. With continuous covering there must be no incitement to growth.

Such a week clearly demonstrates the importance of a small house in which you can walk and work, over a pit or frame in which one can do nothing without opening the sashes. We should have liked to have done work in frames or pits, but the opening of the sashes, except for a very short time, would have been dangerous in such weather, when even plants at all tender could only be moved by placing them in covered boxes or baskets, to prevent their feeling the extremes of temperature. We would have done more potting and proceeded with more

cutting-making, if, without moving sashes, we could have more easily reached the plants.

Obtaining fresh platforms and repairing others prevented our doing so much as we might have done in houses to which we could gain access. Merely for the sake of getting inside, by opening and shutting a small door, a little house will always be better than a place of the same size where every attention and regulation of the plants must be given from the outside.

We may mention that though the wind seems to be veering to the south, the frost is still as severe as ever, and if it should continue a week or two longer we shall let Calceolarias, young Cauliflowers, &c., remain covered up just as they are. When the thaw comes, the cautions given last week must be attended to. In such weather, where there can be no growth, covering and uncovering each day are little better than labour thrown away.

See what was said lately as respects forcing shrubs, Roses, bulbs, &c. All these will be benefited by a gentle bottom heat and bringing them on by a gradual increase of top temperature, the more gradual the better in every way; the buds break more regularly, and the flowers come finer, and on the whole are sooner fit for gathering.

All forcing of fruit trees, if not far advanced, should proceed very slowly, until this keen frost pass away. With the roots protected, if outside, the frost itself would not be a drawback; it is the foggy, cloudy weather that, when much heat is used, causes growth to be more weak and juicy than when we can have the help of more sunshine. Many tubers and bulbs may now be potted, and placed in a cool place. Some of the earliest tuberous Gesneras, may be put in pans until growth is progressing, and then the mode of flowering may be decided on. The tubers of Gesnera zebrina do not keep well unless rather dry, and the temperature not long under 50°. The tenderer Caladiums, if dry, will keep in an average temperature of 60°: if much lower for any length of time they shrivel and rot. Most of the Achimenes will be safe in a temperature of from 45° to 50°, either in dry soil or sand. These may be picked out now, and placed in small pans in a mild heat to set them going. The same may be said of Gloxinias, easily wintered under stages, &c. They may now be repotted for early blooming.—R. F.

TRADE CATALOGUES RECEIVED.

B. S. Williams, Victoria and Paradise Nurseries, Upper Holloway, London, N.—*Descriptive Catalogue of Flower, Vegetable, and Agricultural Seeds.*

Charles Turner, Royal Nurseries, Slough.—*Catalogue of Seeds for the Kitchen, the Flower Garden, and the Farm.*

Child & Lorimer, 49, Darley Street, Bradford, and Bradford Nurseries, Shipley.—*General Seed Catalogue and Garden Guide.*

TO CORRESPONDENTS.

*** We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By doing so they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

Books (*Sigma*).—You can have the "Orchid Manual" free by post from our office if you enclose thirty-two post-office stamps, with your address. All the leading nurserymen publish priced and descriptive lists of Camellias. They would send the lists by post if asked. (*G. B. Anstruther*).—The price of the "Cottage Gardeners' Dictionary" with the Appendix, is 6*s.* 6*d.* You can have it free by post from our office for 8*d.* extra. (*A Subscriber*).—"Florists' Flowers for the Many" gives full directions for Pelargonium culture. You can have it from our office post free for five postage stamps.

Cyclamen Seedlings Blooming (*J. Wiggins*).—Though you have not succeeded in blooming them until they were fourteen months old, it is quite certain that others whose communications we have published, have bloomed them when ten months old. Read what they say and are still saying.

Portable Orchard and Greenhouse (*H. C.*).—If the woodwork is not fixed into the wall, nor to the brick foundation, the whole may be removed legally.

Roses (*W. H. B.*).—The Roses named are nearly all of them old sorts, which have been superseded by newer and better ones. François Arago is velvety maroon, a robust grower, and still a good Rose, though too flat. Madame Laffay, red, moderate grower, far surpassed now by other varieties. La Reine, bright rose, large and full, but often opens badly; at times a very fine Rose, but very capricious. Catherine Guillot, deep rose, a Bourbon, and a free bloomer; still worth growing. Reine des Violettes, violet rose, a bad-shaped flower, apt to fade. Jacques Lafitte, deep rose, a strong but coarse flower, and not free; no longer worth growing. Abd el Kader, dark plum, not full, shy bloomer. Of the seven, only François Arago, La Reine, and Catherine Guillot are worth growing, and not one, we think, worth naming in a list of fifty, though if we were planting one hundred varieties, we should find room for them.

Pear (*J. B. White.*)—Colmar Epineux is a synonym of the Passe Colmar.

Nuts (*C. N. B.*).—"Fruit Gardening for the Many" contains what you require. You can have a copy from our office free by post if you enclose five postage stamps with your address.

Sowing Aucuba Berries (*A Subscriber, Tralee*).—When the berries are ripe, which will be known by their parting readily or falling from the plant, sow them in well-drained pans three parts filled with turfy yellow loam two-thirds, and one-third leaf soil, and cover with a thickness of fine soil equal to the diameter of the berries. A gentle watering should then be given, and the pan placed in a cold frame. The soil being kept moist, the seeds will vegetate, if good, in due season.

The Egyptian Melon (*G. S.*).—We believe it is to be had true. It is in the catalogues of trustworthy seedsmen, and many gardeners preserve the seed for home use.

Protecting Pampas Grass (*Anthony and others*).—The following from a correspondent opportunely answers your inquiry—"A good protection for the Pampas Grass is a bamper without the bottom, turned the wrong way up, and filled with dry leaves.—C. L."

Grapes (*A Grower of Grapes*).—If the Tokay Grape that was exhibited was the true one it is an excellent late-hanging Grape, but certainly inferior to the White Muscat of Alexandria. We cannot, on any principle of common sense, understand why at the Darlington Show black Grapes should be judged by appearance and white Grapes by flavour, the black being Lady Downe's and Oldaker's West's St. Peter's, and the white, Muscat of Alexandria and Tokay. If no condition to that effect was given in the rules it is an injustice to exhibitors; and the judges who would act thus on their own responsibility are unfit for their office.

Young Trees Barked by Hares (*J. K.*).—If your trees are barked completely all round to the height of a foot you may take them up at once and plant afresh. If only barked here and there in that space, cover the wounds with some grafting-wax or other similar protection, and dress the whole of the trees within reach of the hares with a thick paste of night soil and stale urine from the stable.

Select Single Fuchsias (*A Subscriber*).—*Dark:* Vesta, Enoch Arden, Lord Derby, Mr. Disraeli, Father Ignatius, and Glowworm. *Light:* Mrs. Bland, Mrs. Shirley Hibberd, Rose of Denmark, Picturata, Brilliantissima, and Guiding Star.

Select Pentstemons. (*Idem*).—Arthur M'Hardy, James Rothschild, Léon Laprevote, Purple King, Flower of the Day, John M'Pherson, Miss Carnegie. Surpasse Victor Hugo, Sunrise, Mrs. A. Sterry Illuminator and Stanstead Surprise. The habit of Christine Nosegay is good, but as we have seen it, scarcely so free-blooming as could be desired.

Angular Flower Beds (*Penumbra*).—These will be duly noticed in Mr. O'Donnell's directions. Your plans are neat but not novel.

Dwarf Fruit Trees (*An Old Subscriber, Bandon*).—Rivers's "Miniature Fruit Garden" and Bréhaut's "Cordon Training" contain the directions you require.

White Flowers for Easter (*R. L.*).—Lily of the Valley, Spiræa japonica, Hyacinths, Narcissus, and Deutzia gracilis are all first-rate. We know of no flowers that sown now would bloom at that time. Crocuses and Snowdrops ought to be planted without delay, and they will flower naturally by the time you name, or if not, they may be placed in the greenhouse a short time previously.

Camellia Leaves Blotched (*J. P.*).—The leaf sent us is blotched by the sun's rays falling powerfully on it whilst wet. The blotching may have been a result of syringing or of condensed moisture falling on the leaves from the roof. The remedy is to give air so as to have the leaves dry before the sun shines powerfully on them, or to shade from very bright sun. We cannot name plants from leaves only.

Azalea Weak (*Inquirer*).—We would not pot the plant until it had flowered, and then we would shift it, giving a good shift; but could you not reduce its ball, and repot in the same size of pot? Two parts of fibrous sandy peat, half a part of loam from turf, and the same of old cow dung, with plenty of sand, will grow Azaleas well. Good drainage is necessary. Encourage fresh growth by a brisk moist heat, shading from bright sun. We think the growth will be stronger another year. We would not top-dress now, but when the buds begin to swell, you may water with manure water, not guano, but sheep droppings, one peck to thirty gallons of water, or cow dung, one peck to twenty gallons. It is not likely you will succeed in getting leaves as large as those of the young plant, for young Azaleas, as a rule, have larger leaves than plants of considerable size and age.

Select Double Petunias (*Idem*).—Mademoiselle Marie de Saint Innocent, Achille Ragon, Victor, Monsieur Darcy, Gloire des Petunias, Honour, or Gazelle.

Ravages of the Titmouse (*W. B.*).—You ask if we have known "Tomtits" take Peas out of the pods. The first year we grew Dickson's First and Best Pea, we found the peas taken out of the pods as they filled. Sparrows were blamed, as they are for everything, but we found the depredations were committed by the small blue Titmouse, or, as it is known in Yorkshire, "Billybiter." About 200 yards away from the Peas the bird had its nest in a wall, and the two old birds came to the Peas, one of them every three minutes, and returned to the nest with a pea for the young. The small blue Titmouse is a great destroyer of fruit tree blossom buds, and is very fond of pecking at fruit, while Peas are its delight. The large Titmouse is fond of bush fruit buds, but we think its attacks end there, at least we have not seen it interfere with anything except Apples and Pears. "Tomtit" in Yorkshire is the Wren, which is a sportive innocent creature, perfectly insectivorous.

Keeping Cut Grapes (*F. C.*).—Cut off 6 inches of the lateral with each bunch, put that lateral into a bottle filled with water, and store in a cool, dry, dark place.

Orchard-house Pots Frozen (*An Old Subscriber*).—A little frost will do no injury to the roots of fruit trees in pots in an orchard house. If the soil at the surface is rather dry, frost will do still less harm; but it is well to protect from severe frost with a little litter or moss over the pot.

Strawberries in Ground Vinery (*Idem*).—To grow Strawberries in ground vineries, the simplest plan would be to grow them in such a place without the glass the previous year, so as to be well established. If you grow them in pots you will be able to remove an unfruitful pot and replace it by another. When so grown the pots should be plunged in the autumn. It matters but little what the material may be—earth, ashes, cocoa-nut fibre, &c., but if in pots we would place a little rich soil beneath the bottom of the pots when the plants showed their flower trusses. Each mode—namely, the planting out and the growing in pots—has its advantages and disadvantages, the first costing least trouble, the second enabling one to make the most of the enclosed space, and, on the whole, getting a rather better return, but with increased labour and nicety in attending to the wants of the plants.

Vines as Bushes (*Idem*).—We do not think that Alicante, Lady Downe's, or Foster's White Seedling Vines will succeed well as bushes in pots in an unheated orchard house, unless the season happen to be brighter and warmer than usual, as was the case last summer.

Glazed Protectors (*Idem*).—Either of the two systems referred to for protecting winter salads, &c., we think is good. Where a high temperature is an advantage in summer, we would prefer brick to wood. We are doubtful of any advantage in winter from the brick walls of such little places. Merely for keeping out frost, we have almost as much faith in a 2-inch board as in a 9-inch wall.

Vines in Pots (*Subscriber for Twenty Years*).—There is less dependance on the age of the cane of a Vine than on its size, and ripened wood and buds. For instance, you may insert single buds now in small pots in a brisk bothed, repot as soon as the little pot is full of roots, and continue repotting until you have the plant in a 15-inch pot, giving it always bottom heat and a growing top heat until you have the pot full of roots, and the stem strong and well browned by September. Then you might place the plant full in the sun against a fence with a south aspect for a month, and then against a north aspect for a month or six weeks to rest it, even by darkness, if the leaves are all off. You could start that plant again, and get good fruit from it in from twelve to sixteen months from the time of inserting the buds. To do this there must be no neglect, no want of nourishment, &c. Fine fruiting canes may be obtained more easily, but with nearly double the expenditure of time, by not giving the plants so much attention the first year, getting them well ripened in 6 or 8-inch pots, keeping them over the winter, cutting the plants down to a bud, and then starting them early, and putting them into their fruiting pots in time, so as to have the wood well ripened early in autumn. Were we short of labour power, and meant to do much with pot Vines, we would resort to the latter mode. The first mode will succeed, perhaps, as well, but the attention and care required will be greater. The size of pot we have already alluded to—from 13 to 18-inch pots, will ripen a nice cane, that would produce from six to nine bunches of fruit, though fewer would be better, and after that the plant would have done all it could, so that fresh plants would be required. Bear in mind the plant must be thoroughly established in the pot early in the previous autumn. There must be no repotting when you force or grow for fruit, but there may be plenty of rich top-dressing. There is no soil better than fresh fibrous loam from rotten turf that has lain long enough to become sweet. To this add about one-eighth of old lime and brick rubbish, and a little more if the loam is at all stiff, and about as much of boiled bones, broken to the size of small beans. In potting, and especially at the last potting, a small handful of such bones may be placed over the drainage. A little sweet rotten dung may be added, as horse droppings sweet and dry. But more will depend on a rather open compost, firm potting, rich watering, and top-dressing, than on the soil itself being clogged with manure.

Melons Sulphuretted—Pears Ripe (*A Constant Reader*).—Why will not a Melon plant stand sulphur on the hot pipes as well as a Cucumber, they being both of the same family? Why indeed? It is very easy to put a simple question, which the greatest philosopher would be powerless to solve. We speak of the family of man; but how varied in colour, habits, likes, and dislikes! How true is the old proverb, "What is one man's meat is another man's poison!" Setting aside all mere affectation, we find that one lady will rejoice in the odour of certain flowers, whilst the same odour would at once induce giddiness and fainting in another lady. We have known this in the case of sisters, which is rather a closer family alliance than that between the Cucumber and the Melon. We are afraid when we inquire into such causes we shall be forced to own "such things are, just because they are." Our correspondent, however, has alluded to a fact well worth noting, that the leaves of Melon plants will not stand sulphur fumes so hot as Cucumbers will do. Both will suffer if the fumes are too hot. In the case of Melons the pipes should not be more than about 160° in temperature. If a little more, there should be a little air left on. When an injury takes place, it is very often from sun heat meeting the sulphur heat from the pipes before there is a sufficiency of air given. Cucumbers will suffer easily from the same cause, but they will stand fumes from 5° to 10° hotter than Melons. The more robust the plants, the more they will stand, but it is best to err on the safe side. In the case of Pears, after they have become about ripe, the flavour will be improved by their being placed for a few hours in a warmer place. There is nothing "fantastic" in the idea. Such fruit will not keep long afterwards.

Various (*Vicar*).—To strike cuttings, raise seeds of tender plants, and grow Melons and Cucumbers, you ought to be able to command a bottom heat of from 75° to 85°, and a top heat of from 65° to 70°. With a higher temperature, what you gain in time you will generally lose in robustness. We are not calculating on sun heat, when, if the sun is bright and a little air is given early, there may be a gradual rise of from 5° to 15°. For the house referred to—5 feet wide, 7 feet high at back, and 5 feet 9 inches in front—two 4-inch pipes will do for bottom heat, but you will need as much for top heat. In a partly-sunk similar house we have two 3-inch pipes below, and two above, but they are not enough in cold weather without covering. The damp that is troubling you in the new pits, heated by two 3-inch pipes in a chamber below, with a platform of boards, on which the plants stand near the glass, may be owing to the damp remaining in the new walls, to a damp floor in the chamber beneath, to using rather too much water, and to letting it go from the boards to the floor to be raised again by evaporation. The simplest remedy would be to use more heat in the pipes during the day, and give more air in consequence, and in mild weather tilting the sash a little in front as well as at the back. In frosty weather a very small quantity of air at the back will prevent the condensation of moisture on the glass, and thus prevent the moisture falling on the plants. In cold weather a covering on the outside of the glass at night would also remedy the evil. As palliatives, if the floor beneath the flue is wet, remove the wettest, and cover with very dry ashes, better still with lime slacked, and not too fresh. On the boards themselves place a thin layer of dry ashes, and give no more water than is absolutely necessary; and, until you get rid of the damp, lift the pots out that need watering, and replace after the extra moisture has drained away. Most likely some of these hints may be useful, but in a pit kept at from 40° to 45°, the simplest remedy would be more heat and air during the day, and less heat at night.

Names of Fruit (*W. H. S.*).—1, Beurré Diel; 2, Greenup's Pippin; 3, Ravelston Pippin; 4, Hunthouse. (*T. R.*).—1, Winter Franc Réal; 2, Spanish Bon Chrétien; 3, Uvedale's St. Germain; 4, Flemish Bon Chrétien. We do not know the other Apples.

POULTRY, BEE, AND PIGEON CHRONICLE.

THE POULTRY LORE OF 1870.

We are thankful that we have been spared another year to review the past as regards poultry, and truly grateful in these days of war and bloodshed that we have to do only with things of peace.

Although poultry plays but a small part, and enters for little in the food of a people, yet it is not without its importance, and if it were developed to the full scope of which it is capable, it would assume an importance which is hardly deemed possible. The contempt for cookery that makes a pound of meat in England do less for the support of a family than half the quantity does in France, and the Britannic craving for roasted and boiled masses, banish poultry from many tables where it might often appear as a *bonne bouche;* and the two chickens that now serve meagrely to dine three of a family of eight, would form the foundation of a savoury and wholesome dish sufficient to dine all. In the course of our remarks we shall have to note a wonderful increase in many breeds, but we shall never get them large enough to supersede the leg of mutton or the sirloin. Our purpose would be fully answered if we could by any labour or remarks of ours introduce them to tables where they are now only seen on very rare occasions, as weddings, christenings, and the like.

We have no increase to note in Dorkings; indeed, we do not see how it is possible we should have. They have almost attained their limit. Cocks of 12 lbs. and hens of from 8 to 10, would almost justify us in thinking the breeders of these birds have been trying to qualify them for becoming joints. We have been glad to see many new names among the prize-takers, and this not to the exclusion of time-honoured exhibitors, but as recipients of the extra prizes called for by the numbers of entries.

There is no progress to call for special mention among the Spanish. They are not so numerous as they were some years since; and although, taken as a class, they are of superior average merit, yet we do not think the most distinguished among them are equal to those that held the same high rank ten years ago. We should be sorry to see them decline. They have a rare merit, inasmuch as they may be kept in health where others would die, and their plumage enables them to live in towns without losing beauty.

Our old friends the Cochin-Chinas hold their own: Buff and Cinnamon, Grouse and Partridge, and the White. We have had most excellent birds of all these commonly shown in 1870. If we were asked to name the colour in which there has been most progress, we should be disposed to give the palm to the Grouse. They have been largely exhibited at all the leading shows, but are seldom found at the purely agricultural meetings. They are kept by dwellers in towns, and at the suburban villas, but they find no favour with the farming interest.

Brahmas now form one of the largest classes, so large, indeed, that it has been necessary to divide them; and instead of the one or two pens of Light birds seeming out of place among their Dark brethren, they form a large item in every show. There has been wonderful progress in these birds; immense weight and perfect plumage are attained. Those who are familiar with our ideas know we are not lovers of crosses; but if any cross is useful, we believe it is one between the Dorkings and Brahmas. The latter take somewhat from the delicacy of the flesh of the former, but make ample amends by the strength of constitution they infuse.

We have been very pleased to see an increase in the entries

of Polands, the birds composing them being of high merit. They are great ornaments to a show.

The Hamburghs in their different classes have sustained their old reputation. The Capulets and Montagues of the Spangled, represented in the feuds of hen tails and full tails, have ceased the wordy war of bygone days and adnoted the decisions of judges; a hen tail is now never seen. The pencilling of the Golden is very superior to that of the Silver, and a desideratum appears accomplished, inasmuch as in many pens we have seen the tails as well pencilled as any other part of the body. We think the Golden birds of both breeds have been shown as nearly perfection as is possible, and certainly superior to the Silver. The recent introduction of classes for Black birds of this breed has added a beautiful variety to our exhibitions. The glossy black plumage, the bright red comb, and the pure white deaf ear, form a striking contrast.

Black and Brown Red Game run a neck-and-neck race. When looking at the Black we award them the palm, but when we come to the Browns we reverse our decision. It is certain both are nearly perfect. Old cockers sometimes grumble, and say "the birds of the present day are too leggy." The other Game classes make little progress, and we are sorry to see a falling-off in the Duckwings. We know no more beautiful bird in our eyes than the Duckwing Game cock.

But very few years since the French breeds showed an occasional pen in the Variety class. Then there were two; then more; and at last an experiment was tried by offering prizes for any French breeds; then they were divided, and now the Crêve-Cœurs and Houdans form large classes. The La Flèche have been failures. Those who appreciate large eggs and plenty of them, will like the Crêve-Cœurs; those who care not so much for large eggs, but want hardy fowls, will like the Houdans. We can say little in favour of the La Flèche; they are good for the table, they lay large eggs, but they lack constitution, or the climate here is unsuitable to them; they are well in the morning, and at night, without any visible reason, they are at death's door.

Malays, once so popular, have now few admirers, if we may judge from their entries. The beautiful Sebrights seem losing ground. Some one should step in to the rescue; they are far too beautiful to be allowed to lose merit, and, being a composite breed, they go back if not renewed from time to time. The Blacks and Whites are hardly shown so good as they used to be. The Game have irresistible charms for Bantam-breeders. They are bred to high perfection, and their entries are sufficiently numerous to justify an increase in the number of prizes offered for them. The quaint Japanese Bantam is exhibited in considerable numbers. They are familiar little creatures, and from their attachment to man, would seem to be among fowls like the Robin among birds. While speaking of Bantams, it would be unjust not to mention the beautiful Buff Cochin Bantams that have been seen at some of the shows during the past year.

In every way the Aylesbury Ducks have quailed before the Rouens; their numbers have been fewer, and their weights less. The Rouens now form the largest class. The Black Buenos Ayreans have shown well, but will still bear reducing in size. A pair of Mandarins or Carolinas caused a sensation a few years since, but they are now shown by dozens.

Geese go on increasing. The Whites hold their own in weight, but the Toulouse are far more numerous. In both classes birds of 28 lbs. each are required for first-prizetakers—no mean success, when we consider that a few years ago 9 lbs. were the average, and 14 lbs. a marvel. Turkey cocks have been shown 30 lbs. in weight, young birds of the year more than 20, and young hens of 15 lbs. each.

These are some of the results of careful breeding, and they are not mean ones. When we are sufficiently advanced to have correct statistics of poultry sold for food, those who now speak lightly of it will alter their opinions. It may safely be said that of late years, since the poultry movement took place, fowls, Geese, Turkeys, and Ducks have increased nearly a third in weight. If we could ascertain the numbers that are sent to market, and thereby publish the extra amount of food produced only by choosing the breeds adapted to the places where they are to be kept, and by proper and judicious feeding, it would astonish many, by showing the enormous increase in the delicate food for which we are indebted to the poultry-yard.

The progress has not been confined to this one part of the question. In the early days roup was the bane of the breeder. Two or three days' confinement, a fortnight's damp cold weather, or a prevalence of east wind caused it to appear. Birds were bred in-and-in, they were little cared for, and they took their revenge by their proneness to catch any disorder from which a few of the yard were suffering. At shows a good part of a class was often removed because the fowls composing the pens were diseased. It was never safe to turn down fowls that had been to a show till they had performed quarantine. Now show after show may be visited without seeing a diseased bird. It is not only at shows this is observed, but its happy effect is seen in every yard and run. The result has been attained without expense. It is the reward of more careful breeding and of some painstaking. Those who are close observers have seen with much interest the ease with which the requirements of judges have been carried out. The hen-tailed cocks of Hamburghs, the combs and gills of Polands, the drooping combs of Spanish, and many other such defects are now never met with.

When we come to the question of eggs we again lament the want of statistics. Hundreds of millions are consumed every year, many of them imported. Notwithstanding the war, the number of eggs, more than 22 millions, imported from France last November, was about the same number as imported in that month of 1869. In every way the production of eggs is too little cared for in England.

We have concluded our poultry lore, but gratitude compels us to say a few words of ourselves. We profess, as poultry chroniclers, to hold an impartial balance on all matters connected with the subject. We deprecate anything like personality, and while we give an outspoken opinion on every question that comes before us, we can safely say we never knowingly print a line that shall cause pain. We have our reward in an increased and increasing circulation, and in the confidence of our readers. We thank them for it. We pledge ourselves to continue a line of conduct consonant at once with our feelings, and productive of our readers' approval. We thank our subscribers, readers, and contributors, and we heartily wish them all

A Happy and Prosperous New Year.

THE ANY VARIETY CLASS.

I quite concur with the remarks of "Y. B. A. Z.," and think that the "Any other variety" classes should have awarded not less than six prizes to them, as such classes generally bring together many varieties of fowls that are seldom seen, and birds of superior merit. When four and even six varieties are brought together, how can a judge do justice to the whole if only two or three prizes are given?

"Y. B. A. Z." says that Malays ought to have a class to themselves at all established shows, and so I think, as it is not fair to see Malays classed against Black Hamburghs, Saltans, and Polands. At the Durham Show a pen of Malays was not even commended, and this pen had taken honours at Birmingham three times. The first prize went to Black Hamburghs; the second to a pen of Malays—a pen, I understand, which gained prizes at Birmingham and the Crystal Palace.—R. D.

CARBOLIC ACID AND INSECT VERMIN.

The *Canadian Poultry Chronicle* for December contains the following valuable remarks on this subject, which I know will be useful to many readers here:—

"All amateurs and poultry-breeders are but too well aware that parasites are the pests of poultry houses, more especially in towns and cities, where poultry are kept within confined limits. Without, as the owner thinks, any real cause, the fowls begin to droop and look sickly, and, after a little, one by one die off. He then becomes alarmed; examines them, and finds them covered with parasites; he looks into his fowl house and examines the cracks and chinks in the boards, and finds them filled with insects, living insects. He is astonished; he cannot account for it; and then the question arises in his mind, 'How can I get rid of them?' Scores of times within the last few months has this question been asked of us, and our answer invariably has been, Use carbolic acid.

"But how to use it is a matter of importance. There can be no doubt about its efficacy, but it becomes everyone to exercise care in handling it. The acid is sold by all druggists in its crystalline and liquid form. In crystals, it dissolves in twenty times its weight of water—that is, 1 oz. of the crystals requires 20 ozs. of water to dissolve them. Thus dissolved, it is entirely too strong for any ordinary use. Dr. Emerson gives recipes for preparing this powder for disinfecting and other purposes.

As a whitewash for walls, for protection against insects, bugs, &c., he says, 'Put 3 ozs. of carbolic acid into 12 quarts of lime-water or whitewash.' Whitewash the walls of the poultry house well with this wash, and no more living parasites will be seen; their death is inevitable. A weak solution may be made to wash fowls in: one part of the acid to sixty parts of warm water; let it cool, then dip the fowls in it until the feathers become thoroughly wet and the solution reaches all parts of the body. Afterwards place the fowls on clean dry straw, where the sun will reach them, until they are dry."

I may add to the foregoing that the most handy and useful thing I know of to have about the poultry yard is carbolate of lime. It is a powerful and at the same time pleasant disinfectant, whilst it will also answer most purposes in the way of destroying insects, if dusted liberally against the walls or other infested parts. Being a powder, it may also be dusted amongst the straw in the nests, and in other places where a liquid cannot be used; though in very bad cases the more searching wash above given will be necessary. The price in most towns is about 4*d.* per pound, and a regular sprinkling on the floors of the houses, I can say from experience, adds greatly to the comfort of all concerned.—L. Wright.

EXHIBITION GAME COCKS.

I most fully concur in the remarks on Game fowls in your last number by your correspondent "Yorkshire." Some of the specimens of the Brown Reds shown at many exhibitions really put one in mind, so to speak, of a cross between "a Malay and an Ostrich," if such a cross were possible. The brassy or straw-coloured Brown Reds, especially, that I have seen at exhibitions, were very poor things as Game cocks, standing in their pens, with tails carried horizontally, and hiding their heads in the farthest corners of the pen without crowing at all. I have, however, seen some excellent cockers' birds of this colour, called in some places brass cocks. Those birds I allude to were bred from good dark-legged Brown Red cocks put to good yellow-legged Duckwing hens, and were great favourites and very quick birds. Our judges of Game fowls certainly keep up the wrong type, in the exhibition Brown Reds more especially, though I do not like a full-feathered bird resembling a farmyard Game cock.—Newmarket.

BRISTOL AND CLIFTON POULTRY SHOW.

The total entries for this Show, the judging of which takes place to-day, are 1306, which, by an extraordinary coincidence, are just one more than last year. From information which has reached us we are able to say that in many of the classes there will be the best show of the season. Partly in consequence of the retarding influence of the dry season many of the finest chickens have not been previously ready for exhibition, and in nearly all the classes there are entries, from eminent exhibitors, of first-rate birds never before shown.

The Spanish as usual are in great force, the cockerels numbering thirty-three and the pullets twenty-three entries. We hear, also, that a better show of Buff Cochins than has yet been seen this year is anticipated. But the most remarkable classes will be the Dark Brahmas, which in numbers have beaten every other breed. The cockerel class contains the extraordinary number of forty-five entries, and the others are in proportion.

With the exception of Bantams and Pigeons, the pens at this Show will be, as usual, arranged in single tier, while for light the exhibition hall has perhaps no equal. Altogether, both to the experienced and the tyro, this Show will offer opportunities and advantages for the real study of their pet hobbies which have not previously offered during the present season, and which none who can enjoy should lose sight of.

THE FLYING OR SKY TUMBLER.

Two peculiarities are omitted in the description of this class of Tumbler in your Journal of December 29th, and which the Birmingham Columbarian Society will accept, perhaps, from an amateur. I refer to the occurrence of clear-legged and odd-eyed birds (a hazel and a pearl eye), in the Birmingham Muffed Tumbler broods from parent birds both muffed in legs, and with pearl or silver eyes, and *vice versâ*—*i.e.*, muffed-legged and silver-eyed brood from clear-legged and odd-eyed parentage. So it occurs in my own flight of about a score of these muffed Tumblers had from Birmingham, and I presume the occurrence is not an exception.

Allusion is made, in the description I mention, to a Dutch import of this variety of Tumbler, and, I think, very appropriately; for doubtless the Birmingham Roller or Tumbler is a cross between our own old English and the European Dutch or German feather-legged Tumbler, "improved upon," certainly, by English blood. Hence the occasional clear leg appears; the odd eyes dating back, however, I cannot guess whence, save of hazel-eyed, Bald, or Magpie ancestry. Can the Birmingham Columbarian Society inform us further upon the features I have noticed?

As additional testimony to the cross suggested, the Birmingham Tumblers derive, I infer, their high or sky-flying propensity from our English blood, and their rolling properties from the continental admixture.

What "Young England" fancies is our own dainty, fairy little Sky Tumbler, innocent of feathered legs, red as coral, with eyes of transparent pearl and studded jet, and in all colours, from those of the harlequin Almond, ermine Mottle, and varied Splash, to the sombre selfs—red, black, yellow, silver, drab, and blue—birds not heavier than a Starling, and whose home appears to be in cloudland or on the roof alike, as caprice or nature prompts.—Reader.

INQUIRY.

I advertised in your Journal some Call Ducks, and amongst other applications received one from W. George & Co., poultry merchants, 42, Great Wild Street, Covent Garden, for four pairs, and another from George White, 147, Culford Road, N., for six couple. I replied, giving a reference to a tradesman in London, and requesting post-office order before forwarding the birds. I have heard nothing further. Does any reader of this Journal know them?—J. N. Preston.

MANCHESTER POULTRY AND PIGEON SHOW.

(*From two Correspondents.*)

The tenth and most successful poultry and Pigeon Show ever held in Manchester took place on the 30th and 31st of December. On both days the attendance of visitors was very great, and, to some extent, will recoup the spirited proprietors for the loss they must have sustained last year, when, if we remember aright, it rained nearly all the time of the Show. The arrangements were excellent, and if any fault could be found, we thought it would have been much better, both for the poultry and Pigeons, had the magnificent rooms been better heated.

Old Coloured *Dorking* cocks were rather a poor class, nearly all bad in feet or toes, yet there were several very large birds amongst them. The hens were very good in quality, but not numerous. The cockerels were a very good class, which was well filled. The class for Coloured pullets consisted of a remarkably good lot of birds. Silver-Grey Dorkings were not good. All the *Spanish* classes were very good, but many of the birds showed signs of suffering from the severe weather; in fact, a few were so affected with the frost, that they would have been far better at home. The first-prize hens were claimed at £15 immediately the Show opened. The *Cochin* classes were all remarkably fine, though some really good birds appeared quite out of condition from being over-exhibited. The first-prize pair of Buff pullets were in beautiful condition. The Dark *Brahmas* were both remarkably good classes, but, as in the Cochins, a few of the best birds were in bad condition. Light Brahmas were not good. *Poland* cocks were excellent, and a few of the hens were as good as could be wished for. The *Game* classes were the best by far in quality I have seen this season. All the classes were remarkably good and well filled.

Ducks, *Geese*, and *Turkeys*, as may be seen by the prize list, were wonderful.

In *Hamburghs* the Spangled were good, and very far better than the Pencilled. *Bantams* were worth a long journey to see, and no class in the Show was more crowded than the Game Bantams.

PIGEONS.

In the Pouter classes, unfortunately for Mr. Gamon, of Chester, his four fine birds were entered in wrong classes, otherwise we feel sure some of them would have been in the prize list; and, again, a pair of his splendid Yellow Dragoons were passed over, owing to the hen bird being marked, she having a piece of string tied round one of her legs.

There were 307 entries of Pigeons, and representatives from most of our best lofts. Many pairs of Pigeons arrived too late for competition, we believe the whole of those belonging to Mr. Van Haansbergen and Mr. Sharp, of Johnstone. The judgment appeared to give almost universal satisfaction, and we never heard fewer complaints, although a few unsuccessful exhibitors, as usual, attempted to convince novices their unnoticed pens were better than the best.

The Pouters were good; Black Carrier cocks excellent, numbering fourteen pens, the winning birds being placed the same as at Birmingham Show. Black Carrier hens were very good. Had pen 1043 been

owned by an artist, it would have taken the first prize. Dun cocks we thought were a poor lot, but the hens made up for them; what should have been Blue Carriers were mostly slate-coloured, but they are improving. The Yellow Dragoons were all good, the first prize being won by, we are told, the same pair that took the silver cups at the Crystal Palace and Bingley Shows. In "Any other Coloured Dragoons," the most magnificent pair of Reds we have seen for many years deservedly were first. We were informed they were bred by the London fancier who bred the first-prize Yellows. Blues were second. All the birds in the class were good, and very properly highly commended.

There were twenty-eight entries of Antwerps, but neither Judges nor exhibitors appear to know what they want. The first prize went to a pair of hard-coloured, useful-looking Blue-chequered, and were claimed for £5; the second-prize birds were Mealy-ash. Jacobins, excepting those which took the first prize, were only moderate. The second-prize pair we took for two cocks. What has become of all the good Jacobin fanciers? Mr. Firth was first and second in Barbs with, perhaps, two of the best pairs in England, the first-prize cock being a wonder.

There was a lot of good Blue (or should-be Blue) and also White Fantails, but many of the Whites appeared to be suffering from overshowing. Almond Tumblers were very good, also the Beards, Balds, and Any variety of Tumblers. The Nuns, the poor Nuns! the whole class were disqualified for over-trimming; it is but just to Mr. Graham and Mr. Haansbergen to say that they were not included, their birds not being sent, or had not arrived. The two prize pairs of Magpies were charming. Turbits were also very good, particularly the first-prize pair; but here, again, pens 1221 and 1224 were disqualified for being so badly oiled.

Swallows and Archangels were fair. English Owls were very good, and many pens reminded us of the time when foreign ones were not known at our shows. The improvement in this breed has been very marked the last few years. The foreign Owls were very good. The first-prize Runts weighed 4 lbs. 12 ozs.

The whole class of Trumpeters was splendid; first Black, second a beautiful pair of Whites. The birds in the Any variety class were all pretty. We very much admired a pair of Dutch Pouters shown by Mr. Tegetmeier.

Dorkings (Coloured, except Silver-Grey). — *Cock.* — 1, J. White, Warlaby. 2, D. Parsons, Cuerden, Preston. 3, Admiral W. Hornby, Knowsley. *hc*, R. D. Holt, Orrest Head, Windermere. *c*, Mrs. F. S. Arkwright, Sutton Scarsdale, Chesterfield; S. H. Stott, Quarry Hill, Rochdale.

Dorkings (Coloured, except Silver-Grey).—*Hens.*—1, Mrs. F. S. Arkwright. 2, J. White. 3, Admiral W. Hornby. *hc*, T. Briden, Earby, Skipton; Hon. H. W. Fitzwilliam, Wentworth Woodhouse; Henry Lingwood, Barking, Needham Market; W. W. Ruttlidge, Shortend, Kendal.

Dorkings (Coloured, except Silver-Grey).—*Cockerel.*—1, Mrs. E. Wheatley, Ingatestone. 2, Mrs. T. W. L. Hind, Kendal. 3, H. Pickles, jun., Earby. *hc*, T Briden; Miss Davies, Chester (2); R. D. Holt; J. Longland, Grendon, Northampton; Rev. F. Taylor, Kirkandrews Rectory, Longton; J. White (2). *c*, Mrs. F. S. Arkwright; H. Lingwood, Barking, Needham Market.

Dorkings (Coloured, except Silver-Grey).—*Pullets.*—1, Mrs. E. Wheatley. 2, Mrs. F. S. Arkwright. 3, W. H. King, Sandfield, Rochdale. *hc*, Rev. E. Bartrum, Great Berkhamustead; Mrs. F. S. Arkwright: Miss Davies; Miss Fairhurst, Ormskirk; T. L. Jackson, Bash of Ewes, Langholm; J. Longland W. Harvey, Sheffield.

Dorkings (Silver-Grey).—*Cock.*—1, T. L. Jackson. 2, Hon. H. W. Fitzwilliam. 3, Hon. J. Massey, Limerick.

Dorkings (Silver-Grey).—*Hens or Pullets.*—1, R. D. Holt. 2, J. Longland. 3, W. W. Ruttlidge. *hc*, T. L. Jackson; R. Smalley, Lancaster. *c*, Rev. J. F. Newton.

Dorkings (Rose-combed or Any other variety).—1, Miss Fairhurst. 2, D. Parsons. 3, Miss E. Williams, Henllys Berriew. *c*, Countess of Aylesford, Leamington Spa.

Spanish.—*Cock.*—1, H. Lane, Bristol. 2, C. W. Brierley, Middleton. *hc*, Burch & Boulter, Sheffield; Hon. Miss D. Pennant, Penrhyn Castle, Bangor (2). *c*, J. Thresh; R. Teebay, Fulwood, Preston.

Spanish.—*Hens.*—1, R. Teebay. 2, H. Lane. 3, J. Thresh, Bradford. *hc*, Miss E. Beldon, Goitstock, Bingley; Burch & Boulter; F. & C. Haworth, Newfield, Haslingden. *c*, Hon. Miss D. Pennant.

Spanish.—*Cockerel.*—1, C. W. Brierley. 2, Hon. Miss D. Pennant. 3, H. Lane. *hc*, W. R. Ball; R. Davis; F. & C. Haworth; Hon. Miss D. Pennant; J. Thresh; C. W. Brierley. *c*, Burch & Boulter; J. Mansell, Longton, Staffordshire.

Spanish.—*Pullets.*—1, W. R. Ball. 2, Hon. Miss D. Pennant. 3, R. Teebay. *hc*, H. Lane; J. Thresh.

Cochin-China (Cinnamon and Buff).—*Cock.*—1, H. Yardley, Birmingham. 2, E. Thomas, Barlow Moor, Didsbury. 3, T. Stretch, Ormskirk. *hc*, W. A. Burnell, Southwell (2); W. A. Taylor, Manchester; R. White. *c*, N. Dawson, Beverley; W. Sandy.

Cochin-China (Cinnamon and Buff).—*Hens.*—1, W. A. Burnell. 2, W. A. Taylor. 3, W. Sandy, Ratcliffe-on-Trent. *hc*, C. Felton, Birmingham.

Cochin-China (Cinnamon and Buff).—*Pullets.*—1, J. Sichel, Timperley. 2, Henry Lingwood. *hc*, T. Bracegirdle, Sale, Manchester; Henry Lingwood, Barking, Needham Market; T. Stretch; W. Sandy.

Cochin-China (Brown and Partridge-feathered).—*Cock.*—1, T. Stretch. 2, E. Leech, Rochdale. 3, E. Tudman, Whitchurch, Salop. *hc*, Mrs. R. White, Sheffield; J. A. Taylor. *c*, Furness & Sudall, Haslingden.

Cochin-China (Brown and Partridge-feathered) - *Hens.*—1, J. A. Taylor, Manchester. 2, E. B. Wood, Uttoxeter. *hc*, T. Stretch; E. Tudman.

Cochin-China (Brown and Partridge-feathered).—*Pullets.*—1, J. A. Taylor. 2 and 3, H. Crossley, Broomfield, Halifax. *hc*, T. Stretch; P. H. Jones, Fulham. *c*, Horace Lingwood, Creeting; J. Palmer.

Cochin-China (White).—*Cock.*—1, R. Smalley. 2, J. Sichel. *hc*, H. Yardley.

Cochin-China (White).—*Hens or Pullets.*—1, R. Smalley. 2, J. Sichel. *c*, F. and C. Haworth.

Brahma Pootra (Dark).—*Cock.*—1, Hon. Mrs. A. B. Hamilton, Woburn. 2, J. H. Dawes, Birmingham. 3, J. S. Tainton, Gloucester. *hc*, W. Hargreaves, Bacup; Horace Lingwood; Hon. Miss D. Pennant (2); W. Whiteley, Sheffield. *c*, T. F. Ansdell, St. Helen's; J. H. Dawes.

Brahma Pootra (Dark).—*Hens or Pullets.*—1, E. Leech. 2, H. Lacy, Hebden Bridge. 3, Mrs. A. Hurt, Alderwasley. *hc*, T. F. Ansdell; Mrs. A. Hurt; H. B. Morrell, Caemawr, Clyro; Hon. Miss D. Pennant; E. Ryder, Hyde; J. Sichel; J. Watts, King's Heath, Birmingham; W. Whiteley. *c*, H. P. Moor, Chippenham; H. B. Morrell (2); W. Whiteley.

Brahma Pootra (Light).—*Cock.*—1, W. T. Storer, Brewood, Stafford. 2, A. O. Worthington, Burton-on-Trent. 3, F. Crook, Forest Hill. *hc*, J. Pares, Postford, Guildford. *c*, H. Dowsett, Pleshey, Chelmsford.

Brahma Pootra (Light).—*Hens or Pullets.*—1, J. R. Rodbard, Wrington, Bristol. 2, F. Crook. 3, A. O. Worthington. *hc*, H. Dowsett; J. Pares; W. Whiteley.

Polands (Any variety).—*Cock.*—1 and 3, G. C. Adkins, Lightwoods, Birmingham. 2, W. Harvey. *hc*, Miss E. Beldon; W. Gamon, Chester; J. S. Senior; P. H. Jones.

Polands (Any variety).—*Hens or Pullets.*—1, G. C. Adkins. 2, Miss E. Beldon. 3, T. Wakefield, Golborne, Newton-le-Willows. *hc*, W. Harvey.

Crève-Cœur.—1, W. O. Quibell, Newark. 2 and *c*, C. H. Smith, Ratcliffe-on-Trent. 3, Miss E. Beldon. *hc*, W. Bonteher, Notting Hill

Houdans.—1, R. B. Wood. 2, W. O. Quibell. 3, J. Sichel.

Game (Black-breasted Reds).—*Cock.*—1, S. Beighton, Farnsfield, Southwell. 2, E. C. Gilbert, Penkridge. 3, T. Mason, Green Ayre, Lancaster. *hc*, C. Chaloner, Whitwell, Chesterfield; W. H. Stagg, Netheravon, Marlborough. *c*, J. Frith.

Game (Black-breasted Reds).—*Hens.*—1, C. Chaloner. 2, J. Douglas, Clumber. 3, J. Forsyth, Wolverhampton. *hc*, P. P. Lyon, Knotty Ash, Liverpool. *c*, G. Bagnall, Draycott, Cheadle.

Game (Black-breasted Reds).—*Cockerel.*—1, S. Beighton. 2, J. Douglas. 3, W. Boyes, Beverley. *hc*, E. Bell; C. Chaloner; G. Bagnall; J. Mason; W. H. Stagg. *c*, J. Frith, Chatsworth

Game (Black-breasted Reds).—*Pullet.*—1, W. Dunning, Newport, Salop. 2, J. Holland, Manchester. 3, W. J. Pope, Biggleswade. *hc*, T. Bottomley, Shelf, Halifax; C. Chaloner; D. Harley, Edinburgh; E. Mann, Wallfield Stand, Manchester; W. J. Pope; G. Bagnall. *c*, J. Mashiter, Ulverstone; C. W. Brierley.

Game (Brown and other Reds, except Black-breasted).—*Cock*—1, J. Bowness, Newchurch. 2, C. W. Brierley. 3, J. Wood, Wigan. *hc*, A. Haslam, Hindley, Wigan; Golley & Willet, Nantwich.

Game (Brown and other Reds, except Black-breasted).—*Hen.*—1, C. W. Brierley. 2, J. Wood. 3, F. Sales, Crowle. *hc*, B. Conaterdine, Littleborough; C. W. Brierley.

Game (Brown and other Reds, except Black-breasted).—*Cockerel.*—1, J. Wood. 2, W. Dunning. 3, S. Matthew Stowmarket. *hc*, W. Grice, Bootle; E. Mann (2); W. Sowerbutts, Nantwich; C. W. Brierley; Golley & Willett. *c*, J. Mashiter; T. Statter, Stand, Manchester.

Game (Brown and other Reds, except Black-breasted).—*Pullet.*—1 and 3, C. W. Brierley. 2, W. Boulton, Dalton-in-Furness. *hc*, T. Burgess, Barleydam; J. Mashiter; S. Matthew; W. Sowerbutts. *c*, T. Statter; J. Bowness.

Game (Duckwings, and other Greys and Blues).—*Cock.*—1, J. Halsall. 2, C. Chaloner. 3, S. Matthew. *hc*, C. W. Brierley; W. Boyes. *c*, J. Frith.

Game (Duckwings, and other Greys and Blues).—*Cockerel.*—1, S. Matthew. 2, C. Travice, Thurgoland, Sheffield. 3, J. Frith. *hc*, W. Dunning.

Game (Duckwings, and other Greys and Blues).—*Hen or Pullet.*—1, F. Sales. 2, E. Bell, Burton-on-Trent. *hc*, D. Harley; C. W. Brierley.

Game (Any other variety).—*Cock.*—1 and 2, J. Sunderland, Halifax. *c*, W. Church, Nantwich.

Game (Any other variety).—*Hen.*—1, C. W. Brierley. 2, J. Frith. *hc*, C. W. Brierley; R. & H. Walker, Gomersall. *c*, W. Johnson, Stanley, Liverpool.

Ducks (Rouen).—*Drake.*—1 and 2, T. Statter. 3, C. P. Ackers, Abram, Wigan. *hc*, T. Burns, Abram, Wigan (3); Miss Davies (3); W. Evans, Prescot; W. Gamon; S. H Stott; T. Taylor, Kendal.

Ducks (Ronen).—*Ducks.*—1, J. K. Fowler, Aylesbury. 2, T. Statter. 3, C. P. Ackers. *hc*, T. Burns; W. Evans; S. H. Stott; H. B. Smith, Broughton, Preston; T. Statter; J. Wood; T. Wakefield.

Ducks (White Aylesbury).—1, E. Leech. 2, Mrs. M. Seamons, Hartwell, Aylesbury. 3, J. K. Fowler. *hc*, Mrs. M. Seamons; E. Leech.

Ducks (Black East Indian).—1, S. Burn, Whitby. 2, Rev. W. Serjeantson, Acton Burnell. *hc*, S. Burn. *c*, H. B. Smith.

Ornamental Waterfowl.—1 and 2, J. Jennison & Co., Zoological Gardens, Manchester (2) (Vidnata Whistling Ducks and Carolinas). 3, T. Haslam (Shovellers). *hc*, C. N. Baker, Chelsea; R. B. Smith (2) (Shield and Carolinas); C. W. Brierley; M. Leno, Markyate Street (Mandarins); J. Goodwin, West Gorton (Mandarins); J. Jennison & Co. (3) (Mandarins, Teal, and Tufted Divers). *c*, C. N. Baker (2); J. Knott, Kirmanshulme, Manchester (Pochards); M. Leno (Carolinas); T. Haslam (Brown Chinese Geese).

Geese (White).—*Gander.*—1 and 2, E. Leech (30 lb. 9 ozs. and 30 lbs. 1 oz.). 3, Rev. G. Hustler, Stillingfleet Vicarage, York (29 lbs. 10 ozs.). *hc*, T. Statter, jun. (2).

Geese (White).—*Geese.*—1, E. Leech (37 lb. 4 oz.) 2, Rev. G. Hustler (49 lb. 14 oz.). 3, J. & W. Rostron, Levenshulme, Manchester (46 lb). *hc*, T. Statter, jun.

Geese (Grey and Mottled).—*Gander.*—1, Mrs. M. Seamons (33 lb. 6 oz.). 2, J. K. Fowler (32 lb.). 3, E. Leech (29 lb. 4 oz.). *hc*, J. Lycett, Stafford; E. Leech.

Geese (Grey and Mottled).—*Geese.*—1, W. Tippler, Chelmsford (41 lb.). 2, E. Leech (41 lb). 3, H. Crossley (39 lb.). *hc*, J. Lycett; Rev. G. Hustler.

Turkeys.—*Cock.*—1, F. Lythall, Banbury (34 lb. 15 ozs.). 2 and 3, E. Leech (32 lb. 7 oz. and 32 lb. 6 oz.) *hc*, J. Kershaw, Heywood, Manchester; G. R. Pearson, Witham Common, Grantham; Rev. N. J. Ridley, Newbury.

Turkeys.—*Hens.*—1, E. Leech (37 lb. 2 oz.). 2, F. E. Rawson, Thorpe, Halifax (36 lb. 11 oz.). 3, Rev. N. J. Ridley (29 lb. 14 oz.). *hc*, Mrs. J. Mayhew, Great Baddow; E. Leech; G. R. Pearson.

Extra Stock (Any variety).—1, Furness & Sudall (Cuckoo Cochins). 2, Hon. H. W. Fitzwilliam, Wentworth Woodhouse (La Flèche). *hc*, W. A. Hyde, Ashton-under-Lyne (Japanese Silkies); J. Kitchen, Penistowles, Blackburn (Anconas); Mrs. R. Taafe, Plunket, Ireland (Black Cochins).

CARRIERS (Any colour except Black or Dun).—*Cock.*—1 and 2, J. C. Ord, Pimlico. *Hen.*—1, R. Fulton. 2 and *hc*, J. C. Ord.

DRAGOONS (Yellow).—1, J. Holland, Manchester. 2 and *vhc*, F. Graham, Birkenhead.

DRAGOONS (Any other colour).—1 and 2, J. Holland. *hc*, J. T. Dorrington, Didsbury.

ANTWERPS.—1, J. Williams, Manchester. 2, Mrs. F. S. Arkwright, Sutton Scarsdale, Chesterfield.

JACOBINS.—1, J. Williams. 2 and *c*, E. E. M. Royds, Rochdale.

BARBS.—1 and 2, J. Firth. *hc*, R. Fulton.

FANTAILS (White).—1, C. Bulpin, Bridgwater. 2, J. F. Loversidge, Newark.

FANTAILS (Any colour except White).—1, J. Elgar, Osmanthorpe Hall, Newark. 2, P. H. Jones, Fulham.

TUMBLERS (Almond).—1 and 2, R. Fulton. *hc*, J. Ford, Monkwell Street, London. *c*, E. Horner.

BEARDS OR BALDS.—1 and 2, J. Fielding, jun., Rochdale. *hc*, W. H. C. Oates, Besthorpe, Newark.

TUMBLERS (Any variety).—1, R. Fulton. 2, J. Ford.

NUNS.—(*The whole class having been so evidently trimmed, the Judges declined awarding any prizes.*)

MAGPIES.—1 and 2, E. Horner.

TURBITS.—1, F. Mangnall, Handford. 2 and *hc*, W. Bankes, Runcorn.

SWALLOWS.—1 and 2, E. Horner.

ARCHANGELS.—1, C. Bulpin. 2, W. Harvey.

OWLS (English, Blue and Silver).—1 and 2, F. Mangnall. *hc*, W. Bankes; P. H. Jones.

OWLS (Foreign).—1 and *vhc*, J. Fielding, jun. 2, W. Harvey. *hc*, P. H. Jones.

RUNTS.—1, S. A. Wyllie, East Moulsey. 2, H. Yardley. Extra 2, P. H. Jones.

TRUMPETERS.—1, J. Firth, Dewsbury. 2, W. H. C. Oates.

ANY OTHER VARIETY NOT BEFORE NAMED.—1 and 3, W. B. Tegetmeier, Finchley. 2, J. Baily, jun., Mount Street, London (German Toy). *hc*, H. Yardley (2).

JUDGES.—*Dorkings, Spanish, Cochins, French Breeds, Extra Stock, and Bantams, except Game:* Mr. E. Hewitt, Sparkbrook, Birmingham. *Brahmas:* Messrs. Hewitt and Teebay. *Game and Game Bantams:* Mr. R. Teebay, Fulwood, Preston. *Hamburghs, Polands, Ducks, &c:* Mr. J. Dixon, North Park, Bradford, Yorkshire. *Ornamental Waterfowl:* Messrs. Dixon and Hewitt. *Pigeons:* Dr. Cottle, Cheltenham; and Mr. T. H. Ridpeth, Outwood Hall, Handforth, Cheshire.

ULCERATED FEET OF BIRDS.

IN your Journal of November 3rd (page 362) I observe a question about a Bullfinch's feet being swollen, and Mr. Blakston says it arises from the cage, &c., not being kept clean. Now this cannot be, as I knew several kept in a room afflicted with bad feet. I have observed that Bullfinches seem more subject to this complaint than other birds, but I have known Canaries affected with it. It comes on with a sort of swelling, and goes on, if not stopped, till the foot suppurates, and off drop the claws and sometimes the foot. I found out a cure for it in one-fourth of the solution of chloride of soda, and three parts of boiled rain water with just the chill off, put into a little galleypot, and the bird's feet put in twice or thrice a-day. The same water will do for a day or so, but it must be kept corked up, as this solution is a solution of soda impregnated with chlorine gas, and not as many of the chemists will tell you, common salt. I have known this cure birds after one or two of the claws have dropped off, and it may be of use to many of your readers.—A. Y.

WINTERING BEES.

WINTER has come at last, the fields this morning are all white with snow, but our little favourites, sheltered by their warm and well-protected habitations, can bid defiance to the storm. Nevertheless, so long as snow lies on the ground, they are not altogether safe from danger, or beyond the reach of destructive influences. The warm rays of an unclouded sun playing upon their hives will arouse them from their slumbers, and, attracted by the bright light reflected in at their doors, they are liable to be allured outside, where certain death awaits them. These deceitful influences would be counteracted were the cold sufficiently intense to cause a timely retreat to be beaten, but a very low temperature is not necessarily an accompaniment to a fall of snow. When the earth wears her most wintry aspect, a great degree of mildness may prevail, and the bees are not slow to take advantage of it for an airing. This they can do with perfect impunity when the surface of the snow is crisp and hard, but the case is altered if it happens to be in what may be called a soft floury condition. Could bees fly out and return again without halting, the effects would be beneficial; but it is their practice as soon as they have accomplished the object for which they left their hives, to seek for a resting place. The act of relieving themselves of a burden which has been carried for some time, seems utterly to exhaust them. After laying it down they not unfrequently fall to the earth or reel about as if intoxicated. Now, either to fall or settle upon snow in a floury condition is attended with fatal results, for they at once sink down into it, and their energies being exhausted, they cannot recover themselves in time to escape being hopelessly chilled.

It is a sad sight for a bee-master to witness the loss of a number of valuable lives, which a little foresight and trouble might have prevented. The plan of collecting these fallen and seemingly dead victims of misfortune, and reviving them again by the application of a little heat has often been tried, but I never found it turn to good account, and I can remember one instance when it was attended with positive harm. Bees thoroughly benumbed in snow do not appear capable of enduring a lengthened confinement immediately afterwards, and many of them that failed to accomplish the purpose for which their outside flight was undertaken are not careful, as formerly, to keep their hives pure and clean.

Various methods for preventing deaths happening amongst the snow have been recommended, and all of them are worthy of notice. Some advise that the hives, as soon as winter has set in, be turned round on their stands, so that the entrance may be made to face the north. But this, in many cases, is not practicable, and it is objectionable as leading to the death of all bees that leave the hive singly on those days when the time devoted to flight should be the briefest possible. Having gone out without noticing the altered position of the doorway, they cannot on their return find it immediately, and the consequence is they fly about or wander until their powers are paralysed by the cold. Others, again, advise that the entrances should be closed with perforated zinc or gauze. This, however, is apt to be resented by the bees, for, feeling the internal air becoming oppressive and seeing the light, they crowd over the zinc or gauze, seeking an exit in such numbers as to cause many to be suffocated. Bonner made use of hot tow, and it had this advantage—that whilst it allowed fresh air to be admitted within, it excluded almost entirely the entrance of light; but so long as the rays of the sun strike directly upon a hive in a sheltered situation it is vain to hope that bees feeling the warmth will remain dormant and inactive. Consequently I look upon the plan described by Mr. Taylor as one of the best that has yet been devised for keeping bees at home when the atmosphere is chilly, or soft floury snow is on the ground. It is this: "Fix before each hive a wooden screen nailed to a post sunk in the ground, and large enough to throw the whole front into shade. This does not interfere with the coming-forth of the bees at a proper temperature . . . . . and it should be fixed a foot or two in advance, and so as to intercept the sun's rays, which in winter will be chiefly towards the west side." To this I may add that if the screen be large it will be no disadvantage, but the contrary, to have it placed 3 or 4 feet from the front of the hive. Shutting up entrances beyond what will serve to exclude the field mouse should, if possible, be avoided.—R. S.

SPURIOUS HONEY.

I TOOK no part in this controversy, like your esteemed correspondent "A DEVONSHIRE BEE-KEEPER," having little light to throw upon it, and I have no knowledge of either Mr. Pettigrew or "A LANARKSHIRE BEE-KEEPER" further than from their communications to "our Journal," but I can join "in the pleasure not unmingled with profit" with which I have perused the contributions, not of Mr. Pettigrew alone, but of both.

Mr. Pettigrew's efforts to expose the rascality of any bee-keeper selling sugar-syrup for flower honey is worthy of all praise; and believing that this substitution could and has been made, and having called attention to the same subject in this Journal two years ago, I could sympathise very much with him. Still, I quite agreed with "A MANCHESTER MAN" that Mr. Pettigrew's remarks were unfortunate in coupling his censure with the Stewarton system. From inquiries I caused to be

made at the time among some of the most extensive of the Ayrshire bee-keepers, men quite above the meanness of such adulterating practices, I was assured it was by no means practised among them—that, indeed, it would not pay; and from a somewhat lengthened experience of their system I would rather incline to think it might prove a temptation to bee-keepers working on the swarming or some other mode lacking the vast population of Stewarton stocks, by which supers in favourable seasons can be readily filled without any such extraneous aids.

That Mr. Pettigrew unfairly maligned the bee-keepers of a county where practical bee-keeping has been brought to perfection, and who turn out supers unsurpassable anywhere—materially assisted by the abundance of white clover in their old pastures, and their painstaking in moving their stocks from earlier to later districts as the season advances, and procuring swarms from localities earlier than their own—can be clearly demonstrated from the following:—Supposing they were so unprincipled as to fabricate sugar-syrup comb in the wholesale manner indicated, so that three boxes could be sent to Manchester and come under his review at one time, during a season when, from the unexampled abundance of clover honey, the finest supers were readily procurable at from 9*d.* to 1*s.* per lb.; yet this last season, from the extreme dryness of the summer, the staple flower so utterly failed to secrete its wonted nectar, that I was informed by a leading Ayrshire bee-keeper there had not been, he believed, a single completed box of clover honey in all the county. What a chance for the adulterators! Clover honey not to be had, a warm summer with their bees all idle ready to store; and how opportunely a railway opened bringing the finest Greenock crush sugar direct from the refinery to their own doors! And what do we find? After inquiring of the most extensive honey dealers in Glasgow I have had invariably the same answer—"Not offered a box of honey from Ayrshire this season." This surely requires no comment.

But how are we to get over the three supers referred to by Mr. Pettigrew, who positively asserted they were sugar syrup? "A Lanarkshire Bee-keeper," on the other hand, who seemed to have inspected them before their dispatch, was equally confident they contained no more sugar than his pen. Of this I know absolutely nothing. Would Mr. Pettigrew pardon the suggestion that possibly he may have been mistaken? seeing clover honey from Stewarton hives, gathered so rapidly as it was in such a summer as that of 1869, was of a limpid purity not unlike syrup, and likely to cause a party unfamiliar with it to make the mistake, which has frequently been made before.

To illustrate this, I have a very vivid recollection, in the days of my novitiate, of the first time I examined in a Glasgow Italian warehouse some supers of clover honey. The combs were so massive and straight-wrought, and their contents of such dazzling purity, that I came away thoroughly disgusted with my poor tops at home, of which I had been previously not a little proud, with their twisted unsealed combs irregularly studded with odd pollen-cells and small patches of brood, and all abominably discoloured over the central holes of my straw skeps. I speedily took counsel of my preceptor, a shrewd and most experienced bee-master of the old school, and exactly such as I picture in my mind's eye Mr. Pettigrew to be, and related the marvels I had witnessed. He listened quietly, unmoved at my glowing description. Had he seen them too? I asked. With a twinkle in his eye and a shrug of his shoulders, "Oh yes; yon's all sugar," was the reply I was staggered with. Not quite content with this, I subsequently made repeated excursions into Ayrshire to acquire a knowledge of the Stewarton system, purchased hives, and set to work; and after a good many years' experience it so happened that I took last season from a Stewarton stock at one lift three, and the previous season from the same colony four, 20-lb. supers, that for straightness and purity would fairly vie with the above, and the stock had not had a single tea-spoonful of sugar for the last three years, convincing me how thoroughly my old friend had been mistaken. I have been assured by most experienced judges of honey who officiate at the leading shows, that such adulteration of honeycomb is seldom to be met with, that it would not pay, and is resorted to by the merest novices to complete a box or glass, but that the difference of colour and rough crystallised appearance at once lead to detection.

Mr. Pettigrew, in No. 446, remarks, and very justly too, that "Sweetened water never becomes honey, even though twice swallowed and disgorged by bees." He may not be aware, and it may interest him to know, that seven or eight years ago the theory was advanced that sugar syrup so swallowed underwent a chemical change before being stored by the bees, so as to convert it into veritable honey; but this doctrine, though upheld by high authority, including one of the ablest pens whose contributions adorn the bee portion of the Journal, our Editors, to their credit be it mentioned, strenuously resisted.—A Renfrewshire Bee-keeper.

FOUL BROOD.

There is a Latin phrase, *Tempora mutantur et nos mutamur in illis*. I wonder whether "A Renfrewshire Bee-keeper," or myself, have changed most in our opinions on this very subject of foul brood. I have hitherto always acknowledged the courtesy of language, and general fairness of "A Renfrewshire Bee-keeper" as a controversialist on this and other bee subjects, but in the article before me I fear that he has deviated somewhat from this excellent rule. May I not express the opinion, that in taking up these articles for criticism and remark, after so long an interval of time, he has overlooked much in them which behoved him to notice, and inadvertently, perhaps, led him to reiterate charges of "unfairness," which I thought were long ago refuted and abandoned? In this way he has chosen rather to crack the nut than to taste the kernel; to look upon the casket more than its contents. May I also be permitted to make a similar observation in reference to Mr. Woodbury's reply to these articles immediately after their appearance in the Journal?

There is one remark, however, which has been so often made before, and which is again repeated, *ad nauseam*, by "A Renfrewshire Bee-keeper"—namely, that I "unfairly ignored" Mr. Woodbury's experiences as to the manner in which foul brood was introduced into his apiary. Now, I cannot see this. In combating opinions, we are not ignoring facts. In opposing the beliefs and experiences of others by counter beliefs and experiences of our own, we are not necessarily trespassing against the rules of "fairness." No. We are merely calling into question the accuracy of observation, the correctness of inference. The author of "The Handy Book of Bees," for instance, among other errors he has committed in the natural history of our little favourites, boldly asserts that bees remove eggs, and assist the queen in placing them in the cells! Also, that queens are reared from drone eggs! And, again, that the queen in setting out on her marriage tour, is pursued through the air by a host of males, probably like a fox by a pack of hounds, so that the poor queen comes to grief often, as master Reynard does, and may sometimes be found lying on the ground literally almost worried to death, by a cluster of rapacious drones! The author, for whom as a practical apiarian I entertain a high opinion, and whose "Handy Book" I have read with much pleasure, is, no doubt, perfectly sincere in his beliefs; but these, in my opinion, are not facts, but mere fancies, unsupported by evidence, and contrary to all careful observation and sound experiment. So also as to the new method of controlling the fertilisation of the queen. It is vouched for by several most respectable individuals. Details are given, and evidence is cited, but, nevertheless, and notwithstanding all this, I believe them to be in error. I reckon the asserted facts are but fancies, optical delusions it may be, or errors in observation and experiment.

Now, if this is the kind of "unfairly ignoring," to which "A Renfrewshire Bee-keeper" refers, he has not chosen the most appropriate words to characterise what I hold everyone in this land of free thought and utterance is privileged to exercise—viz., the unfettered expression of opinions on all subjects, not even excepting this large question in the eyes of apiarians, the origin of foul brood.

As to the subject foul brood itself, how stands it? Whence its origin? How its cure? Have apiarian authors and writers agreed as to the first? Is there a *concensus* of opinion as to the latter? I trow not. Is there not rather a Babel of discord and contrariety? The great aim of some is to discover a remedy for the evil; mine has been to ascertain its origin, prevention being in my estimation better than cure. I ascribed it, according to my experience, to chill, neglect of the brood, and other cognate influences; and I have conceded that brood stewed alive by heat may be as disastrous, for aught I knew, to a colony of bees, as brood starved by neglect and cold. The great question is, Have like evil results followed both extremes? It is not a paradox that dissimilar causes may produce similar results. "A Renfrewshire Bee-keeper" believes that overheating originates foul brood. I believe it frequently may. I also believe that from very opposite causes, such as I have named, the same results also frequently follow.

When I first promulgated these views I wrote from personal experience only. I knew nothing of Dzierzon, Baron von Berlepsch, and Quinby's experiences in foul brood. Had I done so I might have dwelt less upon remedial processes, which at best, I admit, are unsatisfactory, and "A Renfrewshire Bee-keeper" knows that I even then declined to undertake the cure of a hive he was so kind as to proffer me.

Let me ask "A Renfrewshire Bee-keeper" to look those articles over again upon which he has bestowed some criticism, and see the quotations I make from various authors and writers, more especially from Dr. Preuss, how similar his views are to my own in respect to the bad effects of unhatched, neglected, or chilled brood, not being removed from any hive, furnishing by their presence "a particularly favourable soil" for the introduction of fungi, and consequently, according to his theory, of foul brood. Why should a critic so fair as "A Renfrewshire Bee-keeper" ignore all this evidence I put

before him and others, so as not to devote one single word to its consideration? He will see I do not now stand alone in my opinions, nor can they any longer be called peculiar. They are shared more or less by several of the most scientific writers on the subject. I believe foul brood may originate from other causes, as I have already stated in the articles referred to; and on the assumption that Dr. Preuss's theory is a correct one, I could reconcile, I think, as already expressed, what appear to be conflicting propositions, more especially as to the manner in which foul brood often originates, and, once produced, how it is propagated.

"A RENFREWSHIRE BEE-KEEPER," I should notice, is unwilling to concede the point that there is any analogy between brood killed by heat and brood killed by cold, and ascribes foul brood in the former case, not to the presence of dead and unremoved larvæ, but to the fermenting of the honey, "induced, doubtless, by the effects of the heat and the condensed moisture mixing with the unsealed honey, causing it to ferment, and acting in a deleterious manner on the larvæ when fed with it." This is, I think, a very questionable surmise, and for my part I can see no ground whatever for such an idea.

I conclude this New Year's communication by cordially wishing "A RENFREWSHIRE BEE-KEEPER," and all my apiarian brethren who interchange opinions in our especial corner of the Journal, many happy returns of the season, not forgetting our respected and worthy Editors, by whose kind indulgence I am permitted to say so much.—J. LOWE.

[Want of space has obliged us to omit some paragraphs.—EDS.]

OUR LETTER BOX.

BOOKS (*H. C.*).—The book you mention is 3*s.* 6*d.* uncoloured, and 7*s.* 6*d.* coloured. Any bookseller can obtain it for you.

POULTRY AND CANARY SHOWS.—We have received the lists of prizes awarded at Skelton and some other shows, but we do not publish them, concluding that they are only of local interest, as the committees did not advertise them.

GOLD-SPANGLED HAMBURGHS (*Gallus*).—We cannot find space for a detail of "the full points of both cock and hen." If you enclose seven postage stamps with your address we will send you, post free, "Poultry Book for the Many." It contains the points of all the varieties. Eaton's book is out of print. The late Mr. Brent edited "The Pigeon Book." You can have it post free for twenty postage stamps.

EXHIBITING TOGETHER DIFFERENTLY-AGED FOWLS (*Amateur*).—Where there is no restriction, and no rule to the contrary, birds of different ages may be shown together. When the classes are defined and separated, it must not be, as it is at least a dishonourable proceeding. In making up a pen of different ages you must be careful that all the birds match in size and appearance. Although nothing is more difficult than to tell the exact ages of fowls after they have reached maturity (say ten months), yet there is often a perceptible difference between a pullet and a hen, and if the judges are hard run, they are glad of anything that will justify them in striking out a pen.

BRAHMA CHICKENS CROOKED-BREASTED (*W. J.*).—The crooked breast-bone does not make the bird delicate. We should be disposed to attribute the defect to their having perched too early. Brahmas are birds of quick growth, and are lanky when young. If put on the perch too soon their legs are not strong enough to bear the weight of their bodies by grasping the perch with their toes, and, consequently, they rest their breasts upon it. As the breast-bone is then little better than a cartilage, it takes the impress of the perch. We do not for a moment believe you will find it hereditary, any more than you would expect a child to have a contracted form because its mother when young laced too tightly. They will soon lay, but, as a rule, birds that are meant to do so before Christmas should be hatched either late in April or very early in May. We breed many fowls, and are, unfortunately, overrun with rats, but we do not think our chickens in danger when they are large enough to remain on the perch when put there.

SICK FOWLS (*Subscriber*).—Give No. 1 Baily's pills, and add to them one pill daily of camphor the size of a garden pea. Give No. 2 Baily's pills, and follow them, when the bird is convalescent, with meals of bread and ale three times per day. Give No. 3 castor oil, a table-spoonful every day, till the blood and yellow matter have ceased, and the evacuations are brown and white. You must watch that she be not too much reduced. If she is, give her bread and ale. Case No. 3 is the worst.

HEATING A BARN FOR FOWLS (*R. S.*).—We are not friendly to heat derived from a flue for poultry. It has a tendency to enervate them. They no longer wander abroad in search of food, but finding it cold out of the house they return to it, and squat about in it all day. The proper way to make fowls lay, and to keep them warm is to feed them well. All they require at night in the way of warmth, is to be lodged in a dry place thoroughly protected from draught. If you keep as many as a thousand, or even five hundred fowls, you will do better by dividing them in several houses rather than putting them all in one. It is far healthier. If you intend to make a profit from the sale of eggs, you must be careful to get a supply in the winter when they are most saleable. For this you will have to keep pullets hatched in April and May. We think you will do as well with Brahmas and Cochins as with any breed. They are very strong and healthy. That is what you require where many are kept together.

DORKING COCKERELS (*Gilbert*).—The difference in a Grey or a Silver-Grey Dorking cock is, that in the first there is no decided plumage, but in the second the breast and tail must be purely black, one white spot would disqualify. The hackle and saddle must also be white instead of straw-coloured.

MANCHESTER SHOW.—"In consequence of the address of this Show and that of the exhibitor being on the same side of the label, my five pens of Spanish which were entered for it, came to me from a run in Cheshire, where I keep them, instead of being delivered in Manchester. I think it would be better in future that the addresses should be on different sides, as at most shows; as it is very annoying to have one's pens empty when the birds look like winning.—H. YARDLEY."

CANARIES STOLEN AT IPSWICH (*J. N. H.*).—We do not think that more notice would avail. Committees should have more watchers.

CRYSTAL PALACE SHOW (*Oxoniensis*).—We believe before you see this you will have received the amount.

RING DOVES (*R. L.*).—We have frequently known them kept in greenhouses all the year, and never heard of their suffering from the humid atmosphere.

HYPO-SULPHITE OF SODA.—This was erroneously printed hypo-sulphate on page 525.

POINTER DISEASED (*J. P. C.*).—The convulsive jerking and twitching of the neck and chest indicate chorea. Meyrick, in his excellent little volume on dogs, gives the following directions:—"The general health and diet must first be attended to. A few doses of castor oil are usually necessary; accompanied by blue pill (dose five grains), if the liver is deranged, as shown by the clay colour of the fæces. The food should be given twice a-day, and should consist principally of vegetables, potatoes, oatmeal porridge, &c. When a better state of health is established, it will be time to give medicines to remove the disease itself. For this purpose it is best to begin with liquor arsenicalis, mixing two drops with each meal, so that the dog will take four drops in the day. The quantity must be gradually and cautiously increased by one drop daily, and so increased for a week. The same quantity must then be continued, and will often have to be given regularly every day for a month before a perfect cure is effected. As soon as the dog rejects his food, is bloodshot in the eyes, or has a running at the nose, it is necessary to stop the medicine, at least for a time. If it has had no perceptible effect in subduing the convulsive jerkings of the muscles, it would be advisable to try, night and morning, a ball containing sulphate of zinc, two grains; powdered gentian, ten grains; syrup of ginger, qu. suff."

WATERPROOFING (*J. D. L.*).—The composition varies according to the object to be attained; state for what you need it.

METEOROLOGICAL OBSERVATIONS

In the Suburbs of London for the week ending December 27th.

COVENT GARDEN MARKET.—JANUARY 4.

BUSINESS transactions are limited to supplying the daily wants, and Saturday is now the only market day on which we are likely to get what we require. Hothouse produce, however, is sufficient for present purposes, and does not meet with the demand usually experienced at this season. Potatoes are amply supplied. Trade is dull.

POULTRY MARKET.—JANUARY 4.

THE Christmas arrivals from abroad are not yet quite disposed of. The excitement of Christmas always gives way to positive collapse, and there is no trade worth quoting. Another thing to be noted is, that frost will often stimulate trade, but snow always destroys it and hinders all demand. It also interferes much with supply. We make quotations to the best of our ability.

From observations taken near London during forty-three years, the average day temperature of the week is 42.3°, and its night temperature 29.8°. The greatest heat was 54°, on the 12th, 1852; and the lowest cold 3°, on the 13th, 1867. The greatest fall of rain was 0.86 inch.

GARDENERS AND GARDENING.

THOUGH this is a subject to which I have given much thought, it is one which I approach with diffidence, for I by no means pretend to the possession in person of all the qualifications to which I shall allude, but it is from a desire to draw attention to the subject, more especially the attention of youthful aspirants, that these notes are written.

It is an acknowledged fact that second and third-rate gardeners, or, to speak more correctly, men who will give their services at a comparatively low rate of remuneration, are much more in request than first-class men. This may easily be accounted for from the fact that small gardens are more numerous than large gardens; and although, as a rule, the pay is low in small places, there are always plenty of men of moderate capacity on the out-look for such vacancies, many of which are not unfrequently filled by persons professing to be able to do things quite beyond their abilities.

Another reason worthy of serious consideration is, that the majority of men trained in large, or even in moderate-sized establishments look down with contempt on small gardens and those who have charge of them, and yet I have known many a small garden so skilfully managed, and everything in it so thoroughly well done, that it quite surpassed its larger neighbours. To have the charge of a large garden is a laudable ambition, but when the object of this desire is attained it does not always bring with it the expected gratification, for many large places have serious drawbacks, such as deficiency of labour power, little manure to renovate the soil, a poor supply of water, and other hindrances to success; so that a man, however zealous he may be, may spend his strength in vain efforts to overcome such formidable obstacles.

"Whatever is worth doing at all, is worth doing well," is a maxim which gardeners above all other men should apply to their work, and, therefore, before taking charge of a garden, it is very important to ascertain if the assistance and working materials are in proportion to the size of the place, and if not, it is much wiser not to run the risk of failure by entering upon an engagement which is likely to prove unsatisfactory. When a man deliberately takes charge of a garden it should be with the firm resolve to strive for success to the utmost of his abilities. Gardening is an arduous pursuit, fraught with many difficulties which only the really earnest man can hope to surmount; it has no royal road to success, but demands unceasing diligence, foresight, and care. To the man who likes it for itself, and is thoroughly devoted to it, success is the best reward, and whether the garden under his hands be large or small will be not so important a consideration as that every plant and crop may be brought as near to perfection as possible.

Let us now consider what are the requisite qualifications of a good gardener. As I have before said, he should be thoroughly devoted to his calling, earnest, diligent, energetic, and thoughtful; he should not be content to take things for granted, but should strive to search into cause and effect for himself; not given overmuch to experiments, and yet ever seeking for reasonable improvements with a view to the advantage of himself and his fellow-men; for he should be altogether free from that narrowmindedness which seeks to withhold knowledge, but should be ever ready to impart or receive instruction. In controlling his assistants and labourers he should, by a judicious exercise of firmness and kindness, see that his rules are strictly acted up to and his orders obeyed to the letter. Harsh language should never be resorted to; it is degrading both to master and man. Amongst a number of men there are certain to be a variety of dispositions and character—some will be cringing or officious, others dilatory and careless, while a third party will quietly obey orders without any display of overmuch zeal, and it is this latter class who generally prove to be the best men. But, whatever may be the dispositions of the men, a quiet, firm rule, tempered with kindness, is by far the best method of controlling them.

In his intercourse with his employers and all others of a higher station than himself there can be no necessity for cringing or an excessive display of humility; all due respect should, of course, be paid, and every wish and order carefully attended to. A man can be respectful without cringing, and quietly study the wishes of his employers without officiousness.

In the management of a garden, close attention should be given to the smallest details—nothing should be overlooked or done in a slovenly manner; there should be no neglected corners, weedy paths, nor dirty houses; but cleanliness, order, and exquisite neatness should everywhere prevail; even the very heaps of soil and rubbish should possess a trim appearance. Great care, too, should be taken to name each plant correctly with neat labels and plain writing, without any display of flourishes or fanciful colouring. A gardener ought, certainly, to be acquainted with the nomenclature of every plant under his care, but too little attention is given to this in private gardens; even when plants appear to be carefully labelled, the spelling of the names is often very faulty, and that, too, in many of our leading gardens. While devoting proper attention to this important point all pedantic display should be avoided. The mouthing of scientific names, if profuse, becomes ridiculous.

The difficulties which beset the gardener in the pursuit of his calling are undoubtedly very numerous; but then, if he be a man of energy and resource, every trial acts as an incentive to increased exertion. The experience gained in all such struggles is of the highest value, and when once the habit of boldly facing a difficulty is formed, it becomes part of one's nature.

In thinking over a gardener's difficulties, his position as a servant naturally comes to mind. It is to be feared that there is a lamentable spirit of mistrust and antagonism existing between many gardeners and their employers. This is very much to be deplored, for its existence must seriously affect the enjoyment of the one in his garden,

and the efforts of the other in his care and culture of the plants entrusted to him. A very common subject of complaint is, that in the garden the gardener assumes to be "Lord paramount," entirely ignoring all knowledge of his business in those who employ him. It is to be feared that this is not unfrequently the case, but it surely ought not to be so; common courtesy, to say nothing of duty, should teach one to receive the commands of those whom one serves with the greatest respect, and if possible to carry them out to the letter; if this cannot be done, a respectful remonstrance should suffice.

Very much has been written concerning the trials and difficulties which beset a gardener in the pursuit of his calling, but it is very rarely indeed that anything is said about the privileges and enjoyments which are his. I will venture to step out of this beaten path, and forget for a moment the anxieties of frosty nights, unkindly seasons, and all the ills which endanger our tender crops and delicate exotics, and will glance at the "bright side of things." Surrounded by Nature's choicest gems in an endless variety of form and colour, each season presenting its peculiar attractions—the freshness of spring, the richer developments of summer, the fulness and abundance of autumn, and the soberness of winter, all are peculiarly his to enjoy. Then there are the multitude of interesting objects constantly claiming his attention, and if many of them do try his skill to the utmost, why the greater the exertion the greater the enjoyment of the success which generally follows. There can be no complaint of sameness, but rather of repletion, for novelties of all kinds are constantly pouring in upon us, exciting much interest, and affording much amusement in the comparison and trial of their merits. And so I might go on, and enumerate all the brightness and beauty which we enjoy, but I will rest contented with observing that we may all be happier, better men if we go through life without giving undue weight to its cares and sorrows, but rather striving to realise its blessings, of which many of us possess a much greater share than we are aware of until they are taken away.—Edward Luckhurst, *Old Lands, Buxted, Sussex.*

BEDDING GERANIUMS.

Though I am afraid some of your readers will be tired of the subject of bedding Geraniums, yet there are others who may be interested in some notes I made last year, at the establishments of three of the principal raisers of Zonal Geraniums—namely, at Mr. Pearson's, of Chilwell; Mr. W. Paul's, of Waltham Cross; and Mr. Laing's (of the firm of Downie, Laird, and Laing), at Stanstead Park. I name them in the order in which I visited them.

Chilwell Nurseries have been so well described by your able correspondent Mr. Luckhurst, that I shall not say much with respect to the nurseries themselves, but merely confirm what Mr. Luckhurst says with regard to the thorough way in which Mr. Pearson carries out all he does there. I consider Mr. Pearson's glass ranges models of what glass houses ought to be, and I agree with him in what he said in his article on horticultural fallacies, that it is very astonishing to see the old moveable sash-lights and slides, with heavy rafters, still being built.

My first visit this year at Chilwell was on the 24th of June, when, owing to the exceeding drought, the Geraniums had not sufficiently recovered their planting-out. Among the seedlings sent out by Mr. Pearson in 1870, I consider the best to be William Thompson (an improvement on Bayard), Thomas Speed, and Douglas Pearson (also an improvement on Bayard). Of these three Thomas Speed is the darkest, a crimson; and Douglas Pearson the brightest, a scarlet crimson. Duke of Portland and Duke of Devonshire are more of the true Zonal, and likely to be very good for pot culture. E. J. Lowe is a very fine rose pink, with large pip and truss, which may prove too strong for bedding. Lawrence Heywood is a peculiar shade when bedded, lilac rose, with a fine head of flowers, though rather weak in the flower stalk—in fact, I think the chief fault of the Geraniums sent out by Mr. Pearson in 1870 is, that the trusses are too large for the stalks, having too much of the Black Dwarf strain. This fault is remedied in seedlings of 1870, which will most probably be sent out in 1872, as he has several very valuable strains from Violet Hill, one of which (he has named it Miss Rose Peach), will, if it turn out as well as it promises, give us one of the desiderata, a dwarf pink bedder. Another, a lilac seedling, called Mrs. Reynolds Hole, is also of great promise. He has also several fine seedlings of 1870, of the Bayard strain, with stiffer flower stalks; but of these I hope to give a further account next summer, and I hope, as the Royal Horticultural Show is so near Nottingham, that we shall see some of his seedlings there. It was still more difficult to test the 1869 seedlings, the best of which had been saved and worked-up for stock, and the dryness of the weather had prevented them showing to their best.

My second visit to Chilwell was on the 5th of August, when I looked through several hundreds, if not thousands, of seedlings. Several very good pinks and lilacs of the dwarf section had bloomed since I had been there before. Many of them were put aside for future trial, and almost any would be valuable as bedders, the great difficulty being to select the best.

The Tricolors had much improved, and one called Mr. W. Sanday (after an old and valued friend of mine, an eminent champion with Leicester sheep), is one of the most distinct and striking among the Tricolors, as a bedder, that I have seen as yet. Other very good ones were Mrs. Edge and Edith Pearson. It was still difficult to judge of the 1869 seedlings owing to the very trying summer, but where there are so many seedlings to select from, and with the care which Mr. Pearson personally gives to the selection, the public may safely try any Geraniums, especially Zonal Nosegays, sent out from Chilwell.

The next nursery I visited in pursuit of new Geraniums was Mr. W. Paul's, at Waltham Cross. Having gone up to London to assist at the inauguration of the Metropolitan Floral Show, I went on September 7th to Waltham. I was very unlucky in my day; it began to pour just as I was starting, and owing to the causeway in the Strand being all pulled up for repairs, I missed the train at Bishopsgate Street by a few seconds, the door of the station being closed as I was paying the cabman, and I had to wait for nearly two hours. When I got to Waltham it still kept on a pouring rain, and I had to see the Geraniums under an umbrella. It was, therefore, a great trial to them, especially as there had been heavy rain several times during the ten days previous, but the Geraniums bore the trial well. Among the best were:—Bonfire, a fine scarlet crimson, large truss, dwarf habit, with good footstalk, apparently a very free bloomer, and a very desirable sort. Robinson Crusoe, magenta crimson, with a flame on two top petals, a fine flower to look close at, and good for pot culture. Titan, fine rose, but too strong a grower to please me for bedding. Waltham Nosegay, well known, much like Waltham Seedling, but with a plainer leaf; and while referring to Waltham Seedling I cannot refrain from mentioning one of its most valuable qualities which is too often lost sight of, the continuity of blooming. I have two letters from friends to whom I recommended it, saying it had lasted longer with them than any other sort, and I have heard since from Mr. Paul, that he has had the same testimony from Mr. Moore and Mr. Gibson. The young ladies of Beulah Cottage condemned it for its smallness of truss. I can only say I have measured the trusses from 4 to 5 inches across, and though I quite agree with the young ladies that one of the greatest merits in a bedding Geranium is size of truss, still freedom and constancy of bloom, with a good habit of footstalk to show the bloom to advantage and stand weather, are more valuable still, and in this Waltham Seedling and Violet Hill are as yet unbeaten.

But to return. The next marked in my note-book was Rainbow, something of the colour of the old Sutton's Perfection, but a Nosegay; then Vesta, a dwarf dark scarlet, very favourably reported on in the Chiswick trials (first-class certificate). Next came Comet, a fine orange scarlet, not quite orange enough, but of a very striking colour and fine habit of growth, dwarf and compact. A fine pure orange is still wanted. Evening Star, a peculiar shade of soft rose, also dwarf. Boadicea, rather like Robinson Crusoe, but not so dark in colour; likely to come out well in autumn. Cyrus, an improvement on Glory of Waltham, more dwarf and free-blooming. Lilac Rival, of which I cannot recall the habit. Dante and Penelope, both very good rose pinks, adapted for pot culture, but also good for stronger beds or ribbon borders. Claude Lorraine, another fine shade of magenta, likely to prove a good bedder. I had not time to go through Mr. Paul's seedlings as I should have liked, as I was due at Sawbridgeworth at 3 20 to see Mr. Rivers's nurseries, and I had not time either to take special notes of the Tricolors or white-edged varieties, of which Mr. Paul has so good examples in Avalanche and Waltham Bride.

The next day I went to Stanstead Park to see Mr. Laing's nurseries, and was more favoured in my weather. I especially went to see his seedling Bronzes, but there were Nosegay seedlings as good as the Bronzes. Several of them I have already described, and they are known to many of your readers.

Lady Kirkland, which I had only judged before from a single plant in my possession, which I had thought most promising, more than verified what I expected of it. The trusses are very fine, and I especially remarked the whole bed had not a seed pod on it, and Mr. Laing said it hardly ever showed one during the exceedingly hot weather. In colour it is something like Duchess of Sutherland. Lady Hawley, another sent out by Mr. Laing this year, was also very good, fine scarlet, a crimson shade, not orange, dwarf, and free-blooming. Sunshine and Sunlight, also good. They have bloomed exceedingly well with me in small pots this winter, cuttings struck in August being in good bloom now. Of the Zonal Nosegay seedlings not yet sent out were Star of Fire, scarlet crimson, very vivid colour, free-blooming and spreading habit, sure to be a good bedder; and Phœbe, orange cerise, of nearly the same habit as Star of Fire; Moor of Venice, pure crimson, fine colour and good habit; George Peabody, somewhat similar in colour but more scarlet, also not seeding, in habit putting me much in mind of Mr. Pearson's strain. Mr. Laing had several of the French seedlings planted out, but all seemed to me to be wanting in firmness of petal.

But the greatest acquisition among new seedlings was a pink Zonal Nosegay called Pink Queen, a basket of which Mr. Laing had shown at the Metropolitan Floral Show at the Crystal Palace, and which I here saw planted out. In colour it is more like Helen Lindsay than anything else, but it is of a finer tint, and has a large truss instead of a small one, as Helen Lindsay has; to judge from the way small plants of it bloom it is likely to prove a most valuable bedder, Mr. Pearson's seedling Miss Rose Peach being the only rival to it I have yet seen.

To turn to the Bronze and Gold section. There were many fine unnamed seedlings planted out, though as bedders none, I think, surpass two Mr. Laing has already sent out—Impératrice Eugénie and Crown Prince. The first, Impératrice Eugénie, is the most brilliant in point of colouring of any Geranium I have yet seen bedded in mass; and next to it comes Crown Prince with a stronger habit, though it will never be coarse, as it has so little green in it. Mr. Laing had most of his best seedlings at the Crystal Palace, but as they were still unnamed it is not possible to particularise them. In my opinion, however, in aiming after form and breadth of zone he has rather lost colour, some of the zones in the Bronzes being so broad as to leave very little centre or margin; but for those who like very circular flat leaves and dark-coloured zones of the Black Knight type there are some very fine sorts. Next to Impératrice Eugénie I class Brilliancy in point of colouring; then come Mrs. Alan Loundes, Harrison Weir, Princess of Wales, and Charming. Mrs. Lewis Lloyd, a fine gold colour with only a narrow zone of red, makes a very striking bed. One peculiarity of this type of Bronze is, as I have before remarked, that they do not turn green as they die off, but a lighter colour, the zones sometimes crimson, and the effect in a bed is very remarkable; in fact, the colour of a bed of Impératrice Eugénie is more gold and red than bronze. They require warm treatment in winter and good food in summer to bring out their colours, and they well repay all care.

I would again repeat what I have said before: If people wish to have Geraniums in good order when planting, and to make a garden gay early, never let them be too cold in winter. Hardy though they are, a cold damp treatment is the worst they can have. Keep them growing, with plenty of light and air, and a temperature never under 45° nor above 60°, and a garden will be gay a month or six weeks sooner than if they had been what persons call hardened in the winter, which is really no hardening, but a stagnation of life from which the plants recover with difficulty. I have now all my cuttings, which were not taken from the beds till the middle of September, potted off, and they are more forward than if they had been struck in the open ground in August and then kept in cold frames and pits, and they will be still more forward by bedding-out time.—C. P. Peach.

The Advantages of Bottom Heat on a Large Scale.—One of the most curious phenomena in connection with coal mining is exhibited at the Bank Colliery, near Rotherham, the property of Earl Fitzwilliam. This pit caught fire one hundred years ago, and all the efforts of the workmen at the time, and subsequently, have been quite ineffectual to extinguish it. A short time ago it was ascertained that the flames were approaching the bottom of the shaft, and it was then resolved, if possible, to stay their progress, so that they might not extend to other parts of the workings. At length the superintendent of the collieries, Mr. T. Cooper, conceived the idea of building a wall to shut in the fire, and in order to ascertain the best site for this wall, several of the officials crept on their hands and knees, through the dense stifling smoke, as far as possible into the workings. Their efforts were successful, and a wall is now completed nearly 1000 yards in length, and varying from 9 inches to 5 feet in thickness. At distances varying from 30 to 50 yards metal pipes have been inserted in this wall, which are securely plugged at the end, so that at any time, by removing the pluge, the state of the air on the side of the fire, and even the position of the fire itself, can be ascertained. So intense is the heat arising from this fire that people possessing gardens above the colliery declare that the growth of plants is materially affected, and that they are enabled to obtain two and three crops every year.

GROWING EARLY POTATOES.

Any method by which the easy culture of early Potatoes can be accomplished is sure to be of service to those on whom there is a great demand for them early in the spring, and to that end the following paper aims. A method usually adopted for obtaining early Potatoes is to prepare a bed of fermenting materials in a pit, or to form one on which frames are laid, and after the soil within becomes warm, to plant the sets at once without any careful preparation. As a matter of course the Potato is soon at work, the heat from the bed forcing it rapidly, and at a season when much air-giving is seldom admissible; the consequence is too frequently an abundance of haulm, with a light crop of tubers.

I invariably obtain good crops of early Potatoes by potting some in 8-inch pots the first week in January, using a handful of fresh horse droppings over the crock, and light fresh soil for potting in. Having the set disbudded to one shoot, and giving the Potato a cut about an inch in length and depth at its base, I place the set low down in the pot. The pots can be stored in any structure affording a gentle warmth until the leaves break through the soil. By this time a slight hotbed is ready for them, the depth of fermenting materials being about 2 feet; on this is laid to the depth of 6 inches soil, which should be rough and light. On it the pots are placed for about a week or ten days, admitting air in abundance at all favourable opportunities. When the stems are 4 inches high, the plants are turned out of the pots and planted at distances of 18 inches by 1 foot, opening up the soil sufficiently to admit the ball to half its depth. The soil removed is then carefully worked round each plant, scarcely covering the roots. When the growth is 8 inches high, warm soil is worked in between the rows up to 2 inches above the original ball of earth, leaving the whole surface flattened. The plants seldom require water, the moisture arising from the bed being nearly sufficient for them. Give air at all favourable opportunities, covering well up on cold nights, but having constantly a slight amount of air. By the time the foliage commences to curl the Potatoes will be rapidly forming, after which scarcely any water should be given, otherwise it will materially interfere with their flavour.

The best variety for frame work, if steadily grown, is Myatt's Prolific, the tubers coming out very even in size, about 2 inches under the surface of the soil, and passing beyond the original ball of soil some inches.

I also find it serviceable to pot in 10-inch pots a quantity of the Cockney, an early dwarf-topped Potato, well adapted for pots, the tubers forming close at home, and being of good size. This is done in the first week of April, placing them in any unheated house or frame, and when fear of frost is past, a trench is then opened on a south border, in which they are placed, still remaining in the pots, over and between which the loose soil is carefully worked, leaving the mound of soil about 4 inches above the surrounding level. By this means I obtain an excellent lot of young Potatoes a fortnight sooner than from the open borders.—T. C. Sage.

GROWING DWARF POINSETTIAS.

When the Rev. C. P. Peach is trying his experiments with the dwarfing of Poinsettia pulcherrima, as I see he intends to do next year, may I ask him to try the plan of growing four plants in a pot, and flowering them as dwarfs? If he succeeds, of which I have no doubt, I think he will be highly pleased. I have not yet had the opportunity to do more than try two or three pots, and these gave me satisfaction. They were so very handsome and effective when placed in a row with the Single White Roman Hyacinth, and edged with small plants of Sela-

ginella denticulata, that I have decided to grow more of them when convenient.

My plan was to take the points of the medium-sized blooming shoots, and make them into cuttings about 4 inches long, taking off the bottom leaf only; to place each cutting in a very small pot, say a 72, or 2-inch pot; and to strike them in a brisk bottom heat and a moist, close atmosphere. Afterwards I put four of these cuttings in a 6-inch pot; the tallest in the centre, potting it rather higher than the others, and three round the sides. Place the latter slantingly and equidistant. I used a rich turfy loam, a handful of rotten cow manure, and sand. I kept them in close quarters until established, and then allowed them more light and moderate air. They cannot grow tall with such moderate-rooting space, but instead of that the nourishment the plants take from the soil will not only give the foliage a good colour, but will develope as fine a lot of floral leaves as can well be wished for, and the pot and plants will not, perhaps, exceed I foot high. The cuttings, I think, should be selected just as the shoot has ceased growing, and is about to form its tiny floral bracts.—T. Record.

GROUND VINERIES.

I have read much and heard much for and against ground vineries, and one Journal went so far as to say that they were unworthy the attention of gardeners, excepting for the growth of vegetables in winter, but they might do for amateurs. Even the inventor a week or so ago, in writing to "our Journal," said that he did not believe in them. However, being very fond of Grapes, and, moreover, being an amateur fruit-grower, I thought I would try some of them three or four years ago. So I wrote to Mr. Rivett to send me half a dozen of his pattern of ground vinery. On receiving them I saw it would be an improvement to do away with the groove for the glass to rest in, instead of which I made it to lap, and fixed with iron hooks, by which means I also got rid of the putty. I also strengthened the ends with a light iron cross-bar, and supported the ridge woodwork by bracing it to the lower wood on each side with a light iron bar. This prevented warping, which otherwise was apt to take place, and then the glass fell out. Instead of slates I paved the bottom with tiles, which I thought would hold both heat and moisture. To each Vine I allowed a growth of 21 feet—that is, three 7-feet lengths of lights.

The sorts I have planted are Black Muscat of Alexandria or Muscat Hamburgh, Foster's White Seedling, Lady Downe's, Frankenthal, Black Hamburgh, Black Hamburgh (Morris's variety), Early Golden Frontignan, General della Marmora, Fintindo, La Ville de Bruxelles, Golden Champion, Trentham Black, and a seedling of my own. Some of the Vines have fruited, others not yet, but I will give my notes of those that have.

Early Golden Frontignan bears well, and was ripe and of excellent flavour in the first week of September, both in 1869 and 1870.

Foster's White Seedling. This is a fine Grape, and succeeds remarkably well in a ground vinery. It was ripe in the middle of September.

Trentham Black did not set well in 1869, but set well in 1870. In colour it is jet black. Its flavour was all that could be desired. It was ripe in the last week of September.

General della Marmora is a free bearer, but I do not think much of the flavour. It is poor in quality, at least with me. This I shall dig up or graft.

Fintindo, a black Grape, loose in the bunch, and which does not require thinning, or at most very little. It is smaller in the berry than the Black Hamburgh, and not so good.

Frankenthal and Black Hamburgh both did remarkably well, were fine in colour and flavour, and were ripe in the last week of September and the first week of October.

Black Muscat of Alexandria was large in bunch and good in colour, and delicious.

Lady Downe's became black at the beginning of October, and was cut ripe on the 4th of November. A very free bearer.

Morris's Black Hamburgh I bought as earlier than the Black Hamburgh. I have not found it so, nor to my thinking is it so good in other respects as that variety.

The rest of my Vines I have not allowed to bear yet. As far as I have gone I deem my ground vineries a great success, as they supply me with excellent Grapes more than two months in the year with comparatively little trouble. Many of my friends, after seeing the Vines and tasting the produce, have taken the measurement of the frames and had some made, and are now growing for themselves. I do not pretend to say that the growth is equal to the fruit grown in my heated vinery, but I aver the Grapes are good and rich in flavour, equal to, nay better, in quality than many that I have seen grown in cool houses; and I would say to my brother amateurs, Try one Vine, such as the Trentham Black or the Frankenthal, and if you succeed as well as I have done, I think you will not regret the experiment. One word more, Do not have the glass less than 21-oz., and if the weather is very hot whiten the glass on the side next the sun.—Harrison Weir, *Weirleigh, Kent.*

CYCLAMEN CULTURE.

Before recording my experience on Cyclamen culture I wish to give this warning—with proper attention it is one of the most easy plants to cultivate, but without that it is one of the most difficult. I can assure Mr. W. Scott he can not only have good blooming plants in ten months, but in eight months useful ones with from two to ten dozen blooms, and I believe for general purposes from October till May they are not equalled, especially for London rooms.

For exhibition purposes, I think as a rule they should be shown in collections independently of size of pots, taking the quality of flower and foliage into consideration as the colours are so various, and perhaps in several collections of six or twelve they may be nearly all equal but different in colour.

I think in time a good Cyclamen will equal what our best Fuchsias are now in shape and substance of petal; good distinct-based flowers—that is my standard of excellence.

To have good plants in eight or ten months sow the seed any time after January, allowing eight or ten months according as the plants are wanted to bloom; 5-inch pots or pans will do. Sow about 1 inch apart in a gentle bottom heat. When the plants are up keep them as near the glass as possible, giving air gradually; and after this time they should have all the air possible, dependant upon the external temperature, and night and day during the summer months. As soon as they have made three or four leaves pot off the plants singly in small 60-sized pots, reshifting, as the roots find their way to the outsides of the pots, to large 60's, 5-inch, and 6-inch pots, returning them to the bottom heat, as they are very susceptible of any check, which will keep them on the standstill for a month or six weeks. The soil should be either warmed or the pots raised from the bottom heat two or three days before shifting. I do not recommend planting two or three plants in a pot, nor planting them out.

A frame is the best place in which to grow them during the summer months, shading at all times from strong sunshine; and as a good show of bloom entirely depends upon clean healthy foliage, the plants should be syringed at least twice a-day to preserve cleanliness, and to save the foliage from red spider, which appears to be their chief enemy.

Not later than September plants should be removed from the frames to a stage or shelf in the greenhouse or conservatory, as after that time they are subject to damp, maintaining just enough fire heat to expel frost and damp, and giving plenty of air without cold currents. If they are kept in a damp, close atmosphere whilst in bloom during the winter months, anyone can have spotted varieties to his heart's content, but such I consider a disfigurement.

After the blooming season place the plants in a cool pit or greenhouse, and gradually withhold water, but never allow them to become dust dry. After they have lost all or the greater part of the leaves, shake them out, repot, and return them to a cold frame, sprinkling twice a-day overhead, and watering at the root very cautiously at first, increasing the supply as the foliage increases. Return them to a stage in the greenhouse at the end of September. In two or three years good specimen plants can be had from 18 inches to 2 feet in diameter, with corms of from 4 to 6 inches.

The amateur may rest assured Cyclamens can be grown quite as well without bottom heat as with it. Sow the seed in October instead of in spring, place the pots on a shelf in a greenhouse near the glass, and grow the plants in a cold frame during the hot summer months.

I find the best compost is one-half good fibrous loam, and one-half leaf mould and well-rotted hotbed manure. Avoid cow dung, as it contains so many grubs, and should any be missed in the potting, they will completely destroy the plant, commencing with the roots and finishing at the corm.

A few words about the ten-months collection of plants exhibited at South Kensington by Mr. Clarke, of Twickenham,

well-known as one of the largest, most successful, and scarcely-equalled forced Strawberry-grower for maket. He forces some thousands of plants, and when in full work the fruit is a sight not seen every day, and probably he is able to gather from 50 lbs. to a hundredweight several times a-week. He consequently requires a large area of glass in frames and houses, and they are of the best form I have seen for the purpose. The Strawberries are first started in frames in bottom heat, and drafted to the houses as wanted. The Cyclamens then succeed them in the frames, and are grown in a gentle bottom heat during the summer, and removed to the houses in September, the Strawberries again following them for the winter. It must be understood his collection of Cyclamens was exhibited as a collection of about eighty or a hundred plants for quality and variety of colour, all in 48-pots, with from five to ten dozen blooms. Mr. Clarke's houses are now all filled with them, their number amounting to some thousands, all for market, in different stages of bloom, and, taking the whole as a lot of ten-months plants, I think they are not to be equalled. The plants in the early house, which is about 120 feet long by 12 wide, are now in bloom, and a sight worth going miles to see.—George Edgerton, *Strawberry Hill.*

[Mr. Edgerton sent us some fine specimens. Some of the flowers were semi-double.—Eds.]

RED AND WHITE EXHIBITION POTATOES.

Really it does seem like a reverse of history when a "Raleigh" comes to seek instruction from a "Fenn" relative to Potatoes. Yet so it is, and I beg to inform a correspondent —"Sir Walter Raleigh"—who wants "red varieties and white varieties, both Kidney and Rounds, for exhibition" purposes, that he cannot do better at the present time than to procure the Early American Rose, a flattish obtuse Kidney; and there is a rather early red round, rough-skinned Potato, which I often meet with wrongly shown as the Red Regent; it has various local aliases, but mostly bears the name of the Prince of Wales. If "Sir Walter" can secure it he will gain a fine model for a round red Potato, and well-flavoured, though it is yellow of flesh. The next shapely round, though a later and a larger sort, is Suttons' Red-skin Flourball.

Two models for exhibition, and really first-class second-early white Potatoes, are Thomas Almond's Yorkshire Hero, a flat obtuse Kidney, and Transell's Seedling, Round. I have grown the latter as large as my child's head, but that only happens when two or three tubers are found at one root, which often occurs in a breadth of this variety; and then I know of no other sort that produces such perfect spheres, unless it be the Royal Albert, but that is a smaller, and altogether an inferior kind to Transell's Seedling. It has always been a scarce kind, and should "Sir Walter" find it difficult to procure, there is the King of Potatoes, whose feature is to "run out" in sample, and it would give him both Rounds and Kidneys sufficiently large and shapely to suit. Rintoul's New Early White Don also yields very fine round tubers, and it is withal one of the best modern sorts, a capital market and household Potato.

I recommend the above sorts to be planted on good ground at the following distances apart between the rows:—Early Rose, 2½ feet; Prince of Wales, 3½ feet; Suttons' Red-skin Flourball, 3½ feet; Almond's Yorkshire Hero, 3 feet; Transell's Seedling, 2½ feet; and the New Early White Don, 3½ feet. —Robert Fenn, *Rectory, Woodstock.*

NOTES ON SILPHIUM LACINIATUM, *L.*

THE COMPASS PLANT.

[*Read before the Academy of Natural Sciences of Philadelphia.*]

It is at once the strength and the weakness of science that it takes little on trust. One would suppose that after the positive facts given by President Hill in his paper before the recent meeting of the American Association, there was no room for doubt that the edges of leaves of Silphium laciniatum had an average bearing north. But I find men—excellent acute observers—who doubt the facts. They say, "We took the trouble to examine the plants on the spot, and found not the slightest trace of any such tendency; we want no better evidence than that of our own senses."

As before suggested, it is an excellent habit to verify, for ourselves, the facts reported by others—there is far too little of this habit—but when the observations conflict, it is safer to assume that both are right, and that there is something yet undiscovered which would harmonise the opposition, than that either one is wrong.

In this matter of the Silphium or "Compass Plant," I was able to find this missing link, and to see that both parties were right.

When I first saw the Silphium to any great extent in its native localities, there was not the slightest indications of this northern tendency. It was a great surprise, as a limited knowledge of it before had taught the reverse. I determined to watch a plant carefully on my own ground the next year. The result was just as described by President Hill. There was the unmistakeable northern tendency in the edges of the leaves when they first came up, and until they were large and heavy, when the winds and rains bore them in different directions, and they evidently had not the power of regaining the points lost. This often took place by their own weight alone, especially in luxuriant specimens. Mr. Hill said it was in June when he saw them on the prairies, all bearing north; when I saw them, and not doing so, it was early in September, and then no doubt the mechanical causes I have referred to had been in operation.

The plant I have had in my garden, now for some years, affords much interest in many respects. I learned a useful lesson from it this year in reference to the relative rates of growth in the different parts of the inflorescence. Noticing that there appeared to be no growth in the disk florets in the day, I determined to note accurately, one morning during the last week in August, exactly when growth did commence. The ray flowers close over the disk during night, and at 4 A.M., with day just dawning in the east, I found the ray petals just commencing to open back. In the disk there are about fifteen coils of florets in the spiral. There appeared no motion until 4.40, although no doubt growth commenced at 4, when the ray petals were in motion, but too slow to be perceptible. At 4.40, however, the five outer circles were evidently slightly elevated above the others in the disk. Then follows the following record in my diary:—

4.45, the five divisions of the corolla split open.

4.50, corollas grown three thirty-seconds of an inch.

4.55, divisions of corolla fully expanded.

5, florets two-eighths above the rest of the disk. It might be well to say here, that there was no growth in any this morning but in the five outside rows we are speaking of.

5.5, 5.10, no apparent change except that some which were not so perfectly opened as the others seemed to become so.

5.15, pistil and masses of stamens slightly elevated above the level of the corolla.

5.20, corollas now about five-sixteenths of an inch above the others in disk. Pistils and stamens about two lines above the corollas. Long yellow ray petals half open, with no appearance of pollen on their pistils.

From this time forward there was no further growth of the corolla, so that this portion of the daily labour was accomplished in about three-quarters of an hour.

5.25, pistils and stamens beyond the corolla 1-32 inch.
5.30, " " " 1-16 "
5.35, " " " 1-8 "
5.40, " " " 3-8 "

5.45, 5.50, no change.

5.55, pistils begin to project beyond the stamens. The first insect, a sand wasp appears. He inserts his proboscis down between the clavate pistil and the stamens, carrying away the pollen, which is all over his head.

6, 6.5, pistils one line, stamens no longer lengthen.

6.10, anthers are falling away from the pistils, which are two lines beyond.

6.15, no change.

6.20, the ray petals now fully open, that is horizontal.

No change was noticed after this, except the free visits of the sand wasp, none of these however, carried any pollen to the pistils in the ray florets.

About 9 o'clock (there had not been the slightest indications of any growth since 6.20) heavier insects began to arrive, and then the slightest touch broke off the florets, which fell on the ray pistils which happened to be below them, and in this way they were fertilised. These pistils died very soon after. Those pistils on the upper side (the flower leaning a little) were quite fresh the next morning, awaiting some chance to be fertilised, insects evidently not performing that office.

We here see that there were three phases of growth, with a slight rest between each, the pistil taking the most time, then the stamens, and the corolla the least, but the whole growth of the day included within two hours.

I have used the word pistil for the clavate process which

occupies the place of the true organ in perfect flowers. Of course only the ray florets of Silphium have perfect pistils. This clavate false pistil or ovary has hitherto been supposed to be a necessary production for the fertilisation of the plant. It was supposed to push out the pollen, which was thereby scattered to the ray florets about it. But these observations show that this is probably an error, and that fertilisation is chiefly carried on by the easy falling away of the mass of stamens, as I have shown in a paper on Euphorbia jacquiniæflora in last year's proceedings, is the case with that species.

I am anxious to call particular attention to the different ratios of growth in connection with the appearance of the different floral organs in this plant; because I think I see traces of a general law in plants that there are vibrations or varying intensities during each season's growth, and that the production of the various organs depends on the degrees of these vibrations.—Thomas Meehan.—(*American Gardener's Monthly.*)

GRAPE GROWING IN SCOTLAND.

Scotland has of late years taken a leading position in the production of Grapes. This was first demonstrated at the Great Exhibition of Fruit held in Edinburgh in 1865, where many of the leading Grape-growers of Britain, and even France, put in an appearance, yet first honours were retained in Scotland. Again, in 1869, we had another Grand International Exhibition in Edinburgh, when the triumph of the Scotch growers was as marked as before.

These remarks, however, refer more particularly to Grapes grown in the gardens of the great of the land, and not to such as are grown for commercial purposes. We have, however, to notice a notable step in advance in this latter direction also in Scotland. Some four or five years ago, Mr. Lindsay, of Dryden Bank and Physic Gardens, Edinburgh, who is a most extensive importer of every description of green fruit, built at his country residence two splendid vineries, each 160 feet long and about 18 feet wide. These are built on what may be called the lean-to principle. Their construction and heating are of the most substantial character. Their borders were formed after the most approved method, and the results have been highly satisfactory—the crops of Grapes having given ample evidence that the foundation was well laid, and the after-management all that could be desired. We believe Mr. Thomson, of Dalkeith Park, was the architect of Mr. Lindsay's vineries, and we are going to refer to what he is now doing in the same direction for himself in Selkirkshire, where he has feued land near the Clovenfords Station of the railway leading from Galashiels to Peebles, about three miles from Galashiels and one mile from the classic grounds of Ashiestiel, where Scott wrote the greater portion of "Marmion," and from which he dates many of the introductions to his cantos. We believe Mr. Thomson selected this spot because of the excellence of the soil for Grape-growing, the supply of water, and the facility with which the fruit can be sent on to London by express trains from Galashiels. He has named his establishment The Tweed Vineyard, but Grapes are not the only fruit he means to produce; he has made arrangements for fruiting about a thousand Pines annually, besides Melons, Cucumbers, and other fruits. It is but a year since he got possession of the ground, and those who have seen the place recently can only marvel at what has been done in so short a space of time. Hothouses have been erected requiring thirty tons of glass to glaze them, and three miles of hot-water pipes to heat them.

The great central blocks of glass for the production of Grapes consist of three span-roofed houses, each 200 feet long, 24 feet wide, and 17 feet high. These are placed 24 feet apart, and parallel to each other, terminating at one end in a house running along their ends and forming a corridor for them; this corridor is of the same height, 135 feet long, and 25 feet wide, and in it are placed all the appliances by means of which the ventilation of the whole block of glass is effected; it is interesting to observe that this is done in as little time and with as great ease as an ordinary three-light frame, such is the perfection of the gear employed. Two of the long houses have eight rows of pipes in each, one has twelve rows, and the corridor has ten rows. This, with some connecting pipes, gives 7000 feet of 4-inch pipe, which is all heated by one boiler, of an entirely new construction, which Mr. Thomson has had constructed of boiler plates. It might be called the telescope boiler, for it is some 20 feet long. The Vines are all of the most approved sorts.

In addition to this grand block there is a pinery 120 feet long and 13 feet wide against the boundary wall; another 145 feet long and 13 feet wide; a third 200 feet long and 5 feet wide along the front of a Cucumber house of the same length and 13 feet wide. In addition to these there is a Pine pit in course of construction 200 feet long, and a plant house 100 feet long. The Cucumber house, it is calculated, will produce in four months three hundred dozen fruit—more, probably, than is consumed in Scotland in a whole year.

The Vines with which the vineries have been planted were all struck from eyes and grown on the spot, and they have made such progress that about 3000 lbs. of Grapes may be expected from them next summer by cropping a set of Vines called supernumeraries, which will be removed when the permanent ones completely occupy the houses. Such extensive preparations for supplying the market with Grapes, when taken in connection with many similar establishments that exist, especially in England, must of necessity diminish the cost price of hothouse Grapes, and bring them within the reach of a class of the community from whom their cost hitherto has excluded them; and in this we rejoice, especially when we consider what a boon they must be to invalids and all who are of delicate constitutions, proving to them both food and drink when they often loathe everything else.

We learn that Mr. Thomson has resigned the situation he has held for so many years as gardener to his Grace the Duke of Buccleuch at Dalkeith, and in May will take the personal superintendence of The Tweed Vineyard. Mr. Thomson is well known to be the highest authority on Grape cultivation in this country, and in the foremost rank as a practical cultivator. The important enterprise now undertaken on the banks of the Tweed could not have been inaugurated under more auspicious circumstances.—(*Daily Mail*)

SLOW COMBUSTION—ECONOMY OF FUEL.

For "A. Y.'s" information (see page 8) I may state that the valve is fixed on the ashpit, and not on the furnace door, and that both doors fit quite closely. Although the valve answers admirably, yet I quite agree with Mr. Fish that a single hole with a screw valve would be preferable to my sliding valve, as I think it could be more accurately regulated. I had an opportunity only last week of observing the working of one in a close stove in a large warehouse, and saw at a glance that it was preferable to my sliding valve. Nevertheless, I have no fault to find with my present plan. It has been fairly tested during the present severe frost, and it has proved to be all I could desire in its results.

It was only the other day that the builder (a nurseryman) who constructed my house called, when I asked him to look at the furnace. Upon seeing the fire he immediately remarked, "That's capital; it is perfect; you cannot want anything to work better." It was then half-past 9 A.M., and the fire had been made up at half-past 8 the previous night, and had consequently been burning for thirteen hours, and still was a good fire. The thermometer showed at the time 16° of frost in the external atmosphere. The glass inside the house stood at 40°.

The fire was made up last night at a quarter-past 9; at half-past 9 this morning there was still a good fire. The thermometer inside the house marked 45°. The frost during the night had not exceeded 4°. I mention these particulars to show how the plan has worked during this severe weather.

In stating the quantity of fuel used to burn the length of time I have mentioned, I will give my experience as correctly as may be. I cannot give the quantity of coal, but "A. Y." will probably be able to form a tolerably accurate estimate. He must bear in mind that I use a tubular boiler of the smallest size, and that I burn anthracite coal only. The boiler is fixed about 6 or 7 inches above the firebars, and the diameter of the furnace below the boiler is about 21 inches.

When I make up the fire for the night I fill up to about 4 inches above the bottom of the tubes in the inner circle of the boiler. The fire in the space between the outside of the tubes and the brickwork is below the boiler; the fuel, in fact, forms a flat-topped cone-shaped mass. Were I to fill up higher than I have stated, the heat would be too great. My consumption of coal is as nearly as possible half a ton per month. I may add that since I have used anthracite coal I have never been troubled with clinkers; the firebars are always clear.

I should, perhaps, mention that the inside course of brickwork in the furnace is made of firebricks.

I hope this information may be of use to "A. Y." He must

remember that I only give the result of my experience with one kind of boiler and one description of fuel. I do not pretend to state that similar results would follow with different materials to work with. I merely give my experience, and how obtained.

From observation I am disposed to think that if I had to construct another furnace I should make the space greater between the boiler and the firebars; instead of 7 I would make it 12 or 14 inches, contracting the sides towards the bottom. By this plan, as the fire burnt out, it would drop closer together, and keep burning, instead of going out, as it does in broad-bottomed furnaces. The quantity of fuel consumed would not be greater than, probably not so much as in the ordinary way of setting furnaces.

I remember the old-fashioned circular-bottomed stoves used in bedrooms. As the fuel burnt the fire dropped down closer, and kept bright for a long time; whereas, with the modern broad flat-bottomed stoves, the fuel is soon burnt right out. If something like the principle of these old-fashioned grates were applied to greenhouse furnaces, making them for slow combustion, as great or greater results would be obtained with less trouble and a smaller consumption of fuel.

Does Mr. Fish think a screw-valve in the fireplace would be an improvement?—R. S.

GROUND LEVELLING AND PRACTICAL GARDEN PLOTTING.—No. 11.

DRAWING PLANS.

To draw and transfer *fig.* 34 to the ground, form the rectangle A B C D; draw the diameter lines E F and G H, also the diagonal lines A C and B D; draw the other lines 1 2, 3 4, &c. (being parallel to either diameter or diagonal lines); draw the circle from centre O, also the arcs as shown in *c* and *d*.

To transfer the figure to the ground, lay a line from A to B, the distance being 41 feet 6 inches, also from B to C, being 62 feet; lay the line from C to D, which is equal to line A B, lay the line from D to A, which is equal to line B C; insert a stake at each point. Lay the diameter lines E F and G H, insert a stake at each point; also lay the diagonal lines A C and B D. From the stake at point A measure 2 feet on line A B, insert a peg as at point 1; also from stake A measure 2 feet on line A D, and insert a peg as at point 23. From stake B measure 2 feet on line B A, and insert a peg as at point 11; also from stake B measure 2 feet on line B C, and insert peg as at point 24. From stake C measure 2 feet on line C B, and insert peg as at point 14; also from stake C measure 2 feet on line C D, and insert peg as at point 12. From stake D measure 2 feet on line D C, and insert peg as at point 2; from stake D measure 2 feet on line D A, and insert peg as at point 13. Lay lines connecting peg 1 2, 11 12, 13 14, and 23 24. On each side of the diameter line E F measure 18 inches, and insert pegs as at points 17 18, 19 20. From the stakes at points E F on each side measure 3 feet 6 inches, and insert pegs as at points 15 16, 21 22. Lay lines connecting pegs 15 16, 17 18, 19 20, and 21 22. On each side of diameter line G H measure 18 inches, and insert pegs as at points 5 6, 7 8. From the stakes in points G H measure 3 feet 6 inches, insert pegs as at points 3 4, 9 10. Lay lines connecting pegs 3 4, 5 6, 7 8, 9 10. On each side of the diagonal lines A C and B D measure 2 feet, as shown in points C and D; extend line B A to *b*, which is 2 feet, insert a peg as at point *b*; extend line D C to *a*, and insert a peg as at point *a*; lay a line from peg *b* to the peg at point 12, and from the peg at point 1 to the peg at point *a*. From stakes B and D find corresponding points to *b* 12 and 1 *a*; lay the corresponding lines. Extend the line A B to *u*, which is 4 feet 3 inches, and insert a peg as at point *u*. From the stake at point B measure 4 feet 3 inches on line B A, and insert a peg as at point *r*. Extend line C D to *s*, which is 4 feet 3 inches, and insert a peg as at point *s*. From stake D measure 4 feet 3 inches on line D C, and insert peg as at point *t*. Then lay a line from peg *r* to peg *s*, and from peg *t* to peg *u*. From the stakes at points A C find the corresponding points to *r s* and *t u*, and lay the corresponding lines. From the centre, with a string 9 feet 6 inches long trace arcs c, c, c, c; reduce the string 2 feet, and trace arcs *d*, *d*, *d*, *d*, *d*, *d*, *d*, *d*; reduce the string 3 feet, and trace the circle 9 feet in diameter. Lay lines to the arcs (with pegs as before described), also to the circle, which com-

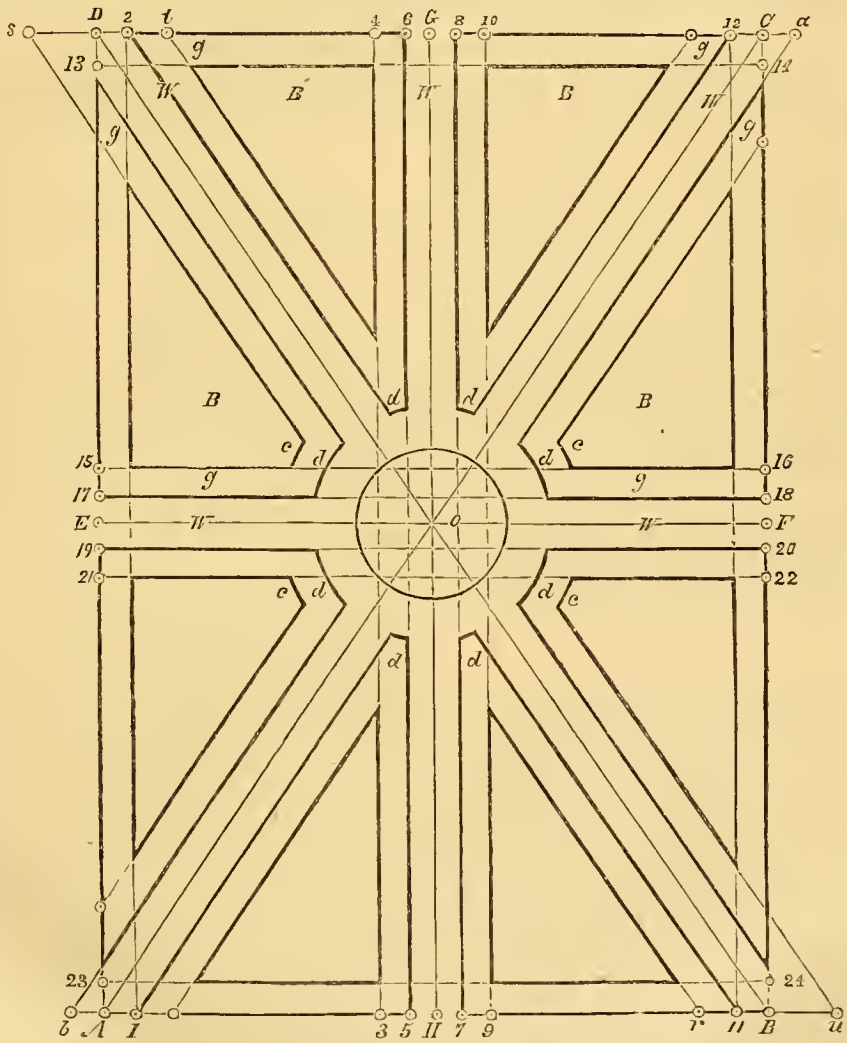

Fig. 34. Scale 12 feet to the inch.

plete the figure. The points where the lines cross each other are the angles of the beds and grass verges. B, beds; *g*, grass; W, walks.—M. O'Donnell, *Gardener to E. Leeming, Esq., Spring Grove, Richmond.*

ORNAMENTAL VARIETIES OF OUR NATIVE PLANTS.

I have been looking out amongst our British plants for ornamental and variegated forms, or any departure from the normal condition, with a view to selecting such as may be thought worthy of a place in our gardens. I have been rewarded with many interesting varieties of Grasses, Veronicas, Lamiums, Glechomas, &c. The variety of Malva sylvestris called crispa must become a favourite winter-garnishing plant, as I see the French Mallow is cut-up with the frost, and my Mallow will stand any amount of cold without injury. The Grass, which I think is Poa annua, is considerably shorter in its growth and flower stems than Poa trivialis argentea. I have also a new Dactylis glomerata, the whole foliage assuming a creamy-white tint in the spring, but not so good in the summer, and a Phleum pratense aureo-variegatum, which is very ornamental during the summer. I was the raiser of Bull's Holcus lanatus variegatus, Alopecurus pratensis variegatus, and Phleum pratense albo-marginatum; also Henderson's Lamium aureum, and Thymus citriodorus aurens, and a new variety of Sedum acre, and of Helianthemum vulgare, to be sent out by a London firm as soon as sufficient stock shall have been raised.

My stock of new British plants comprises some one hundred sorts of greater or less merit, and I can assure you that my wanderings in search of novelties have been a labour of love. Some of these plants have been propagated from the most trifling beginnings. The Mallow, for instance, I discovered on the wayside at Old Charlton, Kent, with only one curly leaf upon the plant. I dug it up, potted it, and it produced another curly leaf or two, all the rest of the foliage being perfectly plain. I gathered the seeds from the side of the shoot with the curly leaves, and they produced a progeny with some plants all curly, some all plain, and some partly curled; but the parts of partially-curled plants that were curled were as well curled as the plants that were all curled, and I find that the all-curled plants come perfectly true from seeds. Being very prolific it will make a cut-and-come-again garnishing plant from the autumn till late in the spring, when it loses all its crispness and cannot be distinguished from the normal state till the autumn again comes round.

I have also a new gold-striped Lily of the Valley, and several beautiful forms of Arum maculatum—viz., aureo-marginatum, and albo-marginatum.

My plants are all original and collected by myself, and although there have been varieties of variegated plants, such as Glechoma and Veronica, found before, there are in every fresh one differences which are very interesting.—Wm. Elliott.

[We hope to hear often from Mr. Elliott on this subject.—Eds.]

THE METROPOLITAN FLORAL SOCIETY.

It will, I am sure, interest some of your readers to know what progress we are making in our attempt to bring more prominently into notice those favourites, yclept florists' flowers, which we believe have been too much shoved out of the way by things more easily managed, but, we think, not half so beautiful.

I need not say that there was an immense difficulty in organising a new Society; for many would be ready to imagine that it was the result of spleen, and, as I had had a pretty continuous fight with the existing Societies (especially with the Royal Horticultural Society, on what I honestly believed to be blunders and mismanagement), that in a spirit of opposition I had originated this movement. As I felt perfectly at ease on this score I did not much care what some might think, so long as the point we had in view was gained. The liberality with which our advances were met by the Crystal Palace Company, and the kind thoughtful manner in which the arrangements were carried out by Mr. Wilkinson, tended to make our first show the most successful autumn exhibition ever held in the metropolis. Thus encouraged we have made another move. We felt that it would never do to originate separate exhibitions—that would have had the appearance of opposition; moreover, we could not have made them sufficiently attractive, and we could not run the risk of failure. We therefore felt that it would be better to connect our prizes with some existing machinery. The months in which we proposed to offer prizes were April for Auriculas, May for Tulips and Pansies, June for Ranunculuses and Pinks, and July for Carnations and Picotees. In the first and last of these months it was decided that it would be desirable to connect our exhibitions with the Royal Horticultural Society, and in May and June we felt that there was no choice left, as the Crystal Palace Company had offered to help us materially in our prize list. Communications were opened with the Council of the Royal Horticultural Society, and arrangements were made advantageous to both. The Royal Horticultural Society will gain the advantage of having, we hope, an attractive addition made to two of their minor shows, while we shall gain a place to exhibit our flowers where they will be seen by many lovers of flowers.

These preliminaries having been arranged, a meeting of the Committee was held at St. James's Hall on Tuesday the 3rd inst. to determine what was to be done. The Committee felt that it would be very unwise to venture too much. Societies are often vigorously taken up at first, and then people cool on them; and if plans are arranged on the larger scale, then there comes the necessity of clubbing together to pay debts—a most unprofitable proceeding. Hence if the schedule of prizes agreed upon may seem to be small after so much talking about them, let it be remembered that our motto is "*festina lente*," freely translated, "Slow and sure goes far in a day."

I should add that the Royal Horticultural Society have consented to the Society having their own judges. We propose, therefore, to offer the following prizes to be competed for by members of the Metropolitan Floral Society alone:—

In April—6 Auriculas (amateurs)	£2,	£1,	10*s.*
1 do. Green edge (open)	7*s.* 6*d.*,	5*s.*,	2*s.* 6*d.*
1 do. Grey edge (open)	7*s.* 6*d.*,	5*s.*,	2*s.* 6*d.*
1 do. White edge (open)	7*s.* 6*d.*,	5*s.*,	2*s.* 6*d.*
1 do. Self (open)	7*s.* 6*d.*,	5*s.*,	2*s.* 6*d.*
In May—36 Pansies (open)	£2	£1 10*s.*	£1
24 do. (amateurs)	£2	£1 10*s.*	£1
12 Fancy Pansies	£1	15*s.*	10*s.*
36 Tulips (open)	£2	£1 10*s.*	£1
12 do. (amateurs)	£2	£1 10*s.*	£1
In June—24 Pinks (open)	£2	£1 10*s.*	£1
12 do. (amateurs)	£2	£1 10*s.*	£1
24 Ranunculus (open)	£2	£1 10*s.*	£1
12 do. (amateurs)	£1 10*s.*	£1	10*s.*
In July—12 Carnations (amateurs)	£1 10*s.*	£1	10*s.*
12 Picotees (amateurs)	£1 10*s.*	£1	10*s.*

The prizes offered at the autumn show will be on the same liberal scale as last year. Having thus explained our present position, I hope that we shall receive such additional encouragement as will enable us another season to place a more liberal scale of prizes for the florists to compete for. Our object is not only to encourage those who already cultivate florists' flowers, but also to induce others to attempt or recommence their culture.—D., *Deal.*

A MAMMOTH BLACKBERRY ORCHARD.

One of the most interesting calls we have made this year was to the great Blackberry patch of John S. Collins. The following, from the *Practical Farmer*, gives an excellent idea of things as we saw them.

We visited about the middle of the past month, approaching but not quite at the height of the picking, the large Blackberry patch of our friend, John S. Collins, near Merchantville, New Jersey, about four miles from Camden. It comprises seventy-five acres, all planted in Blackberries, and now bearing profusely, but far yet from being up to its maximum production. They were planted mostly three and four years ago.

The day of our visit, 7000 quarts had been picked; 14,000 quarts were fully expected the day following, which would be a full day's work for the hands employed, who, when we saw them, were quietly resting or lounging about under the shade of trees, and recruiting for the morrow—7000 quarts being about half a day's work. A visitor to this patch would at once be satisfied that there is many a homely adage less truthful than the very trite one, "as plenty as Blackberries." Here were seventy-five acres occupied with nothing else than Blackberry plants—thousands of the bushes bending nearly to the ground under their weight of fruit. The rows were 8½ feet apart, and the plants 4 feet to 4½ in the rows. The tillage had been excellent, no weeds at all to be seen, for the simple reason, we presumed, without asking the question, that the berries brought a better price in the market than weeds, and the proprietor, being essentially a practical man, had given the strength of the soil and the labour of cultivation to the crop which brought in the most

money. People's mental organisations differ widely, as also their reasoning processes and conclusions. This was indicated by a field adjoining the Blackberries, where the owner had evidently concluded that the crop for him to raise was "mullens." We have seen no "mullen" crop equal to them this season, and think we never saw a better one anywhere. They have grown 6 feet high, without any expense of cultivation. The inference we drew was, that a "mullen" soil was also favourable for Blackberries.

By far the largest portion of the Blackberries were the variety known as Wilson's Early. This seedling, of a few years since, ranks in importance with the Philadelphia Raspberry. It is the best Blackberry out, has been tested thoroughly, differs from the Lawton in being ripe when black, is of good size, melting, and juicy, which, with its earliness, being the first in the market and treading closely on the heels of the Raspberry crop, always secures the best price.

J. S. Collins was receiving 20 cents per quart, wholesale price, at the time of our visit, which, with 14,000 quarts, make the round little sum of 2800 dols. for one day's picking. Can the "mullen" grower show as large a record?

One of the most interesting features of the business, to us, was the quiet, thorough, and systematic manner in which everything was done. Each row had a marked stake at the end. Hand A undertakes to pick rows 55 and 56—was so marked by the clerk in his book, and they were required to pick them clean, and to go back if they were not so. The price paid for picking was 1½ cent per quart, and a constant supervision being exercised over the work, the hands soon discovered it was easier to pick a row thoroughly than to have to go back. Very few cases occur where they are so continually careless as to require to be discharged. The average is 100 to 150 quarts per day to each hand, but they sometimes run up to 200 quarts per day.

While a harvest was being evidently reached by the intelligent and far-seeing projector of this Blackberry patch, it was also no less a Blackberry festival for the hands employed. On inquiry where they were from, we were surprised to find them to have come mostly from that aristocratic (?) portion of Philadelphia, Bedford Street. Is it possible, thought we, thus to utilise Bedford Street? Here were one to two hundred hands employed, of what is known as the very scum of creation, men with their wives and children, gathered about in clumps; and in passing among them, we did not hear a profane or improper word, all quiet and orderly. The change from damp and crowded cellars and filthy dens and alleys, to the green grass and pure air and beautiful trees of the country, where all Nature was pleasant, and the birds sang merrily, most evidently impressed and reached the latent spark of these depraved specimens of humanity. As they stay over the Sabbath, what a place and an opportunity for those rightly qualified to give religious labour for operating on such a class.

As the filled boxes are brought up to the clerk, 3-ct. or a larger denomination of tickets are given out, which are always good for the money whenever asked for. The ticket system undoubtedly induces them to save till toward the end of the season.

A large open shed is erected, with rough tables and benches, which may be called the restaurant, where plain meals are cooked, and provisions sold, of course with the entire absence of intoxicating liquors. The barn as well as shanties erected about, are used to lodge in; and there can be no doubt the hands return, when the season is over, improved in mind, body, and estate.—(*American Gardener's Monthly.*)

THE CANDELABRA-FLOWERED LARKSPUR.

I DO not very much affect annuals, although some of them are remarkably handsome, but one was sent to me last year by Messrs. Dick Radclyffe & Co. under a name quite sufficient to deter anyone from growing it—Delphinium Consolidum candelabrum flore-pleno. However, I tried it, and can conscientiously recommend it as one of the prettiest things I know in its way. It is dwarf, and the arrangement of the branchlets is exactly like that of a candelabrum. They go out horizontally from the stem, and then the flower stands up in a perpendicular position. It is of various shades of colour, and altogether it is a very great addition to our pretty annuals.—D., *Deal.*

FROST AND SNOW IN NORFOLK.—Snow 1 foot deep. The thermometer (Negretti's) registered on December 24th, zero; on December 25th, 4° below zero. The thickness of the ice on the lake on December 26th was 5 inches. This is the coldest weather we have experienced here since December 25th, 1860.—WM. SMYTHE, *The Gardens, Elmham.*

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

ONCIDIUM TIGRINUM *var.* SPLENDIDUM (Splendid Tiger-marked Oncid). *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—Native of the Irapæan Mountains, Mexico. Flowers pale yellow striped with brown.—(*Bot. Mag.*, *t.* 5878.)

PAULLINIA THALICTRIFOLIA (Thalictrum-leaved Paullinia). *Nat. ord.*, Sapindaceæ. *Linn.*, Octandria Trigynia.—A stove climber with graceful Davallia-like leaves. Native of Rio de Janeiro, Brazil.—(*Ibid.*, *t.* 5879.)

ARISTOLOCHIA DUCHARTREI (Duchartre's Birthwort). *Nat. ord.*, Aristolochiaceæ. *Linn.*, Gynandria Hexandria.—Native of the Upper Amazons. Flowers cream-coloured, thickly blotched with reddish brown.—(*Ibid.*, *t.* 5880.)

HÆMANTHUS TENUIFLORUS *var.* COCCINEUS (Crimson Slender-flowered Hæmanthus). *Nat. ord.*, Amaryllidaceæ. *Linn.*, Hexandria Monogynia.—Native of Abyssinia. Flowers crimson.—(*Ibid.*, *t.* 5881.)

ASYSTASIA VIOLACEA (Violet-coloured Asystasia). *Nat. ord.*, Acanthaceæ. *Linn.*, Didynamia Angiospermia.—Native of Concan, western Peninsular India. Flowers pale purple with white border.—(*Ibid.*, *t.* 5882.)

PEAR—*Brockworth Park.*—"Messrs. J. C. Wheeler & Son, of Gloucester, have acquired the stock, and it was obtained by them from Mr. Lawrence, of Brockworth Park. It is, as we understand, a seedling raised at that place, one of its parents being the well-known and highly-esteemed Louise Bonne of Jersey.

"The Brockworth Park Pear is a fruit of large size, the specimens figured measuring 6½ inches in length and 9½ inches in circumference. Its form is oblong-pyriform, blunt and rather unequal at the base, with a stout obliquely inserted stalk about an inch long, set in a shallow basin, and having a small closed eye, with prominent pointed calyx segments. The skin is smooth, pale greenish yellow, slightly dotted, and with a delicate irregular tinting of red on the exposed parts. The flesh is very tender, fine-grained, and melting, with abundant rich vinous juice, the flavour very much resembling that of its parent, the Jersey Louise Bonne; but the fruit is much larger and handsomer than in that variety. It comes into use about the middle or end of September.

"The tree is described as being hardy, of ornamental growth, and a very free bearer, young pyramids each producing as many as twenty fine Pears. When grown against a wall the fruits are said to average 12 ozs. in weight. Altogether we have here, in the words of one of our leading pomologists, 'a new Pear of the highest merit, taking rank with the finest of our old-established varieties, and one which, extensive as our list of good Pears already is, must yet be added to our collections.'"—(*Florist and Pomologist*, 3 s., iv. 1.)

NOTABLE PEARS.

AUTUMN JOSÉPHINE.—A seedling from Joséphine de Malines. This fine Pear rivals its parent in all its excellencies, and differs only in the season at which it ripens.

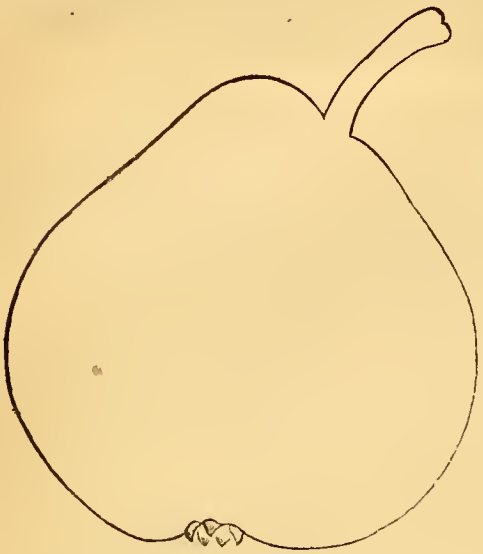
The fruit is even and regular in its outline, turbinate, and somewhat flattened at the crown. The skin is greenish yellow when quite ripe, and strewn with patches of thin pale brown russet, and with a russet patch round the stalk. Eye open, with short erect segments, and set in a shallow depression. Stalk three-quarters of an inch long, woody, and inserted without depression. Flesh yellowish, with a pale salmon tinge, like that of Joséphine de Malines, tender, fine-grained, and very juicy. Juice rich, sugary, and with a fine aromatic flavour.

A fine Pear, ripe in the middle of October, and lasting about a fortnight.

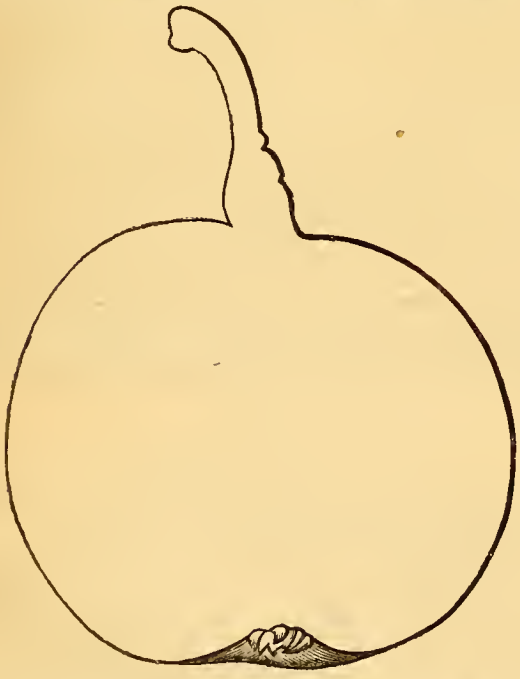
This valuable native acquisition was obtained from seed by W. E. Essington, Esq., of Ribbesford House, Bewdley. The seed, which was obtained from Joséphine de Malines, was sown in the year 1856, and scions from the seedling were grafted on the stock of a worthless Pear tree, which had been cut down in 1861. The tree is an excellent grower, and has formed a large head, bearing two bushels of fruits, and it first produced fruit in 1869

Cassante du Comice.—Fruit roundish, or Bergamot-shaped, a little uneven on its surface. Skin of a dull yellow ground colour, considerably covered with rough brown russet, which leaves large patches of the ground colour visible. Eye partially closed, with incurved segments, and set in a considerable depression. Stalk 1¼ inch long, curved, and with a large swollen fleshy base, the upper part woody. Flesh yellowish, coarse-grained, crisp, and very juicy, with a rich, sweet, sugary juice.

A first-rate dessert Pear, ripe in the last week of September.



Autumn Joséphine.

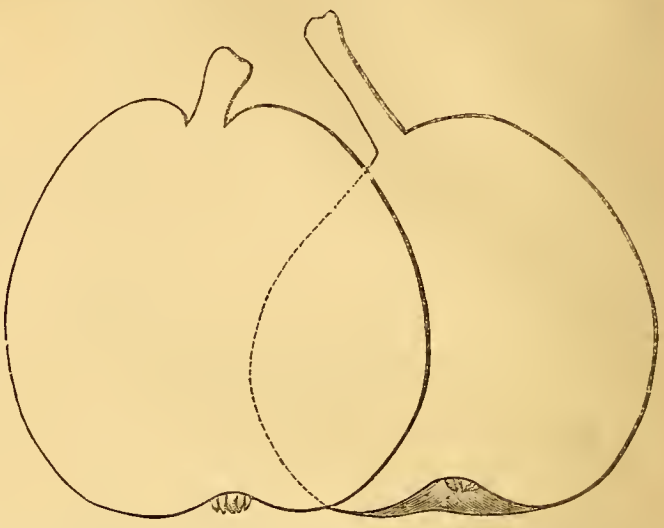


Cassante du Comice.

This was raised by the Horticultural Society of Angers, and I received it from M. André Leroy of that city.

Gansel's Seckle.—Though one of the very best of our native Pears, this is one which is little known and very seldom met with. It is one of the seedlings of the late Mr. Williams, of Pitmaston, to whom we are indebted for so many excellent new fruits. It was obtained by crossing the Seckle with Gansel's Bergamot, and hence its name.

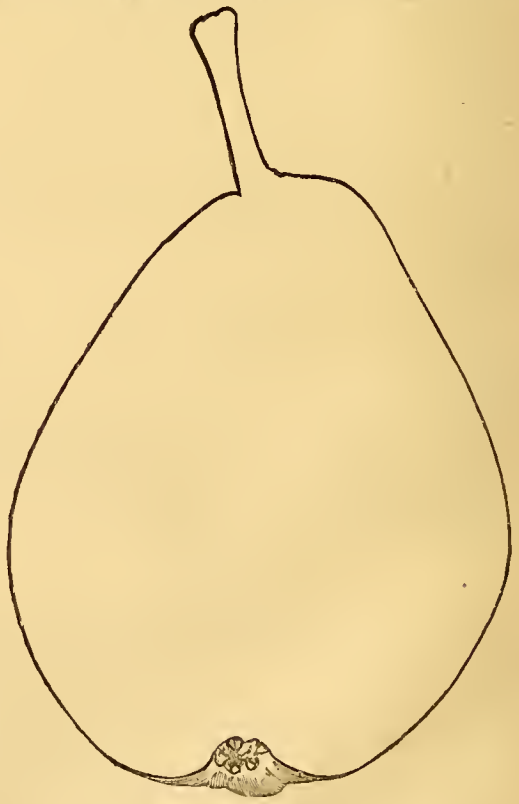
Fruit not unlike the Seckle in shape, and also with much of the character of Gansel's Bergamot on a small scale. The skin has a solid bright crimson cheek next the sun, which shades off to yellow on the opposite side; the shaded side is covered with a thin smooth crust of cinnamon-coloured russet, and the crimson cheek is strewed with distinct dots of grey russet. Eye small and closed, with erect acute segments, set in a narrow and considerable basin. Stalk generally short and stout, but sometimes three-quarters of an inch long, inserted in a narrow and rather deep cavity. Flesh yellowish, rather coarse-grained and gritty, with a sweet, abundant, and very richly-sugared juice, and a high perfume, but not so much so as in Seckle.



Gansel's Seckle.

A first-rate Pear, ripe in the beginning of November.

Maud Hogg.—The fortunate raiser of that excellent Apple Mannington's Pearmain has been equally successful in raising a number of seedling Pears, some of which will, we have no doubt, become established varieties in British gardens. A native of the Weald of Sussex, where no more uncongenial soil and climate for delicate varieties of fruits could be found, this new



Maud Hogg.

gain of Mr. Manningtou's, which we now describe, has proved itself to be an autumn Pear of great excellence.

The fruit is above the medium size and oblong-obovate. The skin is entirely covered with a crust of warm brown russet like that of the Brown Beurré, and has a slight orange glow on the side exposed to the sun very much like the Chaumontel; there is no yellow or ground colour visible. Eye open, with very short segments, and set in an irregular ribbed depression. Stalk an inch long and rather slender, inserted without depression. Flesh yellowish white, tender and buttery, very juicy, sweet, and richly flavoured.

A dessert Pear of the first quality. In use from the end of October and beginning of November till December.

The seed was sown about sixteen years ago, and the tree has borne fruit this year for the first time.—(*Gardeners' Year Book*, 1871.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

Where there is a family of taste to be supplied, perhaps no department requires more energy and forethought than this, because the demand is constant throughout the year. We have not only to look at present wants, but must have regard to the future. Now is the time to do so. Manuring and trenching as fast as the crops are cleared off will still be the principal work here; turn over compost heaps during the frost, and procure a fresh supply if needful. Draining—an important matter in flat damp situations—should be done when opportunity offers. A well-drained garden is generally a productive one. If Box edgings are used, repair them if necessary in open weather. If they have grown large and unsightly, reduce them by relaying. This is done by clearing away the gravel, &c., digging the ground, picking out any stones or roots of the old Box, then treading the soil firm, levelling with the spade, cutting out a neat line, and placing the Box (after reducing it to small plants), in the opening, leaving an inch or two above ground. Make the soil level over the roots, and level the gravel to it, keeping the rough part downwards, and making smooth and firm on the surface. Large edgings are unsightly and shelter snails, &c. Every vacant space should be turned up to expose the soil to the action of the weather, either by trenching and laying it up in ridges, or by deeply digging and laying it up in the same way. If manure cannot be dug into the ground, rather than have it wasted by exposure, throw a covering of earth over the surface to prevent evaporation till it can be used. If snow should be on the ground, it should not be dug in, as it would keep the soil cold and wet for a long time. See that previous directions are carried out; if not, embrace the first opportunity when the state of the soil will admit. It is bad policy to tread upon trenched ground when saturated with wet, and the delay of a day or two will often be found a gain. To guard against possibilities, sow in pots or boxes, or on strips of turf, a moderate quantity of early *Peas* and Long-pod *Beans* for transplanting. Place them in a vinery at work, or a house where there is a gentle heat, and when about an inch high remove them to a cold frame secure from frost to be hardened off. Sow *Onions* in a warm corner for early spring use, and plant out small ones of last year's growth for the same purpose, and to bulb for kitchen use. Plant out *Shallots* and *Garlic* in light rich soil. Draw a small drill and fill it with charcoal dust or charred refuse, and lay the bulbs on it, but do not cover them; they will by-and-by require a slight pressing down. See that the fermenting material round *Sea-kale* does not become too hot; begin in time, and give it a slow gentle heat or you will have it as weak as straws. Cover up a succession, taking care to place pots or a substitute over the crowns to keep it apart from the fermenting matter, for notwithstanding covering with leaves and ashes without pots, nothing seems to entirely do away with the earthy flavour which it thus acquires. *Spinach* appears to have suffered much from the frost; let all decayed leaves be carefully removed, and the ground stirred the first opportunity. Keep a succession of *Small Salading* sown in pots or boxes, and attend to the protection of *Lettuces*, *Endive*, *Radishes*, and *Cauliflowers* in severe weather.

FRUIT GARDEN.

If not done in the autumn prepare and wheel in soil for fruit trees which are to be removed, or which are intended for filling-up vacancies on the walls. This, however, is far better done at the fall of the leaf. See that the drainage of the border is perfect. Continue pruning and nailing in favourable weather, and as fast as the trees on the wall are completed manure the border and turn it up. The quantity and quality of the manure must depend upon the crops taken from the borders; it is never advisable to plant any very exhausting crops on them, but I am aware that in many gardens doing so can hardly be avoided, and where this is the case, fresh soil and manure must be added. A great objection to digging-in manure on fruit borders where the roots can take hold of it is, that it causes unfruitful luxuriance, but unless cropping the borders can be altogether dispensed with, it can hardly be avoided.

FLOWER GARDEN.

As soon as the frost ceases, any ornamental planting necessary should be proceeded with. Clean, dress, and dig borders, and renew soil where necessary, for the reception of gay flowers. Stations on the lawn may also be prepared for tree Roses or ornamental shrubs, remembering not to carry the dotting system so far as to destroy what the painter calls breadth.

GREENHOUSE AND CONSERVATORY.

A day temperature of 55° will be quite sufficient here at present; if this cannot be maintained without strong fires, be content with 45° and moderate fires, remembering that with this low temperature a very small circulation or motion in the air will suffice. A higher degree of heat would hurry the beautiful Camellias and other choice flowers past their blooming period, and create a necessity for the application of more atmospheric moisture, which, unless a warm roof is secured by covering, must end in drip, to the great prejudice of the delicate blossoms. Those who possess only one small greenhouse, and are desirous of a variety of early flowers, may now introduce from the cold frame or pit a few of the early Dutch bulbs, provided the pots are full of roots, without which the application of heat is vain. They should be kept in the darkest part of the house, or what will be more congenial to their habits, covered overhead with a mound of soil. The two points are easily accomplished by first piling a mound (moss would do), and then inverting a pot over the whole. The Wind or Poppy Anemone, established in pots, makes a pleasing variety; also the dark Wallflowers, as well as the French Yellow. Let all plants of a hardy nature have a place close to the front glass, with air at every opportunity. Some of the plants named in the directions for the forcing pit may also be introduced here if there be room, provided such are well-established in their pots.

STOVE.

Little advance in temperature may be permitted here at present; wait for an increase of light, without which the application of heat and moisture will be vain. Let 60° without sun be the maximum, sinking 4° or 5° in the night. Some of the Lælias and Cattleyas will commence rooting; let them have attention and encouragement. Cymbidium sinense is a most useful plant for the drawing-room; the scent is most delicious. A thorough baiting for snails and vermin should take place previous to potting.

FORCING PIT.

In the tank forcing pit the following plants may be now introduced with every prospect of success, if they are in good order:—Franciscæas, Gardenias, Hedychiums, Gesneras, Phajus, Daphnes, Chorozemas, Clerodendrons, Pultenæas, Correas, Cytisus, Eranthemums, Honeysuckles, Sweet Briar, Roses, Lilacs, Azaleas, Dutch bulbs, Acacias, Pinks, especially Anne Boleyn, Aloysia citriodora, Hydrangeas, and Heliotropes. It is not meant that these are all equally eligible for forcing, but that any or all of them may be attempted if well prepared for the purpose in the previous summer by early growth, early rest, and making a potful of healthy roots. With such a miscellaneous mixture it is evident that no extreme of atmospheric management should be pursued. The amount of moisture which the Gardenias, for instance, would revel in would prove prejudicial to such plants as the Heliotrope. A day heat of 60° or 65° will suffice at present, sinking the temperature at night to 50° or 55°.—W. Keane.

DOINGS OF THE LAST WEEK.

After a severe frost on the night of the 5th the thaw commenced very suddenly during the day of the 6th, and on the morning of the 7th hardly a patch of snow was to be seen, but, instead, many lakelets were visible, as the ground beneath was so hard that the melted snow could not at once sink in. The sudden melting of the snow will help to fill many a pond, which will be useful in this district, where in summer there is a

general scarcity of water. As the sun shone brightly for a time on the 6th, we were glad to give a peep of light to Violets, Calceolaria cuttings, and Radishes in cold pits that had had scarcely a peep of light for a fortnight. Some things rather tender, or where there were the least signs of the frost, were left with a slight covering all day, so as to become gradually inured to the full light, as alluded to last week. Thanks to a little litter which we saved from stable dung in summer, the frost has done us but little injury as yet, for the most forward Cabbages, &c., were protected by snow.

KITCHEN GARDEN.

Here work was reduced to a minimum, as beyond wheeling nothing could be done. A little litter was shaken over Broccoli as the snow began to move off, to keep the heads from the sun until they were thoroughly thawed. Young Cauliflowers were not uncovered until Saturday. Forward Lettuces a little frosted will have comparative darkness until the beginning of the week. The excessive frost taught us also the importance of looking before us. We should have liked to have taken up for the Mushroom house more Sea-kale, Rhubarb, Asparagus, &c., but the ground was too hard to permit of this being done with anything like justice to the roots. We generally keep some taken up well covered in a cool place, to be taken for use as needed; but the winters on the whole have lately been so mild that we neglected to have much in reserve, and we should have felt it if the weather had continued a fortnight or three weeks longer, which would have been nothing strange in the years of our boyhood. In another year we shall most likely have more in reserve. If we can obtain a supply in the beginning of the week we shall not suffer anything.

We have mentioned *Asparagus* above, as if for growing in a darkish Mushroom house. We do not generally do so, as for roots taken up to force we prefer a box with a slight hotbed beneath it, so that the young shoots may be alike tender and green from the full light enjoyed. But frequently we have had fine Asparagus by placing the roots on heat in a Mushroom house or other dark place, cutting them when of the proper size, then setting them in a saucer with just a little water at the bottom, packed in damp moss for 2 inches of their height, and exposing the top to full light for two or three days in a house averaging from 50° to 55° or 60° in temperature. The tops thus treated become nice and green. It is a mistake in forcing Asparagus to give cold air, or otherwise greatly to cool the grass, even to green it, as such treatment has a tendency to make even very good Asparagus hard and stringy.

FRUIT GARDEN.

We have done little out of doors except frightening birds from the buds of fruit trees, but in bad weather we proceeded with pruning and washing trees and walls in the orchard house, having much of such work still in reserve. We first of all syringe the glass, woodwork, and trees with warm water with a little soap in it, the water averaging 180° to 200°; then we draw the brush or cloth over the glass and woodwork, and syringe again, driving the water as well as we can into every crevice and opening. Such washing we resort to as a means of prevention, as we in general are put to little expense afterwards in the way of destroying insects. We shall have enough of such work and cleaning for many a wet and boisterous day for six weeks.

ORNAMENTAL DEPARTMENT.

In moving tender plants we had to use boxes and baskets covered to carry them through the open air. We have prepared some places for propagating, seed-sowing, and potting. We are furnishing our fruit houses with strong new wooden stages, of which more anon. Houses have been kept low when the weather was dull, and all extra moisture avoided. Camellias and Azaleas coming on had warm water given to them, and all watering was given with water a little warmed. The chief work on the 6th and 7th was washing the glass and walls of corridors. Beautiful as the snow is in its whiteness, it seems to bring with it almost everything that is dirty and smoke-begrimed in the atmosphere. Stone pathways in arcades, the exposed walls of corridors painted of a light colour, and glass at all exposed with flat roofs, all looked as if a sweep's bag had been pulled over them when damp. All were brushed with warmed, weak, soap water, then with clean water, and the stones well scrubbed with sand, and the effect was most cheering.

Even on the score of cleanliness and freedom from soot-encrustations it is of importance in new places so to arrange the houses at once that one chimney at a little distance from the houses, and where it can be concealed, should be used instead of several or many. In old places, where a glass house has been added here and another there on different levels, and on no definite plan, it is difficult and expensive to secure these advantages, and in many cases the disadvantages must be put up with. In a few cases in flat-roofed houses, after the snow has left its distilled matter behind it, some of the outside glass, quite clean in the autumn, looks as if a soot-brush had passed over it. Such matters must wait for the present.—R. F.

TRADE CATALOGUES RECEIVED.

William Paul, Waltham Cross, London, N.—*Select List of Vegetable, Flower, and Farm Seeds, Gladioli, &c.*

Dick Radclyffe & Co., 129, High Holborn, London, W.C.—*Spring Catalogue of Vegetable, Agricultural, and Flower Seeds, &c.*

Arthur Henderson & Co., Pine Apple Place, Maida Vale, London, W. —*Catalogue of Kitchen Garden, Farm, and Flower Seeds.*

TO CORRESPONDENTS.

BOOKS (*Well-wisher*).—You must consult the catalogues of the British Museum for "all" the books on Orchids. You can have the "Orchid Manual" free by post from our office if you enclose thirty-two postage stamps with your address. Williams's "Orchid-Grower's Manual" is 5*s.*, and can be obtained through any bookseller.

GARDENERS' EXAMINATIONS (*G. W. C.*).—Write to James Richards, Esq., Royal Horticultural Society, South Kensington, W., and he will give you the necessary information. Or you may apply to the Secretary of the Society of Arts, Adelphi, and he will inform you the nearest place to you where you can go up for an examination. You can be examined either by the Royal Horticultural Society or the Society of Arts.

VARIOUS (*Thos. Wilson*).—The King Apple of Lancashire and Yorkshire you will find mentioned in Hogg's "Pomology" and "Fruit Manual" under the name of Warner's King. The baking Apple is Toker's Incomparable. The defect which you complain of in the Black Alicante Vine will be remedied by age. We cannot suggest anything better for arresting the extension of the Birch branches than that which you have adopted, except that you might take out some of the longer branches at the same time that you curtail the roots. This might be done without disfiguring the outline of the tree.

PRIZE FOR STRAWBERRIES AT THE OXFORD EXHIBITION (*T. Elcome*).—If the prize was offered by the Royal Horticultural Society, write to Mr. Richards, Assistant Secretary, Royal Horticultural Society's offices, South Kensington, London. If it was a local prize, write to the Secretary of the Oxford Horticultural Society.

TREE-BORING CATERPILLARS (*J. Green*).—They are the larvæ of the Goat Moth (Cossus ligniperda). When the existence of one of these creatures is detected in the trunk of a tree by its excrement, relief comes too late for the tree, even if we are able to kill the caterpillar, the mischief being already done. Notwithstanding this, the caterpillar should never be left undisturbed, and an attempt should be made to reach it by enlarging the opening with a garden knife, or endeavouring to kill it by thrusting a piece of pointed wire up the hole. It is called the Goat Moth from the peculiar smell both of the insect and its larva.

PINE APPLE (*W. Watson*).—Our correspondent wishes for information respecting a variety called Prince Albert, the usual weight, quality, and if best in summer or winter.

GERANIUMS FROSTED (*Novice*).—At present we would only cut away the frosted parts, deferring cutting down until they were beginning to grow; or prune them at the beginning of March, and encourage growth with a gentle heat.

WATERING WITH HOT WATER (*D. M.*).—It is advisable to water plants with water somewhat warmer than the temperature in which they are growing in order to prevent checks, which are apt to result from using water colder than the house. Beyond this there is no advantage in using water warmer than the atmosphere—it stimulates the roots; but watering with warm water may be carried too far, as it is evident that though the hot water may for a time excite the roots to growth, it falls to the temperature of the house, and though not so immediate in its effects, the chill is quite as disastrous as watering with water which is too cold. In a house at 55°, we consider 75° too high a temperature for the water; 55° to 60° would be quite high enough, and in no case would we use water higher by 5° than the mean of the house, or that of the bed the pots may be grown in or on. We have known Pine-Apple plants in a hotbed of tan supplied with water at 65°, whilst the pots were plunged in a hotbed where the temperature at 1 foot deep was 90°, in effect like a fall of snow at midsummer.

FITTONIA ARGYRONEURA SHOOTS DYING (*Idem*).—We think it is caused by the plants being grown in a variable temperature. It may also be a result of cold air in combination with an excess of moisture. Apart from that we consider it is mainly due to the low temperature. The temperature ought to average 60° at this season, and especially as the plant is but young.

TREATMENT OF BEDDING PELARGONIUMS—FORCING BULBS (*A Scotch Gardener*).—We have no doubt your treatment answers your purpose, but we do not see any necessity for first placing three or four plants in a pot, and this month shaking them out and potting singly, then encouraging growth for a few weeks. We think they would be better potted off singly at first, by which means you would save the labour of the first potting and shaking out, which latter is attended with the loss of any newly-formed fibres. We have known a good display of bloom from autumn-struck bedding Geraniums; but we prefer keeping all the old plants we can, as they bloom earlier and more profusely than cuttings of the previous autumn. The treatment of the bulbs could not have been better. For early flowering they should be potted much earlier than the 26th of October; indeed, we would pot in September at the latest for blooming at Christmas and the New Year, and afford them a month, or, better, six weeks to form roots before being introduced into heat. Both Hyacinths and Tulips may be successfully forced from October, but the bulbs must

be potted early, so as to afford time for roots to form before the leaves start into growth. Cinerariae are much injured in a temperature of from 60° to 65°. They can be forced; indeed we have now in a pit at 45° to 50° upwards of a hundred plants that will flower finely next month. They are in 8-inch pots. Of Primulas in a temperature of 60° to 65° we have no experience. Ours are now in fine bloom in a greenhouse at a temperature of 40° to 45°, the highest temperature they require. We know that Geraniums may be packed away in autumn in a cool dry place, but safe from frost; and if potted in March and encouraged with heat and moisture, they will be in good condition by the end of May—quite as good as those wintered in a glass structure. We see nothing in your treatment but what is sound.

Increasing Heat from Hot Water (*H. Foy*).—You cannot do better than as you propose—add another pipe all round, connecting the flow and return with 1-inch piping. Strong pipes may be had with a screw formed at each end; or you may have one screw, and the other end to go firmly into a socket pipe. We have found that by connecting with inch pipe in the mode proposed, if the inch pipe is inserted in the side, and the added pipe is on the same level, the fresh pipe will be scarcely so hot as the first are; but if the inch pipe is inserted near the upper surface, and the fresh pipe is an inch or two higher all round, then the heat will be about equal.

Vines in Pots Injured (*G. B. A.*).—Under the circumstances we would cut the Vines as low as convenient, and let them start naturally the first season, taking one shoot from each. You can give a little extra heat in summer and autumn to ripen the wood earlier.

Gas Extinguished by Down-draught (*S. K.*).—Try suspending a thin sheet of talc or of iron over the gas lights.

Air Circulating in Ice House (*B. H. P.*).—The propriety of air passing through an ice well, or house, would depend on whether the house was empty, and whether the air was warm or frosty. In keen frosty weather free air to the ice house would be an advantage. We prefer dry straw to cover ice, though we seldom use any.

Tax on Gardeners—Heat from Dung (*T. H. T.*).—Every gardener, whether he lives on the premises or not, subjects his employer to a tax on his account. In fact, more than that, according to the celebrated decision in the Duke of Marlborough's case, every old labourer who carries a broom in a garden or pleasure ground, may render his employer liable to a similar tax. This, however, is seldom resorted to in practice, and it would be very hard if gentlemen who kindly employ a number of extra men on their demesnes, when work is scarce in winter, would also be mulcted by a tax on their generosity. Fresh dung merely thrown together into a bed will not keep heat long, but will soon heat itself dry, and especially in such weather as we have lately had. If you turn it over now and add a little more water where dry, it will soon heat itself again. If you cannot do that, then prepare a little more dung, get it hot, and take what you can away from the outside of the old bed, add the fresh, and watch the results. We know of nothing better as a weeping tree exposed to the sea air than a Weeping Willow, or a Weeping Ash, but near Ilfracombe we would try the beautiful Sophora japonica pendula, grafted some 12 or 15 feet from the ground. The wood has a beautiful tinge even when the leaves have fallen. Cupressus macrocarpa planted six years may be transplanted, if care be taken to trace the roots and take it up with a ball of roots. We would, however, defer the operation until the end of March.

Wardian Fern Case (*E. S.*).—We know of no makers but those who advertise in our Journal. Write to Mr. Fox, Arcade, Royal Horticultural Society's Garden, South Kensington. He may give you information.

Cheap Hot-water Apparatus (*Lancashire*).—Thanks, we will ascertain if it is suitable.

Hot-water-heating Failure (*E. C. S.*).—We think that if you will read carefully the article of "R. S.," page 321, October 27th, and the questions and the answers respecting it, at pages 8 and 9 of the current month, you will most probably find out the cause of your want of success. If your boiler is sufficient for double the piping, it still must be rather small, when, though tubular, it can hold only about half a bushel of coke. In such a case we would not use the coke over-large, but break it sufficiently to be close together, but not to make it too small, yet so that the largest pieces should be from the size of eggs to that of walnuts, and the smallest from the size of beans. If you could obtain it we would have half of the coal used by "R. S." The great cause, however, of your failure from the fuel caking, and the fire going out beneath it, we think is owing to the admittance of too much air from the ashpit door. This better attended to, with the last feeding of the furnace pressed down rather firmly, and the help of a damper, would, we think, do away with your troubles. But this will not be the case unless two things be kept in mind and acted on:—First, That every furnace and every boiler, though apparently scores of them seem exactly alike, will each have some little peculiarity, and that peculiarity can only be known by practical observation. Secondly, in adding fuel to a furnace for the last time at night in severe weather, it is well to bear in mind, that the fuel added is less intended to raise the temperature in the house than to keep it from falling over-much. It is, therefore, important to have a good heat before adding the last fuel.

Hot-water Piping Necessary (*W. G.*).—For a span-roofed house 16 feet by 10 feet, we do not think that one 4-inch pipe as a flow, and a similar pipe as a return, would be sufficient to keep up a temperature of 45° in such weather as we have had lately. Such pipes all round would be safer. Much, however, would depend on how near the glass comes to the ground on each side; if within a foot or so of the ground, a third pipe at the side and end would, at least, be necessary, not but that the pipes alluded to would throw off much heat if the water were near the boiling point, but it is always a waste of fuel to make it so hot. Four-inch glazed drain-pipes well cemented at the joints, would do for hot water just as well as iron pipes. In the first house we saw heated by hot water, such pipes were used. It is well to have an iron pipe for at least a yard from the boiler—flow and return. Considering the number of joints, if the pipes are of the usual size, and their greater liability to accidents, they are, on the whole, not equal to iron pipes. As you have them, you might make your two iron pipes, with the exception of that near the bottom of the boiler, flow pipes, let them terminate in an open cistern at the end of the house alluded to, and from that take one or two of the glazed pipes on a lower level as returns. We regret we cannot say more of Bishop's boiler than is stated in the "Heating Manual," and page 134 of the twenty fifth volume of the old series, but the chief advantage of such a boiler consists in its being made by a clever handy man. When that cannot be done, it will generally be better to use a common saddle-back or conical boiler. Boilers may be extremely simple and effective, as Mr Bishop's, but then such boilers can only be made so as to be marketable where there is a good supply for them. Perhaps Mr. Bishop or Mr. Allen may see this, and then give a more definite reply to our correspondent. For houses of all such sizes we consider that hot water is the most expensive mode of heating. Supposing that in this 10-feet span house the pathway is in the middle, then a 6-inch-wide flow and return fine under the pathway, with the furnace at one end outside, would be by far the cheapest and most comfortable mode of heating it. A small iron stove inside, with a flat top for an evaporating-basin, would cost much less than either, but the firing would be more troublesome. However, let everybody have hot water if it so please them. The heat is genial, and there is less likelihood of accidents.

Heating a Portable House (*New Subscriber*).—It is very difficult to secure all that you want, simply and economically, because the place is so small, and all must be portable. The house is 12 feet by 8 feet, the height at back 9 feet, in front 5½ feet, all of 1-inch deal, except the roof and front of glass. A hotbed is wanted for raising seeds, and we are asked our opinion as to a flue, hot-water pipes, and tanks, but all these or any one of them must be portable, and require little attention in stoking, &c. We can hardly see how you could have a portable flue, unless it were an iron one, and the furnace could not well be portable. We do not know how you are situated, but if you could obtain gas easily, a gas-stove and small boiler would be the very thing for you, with a very small pipe leading from the furnace to the open air. (See No. 311, on gas stoves.) With such a stove in the centre of the house in front you could take 2-inch hot-water pipes each way, and the whole of that space you could enclose in a chamber from 18 to 24 inches wide with sheet iron, and set glazed cases over it for propagating, or you could do this, covering in half of the length, leaving the other exposed for heating the house. We have seen plans of gas stoves and boilers by a Messrs. Wright & Co., where the stove is fitted with three lengths of small piping for a space of nearly 5 feet. Now the furnace boiler left exposed, and all the pipe part shut in, would form your bed for seed-raising, &c. There is no plan so simple as gas, where you can have it handy. Another simple plan and portable, would be to have a low, square, flat-headed, iron stove to be fed from either the inside or outside of the house, a space shut in to form a chamber, the top of the chamber to be 2 or 3 inches higher than the top of the stove. The whole space in front may be enclosed for 18 or 20 inches in width; but the greatest heat will be next the stove. We would use stout sheet iron for the top of the chamber, which would thus be the bottom of the hotbed. A few sliding openings in the side of the chamber next the pathway would enable you to regulate the heat of the house as desirable. Once more, suppose you had a small iron stove to heat the house so as to keep your plants safe, and if you do not wish a large propagating-box, and if you are at all near a kitchen boiler, what would you say to this?—viz., a stout wooden box, say from 3 to 4½ feet long, 20 inches wide, and 3 inches deep, set on any suitable height, made waterproof inside, covered on the top securely with plate iron, and furnished with small wooden boxes, say two or three, or all in one piece according to the size of the shallow box, and glazed with a moveable sash, if that should be a single square or frame. There might be a tap at bottom to take out water, and one pipe at the top to be closed with a cork when not wanted, and to admit a funnel when necessary; and by means of a potful of warm water you could regulate the heat in your little propagating-bed to a nicety, by simply drawing off cold water and adding hot water. Twice in the twenty-four hours would generally suffice, so far as heat was concerned.

Mushroom-house Shelves (*N. M.*).—We think you must have missed what has been said as to the material of Mushroom shelves. The rusting of iron was referred to, and ignorance confessed as to how long galvanising would save iron from rusting. Your practice may warrant your preferring wood to slate for shelves, but we must own we never could see much difference as respects the produce, when both have been managed with equal care. Slate gives no harbour to some enemies, as wood does, especially when it begins to decay. The mere extra coldness in a house is of little moment. We use wood ourselves, but we by no means disparage slate.

Vines in Pots (*W. B.*).—We have no doubt that Vines in pots will succeed very well on the top of the back flue in the vinery as you propose; and if the pot stands on a large flat, and the flat on the top of the flue, it would be well to have three pieces of something inside the flat or saucer, for an inch in depth, for the pot to stand upon, and the water in the saucer should never be higher than the bottom of the pot. All watering should be given at the surface, but if more comes into the saucer it should be removed. Such Vines, according to their strength, may be left from 3½ to 5 feet in length. Unless you make an unusually good bargain we have little faith in your doing much with Vines sold at 5*s.* each. Good fruiting Vines in pots require so much care, labour, and room to well ripen the wood, that we think good fruiting plants cannot be had for that money, unless the holder is very anxious to sell. The mode referred to—placing the pots in pans, is not so good as having a box separated from the flue by a brick laid flat, and the box large enough to permit of the pot being plunged in tan or leaves. The giving enough of heat in the flue at the back of the house, to start these Vines now will undoubtedly influence the other Vines in the house and cause them to break sooner in consequence, though not so soon as the Vines in pots. If you wish to keep the house Vines back and get the pot Vines forward, you would require to shut in with glass the pot Vines, and give more than the usual quantity of air to the front of the house. By such means the Vines in pots may be strong before those Vines planted in the house begin to swell. With the house all open you may get the pot Vines to ripen their crops a month earlier than the Vines in the house; but where anything like two crops in one house is desirable it is essential that one part should be shut in, or that the late Vines should be taken out until it is deemed necessary to introduce them.

Labelling Fruit Trees.—"W. R. J." prefers numbering the trees, and having a plan and numbers on it in his pocket, and his gardener having another. This does not facilitate the acquirement of the names by visitors or other members of the family.

Auricula Shows.—"E. R." wishes to know when an Auricula Show is to be held in London or elsewhere.

Fuchsia Father Ignatius (*A Lady in Cheshire*).—It is named as you conjecture. Corolla cup-shaped, indigo, sometimes striped with rose; tube and sepals scarlet. The plant is of compact free-blooming habit.

Hot Water Circulating Downwards—"'Poor Gardener' asks me to explain how hot water will descend 22 feet in 100 feet, and then return to the same point on a level. When I wrote before in reply to 'Poor Gardener's' lamentations I ought to have mentioned that the flow-pipe first rises from the boiler to heat a propagating pit which is much higher than our greenhouse; the same pipe branches off to heat this pit, and continues its downward course to heat the greenhouse. The return-pipe in this greenhouse goes back to the boiler after passing through the bottom of the bed in the propagating pit mentioned above, being quite on a level, but not below the level of the boiler. I may mention that the air-pipe at the elbow of the hot-water pipes at the farthest end from the fall-pipe in the greenhouse has been some time broken off, and I have it plugged up so that only the air-pipe at the top of the fall-pipe is of any service to the piping; still the water circulates freely without the other air-pipe —R. Giddings, *Gardener to W. H. Michael, Esq., Cholmeley Park, Highgate.*"

Cucumber Raising in a Greenhouse (*M. P.*).—Unless you have means of covering the bed in front of your greenhouse with lights, or keep the temperature higher than is required for any greenhouse plant, you cannot raise or grow Cucumbers there. We would cover the space with lights, having a box made about 15 inches high at back, and 9 inches in front or next the walk, and, to cover it, lights hinged at back. It would in that case be a sort of propagating-box, than which nothing is more useful. There should be one in every house. The space for fermenting materials over the flue we would fill with well-sweetened horse dung, as free of straw as possible, but spent hops are good and more lasting than dung. Surely those you used last year were old. Fill quite full of the fermenting material in the first instance, all but space for 6 inches of plunging material, as cinders, cocoa fibre, or sawdust, and in three or four days the bed will be warm. It will be a good place for cuttings and raising from seed plants which need such forwarding.

Old Camellias Sickly (*Camellia*).—We had a lot of similar plants. They had been cut hard and been potted a long time. Early last April we turned them out of the pots, picked away all the old soil we could from amongst the roots, and potted most of the plants afresh in the same size of pot, but some we transferred to larger pots. We used the top inch layer of pasture where the soil was light, and midway between loam and peat, such as is to be had on many commons. It is a soil in which Gorse is plentiful, also Brake and Foxglove where there is shade. This compost was chopped small, and the pots being well cleaned and drained, we put in the plants so that the setting-on of the roots was about half an inch below the rim of the pots. Then we potted, taking care to work the soil well in, and leave no cavities, and the compost was put in rather firmly. The soil was neither wet nor dry. After potting the plants were placed in a vinery, and were syringed twice a-day, and they started into growth very weakly or tardily, but recovered very quickly, and have exceeded our expectations. Though the plants may not have such foliage as we could wish, the leaves of the past year are excellent, both in colour and size, and they are now in splendid bloom. We advise this plan to all who have sickly Camellias. The plan was first broached in this Journal by our esteemed correspondent Mr. Pearson, of Chilwell.

Re-transplanting Roses (*R. S. D.*).—The Roses planted last November may safely be taken up and planted where you require them, either this month or in February, before they begin forming fresh roots. The earlier this work is done the better, the weather being mild and the ground not very wet.

Greenhouse Plants Blighted (*H. L. B.*).—One of the leaves sent us is covered with black fungus, caused by the secretion of some Coccus or scale insect. The remedy is to dip the plants overhead for about a minute in a solution of 3 ozs. of soft soap to the gallon of water, with about twelve drops of spirits of turpentine. Use it at a temperature of 140° for plants that have the wood well ripened, but to those which are partially growing at 125°. The other leaf, which appears to be that of a Myrtle, syringe with the same solution, laying the plant on its side and turning it round, so as to thoroughly wet every part. Keep the solution in all cases from the soil. It is infested with red spider, and we think thrips. To free the leaves of the black fungus, wash them with a sponge and the solution above named. There is no preventive of insects; they come in the best of structures under the care of the most skilful hands.

Gladiolus Treatment (*Idem*).—Except in very sheltered positions, or warm and dry soils, and those inclined to a sandy peat in character, the bulbs should be taken up in autumn as soon as the leaves begin to turn yellow, be dried in a cool airy place, and kept in a cool place, yet safe from frost. Plant them about the middle of March in ground that has been well and deeply dug, exposed to the weather during the winter, and liberally manured. Water freely in dry weather, both overhead and at the roots. We do not take up our bulbs, for our soil just suits them, and they spread and grow in open places in the shrubberies as if they were indigenous. They are, indeed, very hardy, but do not like wet soils. Under this treatment they flower in July and later.

Camellia Buds Falling (*A Young Beginner*).—We think the cause of the buds falling is the roots not supplying sap for the proper expansion of the flowers. In fact, the roots are probably unhealthy, though the evil may be a result of too moist and cold an atmosphere. We advise you to follow the instructions given above.

Plum-tree Roots Diseased (*Celt*).—The roots sent are destroyed by the mycelium of some fungus, the odour of which is very powerful and offensive. We have no doubt it has found its way into the border through using manure, leaf soil, or other material containing the twigs or branches of trees; or it may be that the border was previously occupied with fruit trees, the old roots of which have been left in the ground, and from one or other of those causes the mycelium has found its way to the roots of the young Plum trees. It is doubtful if anything can be done to save the trees from further decay, but we would advise giving the ground a soaking with salt water, 4 ozs. of salt to the gallon of water, making holes so as to admit it more freely to the border. We think your only effectual remedy will be to clear out the trees, remove all the soil that exhibits the "mouldy" appearance, and replace with fresh compost and trees; but we would try the salt solution and free waterings next season. Apply the salt solution between now and March.

Names of Fruits (*J. Bryan*).—Your Apple is Coe's Golden Drop.

Names of Plants (*E. L. J.*).—Zygopetalum Mackayi. (*G. H. W.*).—Lælia anceps. (*Rawlings*).—1, Adiantum formosum; 2, Asplenium Adiantum-nigrum; 3, Asplenium marinum; 4, Platyloma rotundifolia. (*J. R. P.*).—Pittosporum crassifolium, a New Zealand plant, and quite capable of enduring greenhouse treatment. By no means should it be classed as a stove plant. (*A Lady Subscriber*).—Acacia lophantha.

POULTRY, BEE, AND PIGEON CHRONICLE.

CUP FOR LIGHT BRAHMAS.

Having undertaken to get up a subscription cup for the best pen of Light Brahmas at the forthcoming Portsmouth Show, will you permit me, through your columns, to thank those Light Brahma-breeders who have already subscribed, and to make an appeal to other friends of our beautiful and popular breed to lend a helping hand? The sum already promised or paid amounts to £4 7*s*. Two or three additional such subscriptions will complete the requisite amount, and I dare say there are some of your readers who, seeing these lines, will be willing to contribute.

The Portsmouth Show, though of recent origin, promises to be a success, and will combine with her elder sisters, the neighbouring exhibitions, to take away the reproach from the south of England of being behind the northern and midland counties in the number and excellence of poultry shows.—John Pares, *Postford, Guildford.*

COLCHESTER POULTRY SHOW.

Your readers will see in an advertisement that there is to be another poultry show in addition to those that have been announced for the last six months—viz., an exhibition of Poultry, Pigeons, and Rabbits, at Colchester. It would be difficult to arrange a more comprehensive schedule than is issued by the Committee. There are forty-eight classes, comprising twenty-six for fowls (including three for Ducks), with the first prize, £2; the second, £1. Pigeons secure seventeen classes, including a class for the best four pairs of working Antwerps. The war excitement and contingencies have caused us to go back some centuries by using the Carrier Pigeon for the swift dispatch of important messages. It will be well to increase this breed in the same manner as they are increasing our weapons of defence, for both would be found of great service in the event of a war with this country. Whoever has a stocked loft of good Antwerps at such a crisis will realise something handsome. The first prize for Pigeons is £1, the second 10*s*. The great success of the Rabbit Show at York, with 123 entries, and undoubtedly the best collection of Rabbits ever brought together, have induced the Committee to offer £12 in four classes —viz., first prize £2, second £1. There is one class each for Lop-ears, Angoras, Himalayan, and "Any other variety;" a pen to consist of a single Rabbit, either buck or doe. There is a class for dead poultry. In a railway point of view, Colchester is in a good position, being only forty miles from London, and in direct communication, *viâ* Cambridge, with the Great Northern, Midland, and London and North-Western Railways. With these advantages it is to be hoped that aggravating non-arrivals of stock will be avoided.

Another poultry show is talked of in connection with a fat cattle show to be held in Colchester during December. Years ago Colchester had poultry shows with seven hundred entries, when but few towns had any, and there was scarcely any knowledge of the instruction and amusement to be derived from them; it now seems as if it intended to begin again, and to hold its position as one of the originators of this national pastime.—David P. Goodino, *Colchester.*

BRISTOL AND CLIFTON POULTRY SHOW.

This now celebrated Show, on the whole, more than answered our expectations last week; and if the selling classes, which were wanting here, are deducted from the Crystal Palace, it has again maintained its position as having the next largest number of entries of poultry to Birmingham, whilst in point of quality several of the classes were by far the best we have seen during the season. In spite of the late severe weather the birds were mostly in fine order, and the number of empty pens not so great as might have been expected. Of the arrangements we can only say they were as good as usual, this Show being always enviably distinguished for absence of complaints and mischances, while the plan adopted of printing the awards in the margin of the catalogue adds greatly to the convenience of visitors.

DORKINGS.

1. At this Show chickens always come first. Mrs. Wheatley came

to the front with a grand cockerel, again bearing out our remarks on this class at Birmingham. The second and third-prize birds were little behind, and all the prize birds were remarkable for the sound state of the feet. This remark applies to all the Dorking classes, and is the more singular when compared with the tender feet seen at all previous shows. Mr. Martin's bird was not sent.

2. The cup pen contained the very best pullet we think we ever saw, her companion not so good, but would have looked grand anywhere else, and Mr. Patton amused himself and the public by putting £1000 upon this pen. Well, he had a right to be proud of them, though a "cool hundred" used to be thought sufficient to deter purchasers. The second-prize pen was also very good, and Grey, like the first; third, a fair pen, very dark in colour, soon claimed at £10. Both these classes were equal to anything seen this year.

3, 4. Old birds, hardly so good. The first-prize cock was a good bird, a little defective in one foot, but beating easily Mr. Martin's Rose-combed bird, which had evidently had more work than was good for him, though still good enough for the second prize; third fair. The first-prize hens we thought a mistake; they were very dark birds, but not so fine as the Grey second-prize pen. Third again a dark but small pair, and there seems to us to be an evident tendency in the Judges this year to make Dorkings birds of colour. The highly commended pens, 60 and 63, were grand birds, and the hens on the whole were better than the cocks. Except this last class, we thought the Coloured Dorkings remarkably well judged.

5, 6. Silver-Grey cocks were far from equal to those shown at Birmingham, or perhaps London, but the prize birds were fair and well placed. In the hens the prize birds were equal to any yet shown, but the rest only moderate.

7, 8. In White cocks we thought an unnoticed pen, 93, as good as any. First prize very good; second very small; third a large bird, but coarse in comb. The first-prize hens very imperfect in the Dorking toes; second very fair in quality; but the third hardly equal to the highly commended pen 99. Both White classes were very moderate in quality.

COCHINS.

9. Buff cockerels a fair class, but behind Birmingham. The cup pen was a very fine bird, in spite of decided faults, and honestly shown; a little hocked, comb badly serrated, and a little heavy in carriage, but a fine, even, deep gold colour, and shown with all his tail in. Second came a rather clumsy and rather hocked bird, but equal to the average this season; third also hocked, and with a slipped wing, but fine in colour, also too much tail, but shown with it "all there."

10. The pullets, on the other hand, were by far the best class of the season. First-prize rather wanting in shape, and decidedly not equal to the second, which was Lady Gwydyr's old grand pen, and, in spite of a bad match, the best this year. Third pen fine shape, but bad combs, and one a very bad colour on the cushion. The highly commended, 134, was a really good pen, but the high commendation of 138 must have been meant for 139, the colour being very bad, while 139 was fair in every way. Another good pair was disqualified by plucked hocks.

11. First-prize old cock beautiful colour, large and massive; second very good, but a trifle clumsy; third good in colour, but narrow in the saddle, and wretchedly feathered. A middling class.

12. Hens, on the contrary, were a small but very good collection. First a grand pair of light Buffs; second a medium colour, and only inferior in leg-feathering; third well feathered, rather darker; the two highly commended pens also good, and the three prize pens decidedly the best three pens seen together this season.

13. Partridge cockerels a fair class. First a good colour, but bad in every other point, and very small; the third-prize bird worth a dozen of him; but had Mr. Tudman's highly commended pen 170 more leg feather, he would have been better than either. Pen 179 (unnoticed) also a good bird. Second-prize a moderate bird, but in first-rate order. Pen 173 appeared to us to be the same as the first at London, and was probably passed for his hocks.

14. First-prize pullets a grand pair in every way; second bad and streaky, and far worse than Mr. Crossley's, the hocks of which, however, appeared doubtful. Third-prize moderately good in marking, but beautiful in shape, and deserving their place.

15, 16. The first-prize Partridge cock was of very bad carriage, actually drooping to the tail; second-prize far better, but on the whole we preferred the third-prize bird, though coarse in the head. Pen 201 a fine bird, but sadly knocked up, and not fit to show. Of hens there were only four entries. The first took the cup, and was a truly grand pen; second not far off in quality; third middling, one bird having a very coarse head; the fourth pen had one very good bird, but the other spoilt the pen.

17, 18. First and second White cockerels very good; third and the rest not up to the mark, and we thought it a poor class, the Judges thinking the same, only one other pen being noticed. Pullets much better, and the prizes well placed.

19. The first-prize old White bird was very fine in every way, but a little scaly on the feet; second-prize very large, but we liked the third better, in spite of a little yellow.

20. The White hens were the best class of all the Cochins, or of all the year; we were truly glad to see the true old shape, the true old colour, and the true old feather back again. Every pen but one was mentioned, and the prize pens were simply magnificent. It really surprised us to see such a class after what we had seen at the previous shows. Wherever have the birds been to in the meantime?

BRAHMAS.

21. The Dark cockerels were a remarkable collection of forty-five entries. Mr. Moor repeated his Palace success with a bird rather small and low in saddle, but of excellent colour and general shape; second-prize a bird never before exhibited, quite different from the ordinary type of Brahma, standing very tall, and with hardly the accepted tail, but of extraordinary symmetry and grace for so large a bird; the second-prize Birmingham bird came third, the Birmingham cup and many other well-known winners being only highly commended. Altogether the quality of this class was beyond anything we have ever seen.

22. Pullets not so good, but better than at any previous show this season. First-prize, large bird, of fine dark colour, and in good condition, but bad shape, coarse in the head, and mossy in pencilling; second a good pair, one very heavily hocked, but not plucked; third very poor, both in shape and marking, and much worse than several other pens. Pen 322 we thought the best in the class, though only highly commended. Besides the prizes, thirteen pens were noticed by the Judges.

23. The cup was taken by Mrs. Hurt's first-prize cock claimed at Birmingham, which won also at London and Manchester, and in spite of his white tail we thought him well placed; the second was in wretchedly bad condition; third very fine, being the same as took second at Birmingham.

24. The cup was taken by the first-prize Birmingham pen, though only highly commended at Manchester the week before; such is the uncertainty of judging. We liked the second best of all, being grand in shape, but one bird had a tumour on the breast; third a fair pen. This class was very middling.

25, 26, 27, 28. The Light Brahmas were at this Show far behind the Dark in quality. The first and second cockerels were first and second at Birmingham, both small, but of beautiful shape. The first-prize pullets were Mr. Crook's well-known pen; second dirty, but very good; the third contained one very good bird, but the other poor. The cocks looked mostly out of condition. First a fine massive bird of beautiful colour, but very coarse in the head; second very good indeed; third wanting in colour, and very yellow. First-prize hens hardly equal to second, though more showy.

SPANISH.

29. The cockerels were a grand class, and far surpassed all previous collections, though not equal to what we expected owing to the weather. The cup and second were correctly judged, though the cup bird went "all to pieces" next day, which occasioned many remarks on the judging by those who had not seen the cup bird as he was; the third-prize was wry-tailed, which should have disqualified him. The cup Palace pen arrived in bad condition, and was passed over, but picked up wonderfully during the Show. Many other birds were very good.

30. Spanish pullets were a very hard class to judge. On the whole, in spite of much discussion, we thought the awards well placed, but the six highly-commended by no means represented the full merit of the class, which was really wonderful. This was partly owing to the ungalvanised wire fronts of the pens being rather injudiciously oiled, and several of the birds poking their fair heads between the bars paid the penalty of feminine curiosity by showing stains which did not really belong to them.

31, 32. Old cocks were not up to the Bristol standard, owing to the severe weather, only one pen besides the prize hens being commended in a class of eleven. Hens were a small class of six. The first-prize took the cup and were magnificent, the second being not a long way behind; the third only of fair average quality.

FRENCH FOWLS.

33, 34. There was not a single La Flèche cock in the French class, and only one pair of hens, which took the third prize and deserved it. The first and third-prize cocks were Crêve-Cœurs, and we thought the third best. The second was a Houdan, and in his right place. The first-prize hens were also Crêve-Cœurs, and the second Houdans. These classes were not of remarkable merit, and, with perhaps the exception named, were certainly well judged.

HAMBURGHS.

35, 36. Nearly all the Hamburgh classes were a treat to inspect. Gold-spangled were very thickly commended, and deservedly so. The cocks were well placed. We remarked with regret in this class several combs which had evidently had the razor across them. In hens, the first were very neat and almost too dark on the breast, but it must be considered they were shown genuine. Second beautifully marked, but not a perfect match. Third middling in quality, but shown in splendid condition.

37, 38. As a class, the Silver-spangled were not equal to the Gold, though in both classes the cups went to this breed. Cup cock a beautiful tail and breast, but not perfect in bars. Second a little clouded in tail, but a good bird; still, in every point, we thought him inferior to the third. The one highly-commended bird was also very good. The prize hens were all good, and Mr. Howe's highly-commended pen, 616, was well worthy an extra prize.

39, 40. The cup Gold-pencilled cock was a beautiful bird, with the

defined dark tail so needful for pullet-breeding. Second almost if not quite as good. Third much more bronzed, but with nice carriage. We remarked many other bronze tails, to which the pullets owe their failing colour. Pen 640 was a beautiful bird, and ought to have been highly commended instead of simply commended. The cups hens were dense black in the marking, and the second little worse. Third a middling pen, but in fine order. Pen 649 better in colour than either, but small and out of condition. Pen 652 one exquisite bird, but the other poor. Pen 661 one of the best marked in the class, but one hen had an immense overgrown comb, which spoilt the pair.

41, 42. In Silver-pencilled the first-prize cock was a small bird, but good in comb and tail; the third better than the second in every point except tail, which was mossy. Hens were better than usual of late, and the prize pens well placed.

43, 44. Black cocks as good as ever, and the winners rightly selected, several competitors at recent shows losing through want of condition. Black hens won the cup, and were a perfect pair in splendid order. Second and third also good, and not a bad pen in the class; but we never remember seeing a pair quite equal to the winners.

GAME.

44, 46. Cup Black Red cock a fine bird, perhaps a trifle heavy. Second rather dark in colour, but we almost liked him the better. Another unnoticed pen of the same exhibitor ought to have been at least highly commended. Third rather small, but a model in shape. A highly-commended pen, 715, was a beautiful bird in all but his sharp Malay shoulders, which also disfigured many other birds in this class. The hen awards were much discussed, but we thought them pretty fair, changing our own opinion after handling one of the birds, which looked rather soft, but was just the contrary. Mr. Matthews's unnoticed pen, 751, was, however, one that ought to have been highly commended.

47, 48. The cup Brown Red cock was a "clear case" as to his merit, but very short of hackle. Second a very large bird—too large, but good figure nevertheless. Third middling; and the highly commended pen, 763, must have taken his place, but the comb was badly dubbed and had grown again. Hens were barely an average, except the prize birds, which well kept up the old standard. We noticed, however, that most of the birds are getting too red in the face, which is a pity.

49, 50. Duckwing cocks a small but unusually good class, several very good birds being passed over, probably for severe trimming. The third-prize bird was in the best condition decidedly, and many thought should have stood first, but all three were so good there was little to complain of. Hens not so good in our opinion, and we did not thoroughly like any but the prize and the commended pen, 810.

51, 52. In the "Any variety," all the prize-winners were Piles. First-prize cock a beautiful bird. Second not a good colour; and third decidedly too big. Hens were also on the large scale, all but the third prize, which we liked best, being a hard bird of beautiful proportions, and with a true Game head and carriage. Both these classes were decidedly poor.

POLISH.

53, 54. The cup and second-prize Polish cocks were good Silvers; the third a Black. The highly commended pen 842 was a fine Gold bird; we regretted not to see it in the list. The cup hens were also Silver; second an unusually good pair of Golds; and third again a neat pair of Blacks. The hens were a really beautiful class; the cocks hardly so good.

ANY VARIETY.

55, 56. In the Any variety class for cocks Mr. Hinton topped the list with a fine Malay; second was a handsome Sultan, and third Malay again. A Scotch Dumpy only was highly commended, and a Black Cochin commended; all the rest—Andalusians (good), Cuckoo Dorkings, and a Dominique being passed over. In hens Minorcas were first, Dominiques second (a very good award, as being a new breed in England), and a nice little pair of Pekin Bantams third. We think the last is the first pair of Pekin hens ever shown together.

DUCKS.

57—60. Aylesbury Ducks were fair and no more; Rouens a fine class, and several pens changed hands. Blacks mustered eleven pens, and on the whole seem getting a little smaller, which is well; the first-prize pen was exquisite both in shape and plumage. The Any variety class, as usual now, consisted mainly of Mandarins and Carolinas, and the whole class was specially highly commended by the Judges. The third prize, however, went to a nicely marked pair of Sheldrakes.

GEESE AND TURKEYS.

61, 62. Geese were up to the Birmingham standard, and the best collection ever sent to Bristol. The first and second were white, the third Grey. Between the cup and second-prize Turkeys was a very close shave, and the Judges finally changed their first opinion, and gave the cup to the celebrated American bird sent to Birmingham by Mr. Simpson. He has certainly gone very shaky in his legs and feet, but we still think the cup rightly given.

BANTAMS.

63, 64, 65. The first-prize pen had a beautiful cock but only fair hens; second, exquisite hens but an inferior cock; third, not so good as several others; and pen 1011 ought to be at least highly commended. Brown Reds were poor in numbers and quality as a whole, but the cup pen was really exquisite as to colour, carriage, and condition. In the class for Any other variety of Game first and second came Duckwings, and third a beautifully shaped, but, as regards the hens, not over-well-matched pen of Piles.

66, 67, 68. Sebrights, a small but beautiful class, every pen but one being mentioned. The first and second were, however, a long way ahead. Blacks were the best of all the Bantam classes, so much so that one of the Judges promised a cup for them next year. All the prizes were in their place, the first being very good, second rather a large cock, but good in head and carriage. Mr. Cambridge's best pen, containing the best cock we ever saw, has never recovered his visit to the Palace, and before Saturday had to be removed to save his life. Third also a nice pen. Whites a middling class, all but the winners, which were good.

69. In Game Bantam single cocks, the first prize left nothing to complain of; but certainly the next best, if not the very best, in the class, was passed by altogether, being the winner at both Birmingham and London. It may have been on account of the sickle which was so disgracefully abstracted at Birmingham; if so, we can only say that disqualification for such a cause is the way to drive exhibitors into inserting new tails. Second and third both rather poor, and up to the last day of the Show the latter had not been claimed at two guineas.

The total number of entries was 1308, or just one more than at Manchester. The average quality may be partly gathered from the unusual amount of sales, which exceeded £300 in actual cash paid over, and included Mrs. Arkwright's third-prize Dorking pullets at £10; third-prize Dorking cock, £5; Mr. Heath's first-prize Buff pullets, £10 10s.; Mr. Ensor's first-prize Dark Brahma pullets at £20; Mr. L. Wright's commended pair ditto at £10; Mr. Curzon's Dark cock at £15 15s.; Mr. Morrell's second-prize Dark hens, £10; Mr. Beldon's cup Gold-pencilled cock at £6 6s., and his first-prize hens at the same price; Mrs. Seamons's Aylesbury Ducks at £5 5s.; and the cup Black Red Bantams at £10 10s.

Mr. Hewitt was to have been one of the Judges, but his sudden illness necessitated some revision of the intended arrangements, and gave the remaining three Judges rather hard work. Mr. Teebay judged the Brahmas, Spanish, Game, and Game Bantams; Mr. Teebay and Mr. Dixon the Hamburghs; and the Rev. G. Hodgson and Mr. Dixon the remaining classes, while the Pigeons were judged by Mr. T. J. Cottle, of Cheltenham.

The weather throughout was very bad, but we trust the heavy sales will to some extent make up for this drawback to the attendance.

Dorkings (Coloured).—*Cockerel.*—1, 3, and Cup, Mrs. E. Wheatley, Ingatestone. 2, L. Patton, Hillmore, Taunton. *hc*, Mrs. Arkwright, Sutton Scarsdale, Chesterfield; R. W. Beachey, Kingskerswell (2); L. Patton; R. C. Forster, Bath; W. W. Ruttlidge, Kendal. *c*, Mrs. Hind, Kendal.

Dorkings (Coloured).—*Pullets.*—1 and Cup, L. Patton. 2, Mrs. E. Wheatley. 3, Mrs. Arkwright. *hc*, G. J. Mitchell, Burton-on-Trent (2); L. Patton; R. Smalley, Lancaster.

Dorkings (Coloured).—*Cock.*—1, L. Patton. 2, J. Martin, Worcester. 3, Rev. J. D. Hoysted, Bradenstoke, Chippenham. *hc*, Mrs. M. D. Dunn, Hungerford. *c*, S. H. Stott, Rochdale.

Dorkings (Colonred).—*Hens.*—1, R. W. Beachey. 2, L. Patton. 3, Mrs. Arkwright. *hc*, Henry Lingwood, Barking, Needham Market; L. Patton (2); J. White, Warlaby, Northallerton. *c*, Rev. J. D. Hoysted.

Dorkings (Silver-Grey).—*Cockerel or Cock.*—1, O. E. Cresswell, Hanworth Rectory. 2, Hon. J. Massey, Limerick. 3 W. E. George, Stoke Bishop, Bristol. *hc*, Hon. H. Fitzwilliam, Wentworth Woodhouse; J. Longland, Grendon, Northampton.

Dorkings (Silver-Grey).—*Pullets or Hens.*—1, O. E. Cresswell. 2, W. W. Ruttlidge. 3, W. H. Denison. *hc*, W. E. George (2). *c*, J. Longland.

Dorkings (White).—*Cockerel or Cock.*—1, Miss Fairhurst, Ormskirk. 2, E. Williams, Henllys, Berriew. 3, J. Choyce, Atherstone.

Dorkings (White).—*Pullets or Hens.*—1, Mrs. M. A. Hayne, Fordington, Dorchester. 2 and *hc*, J. Choyce. 3, Mrs. Hartnell, Bridgewater.

Cochins (Cinnamon and Buff).—*Cockerel.*—1 and Cup, Lady Gwydyr, Stoke Park, Ipswich. 2, Mrs. Wilkin, Bootle. 3, H. Lloyd, jun. *hc*, W. A. Taylor, Manchester; Mrs. Wilkin; J. Watts, King's Heath; D. Young, Leamington; Mrs. P. V. M. Filleul, Weston-super-Mare. *c*, Mrs. Allsopp, Hindlip, Worcester; J. Dawes, Birmingham.

Cochins (Cinnamon and Buff).—*Pullets.*—1, G. Heath. 2, Lady Gwydyr. 3, L. Patton. *hc*, W. A. Taylor; Miss J. Milward, Newton St. Loe, Bristol; C. Bloodworth, Cheltenham. *c*, Henry Lingwood; A. Darby, Bridgnorth.

Cochins (Cinnamon and Buff).—*Cock.*—1, W. A. Taylor. 2, C. Felton, Birmingham. 3, R. Dawson, Beverley. *hc*, W. A. Burnell, Southwell (2); Mrs. Wilkin; J. Watts; Henry Lingwood; E. Thomas, Didsbury.

Cochins (Cinnamon and Buff).—*Hens.*—1, W. A. Burnell. 2, W. A. Taylor. 3, C. Felton. *hc*, J. Watts; A. Darby.

Cochins (Brown and Partridge).—*Cockerel.*—1, C. F. Wilson, Totton. 2, W. A. Taylor. 3, E. Leech. *hc*, E. Tudman, Whitchurch, Salop; G. Lamb, Compton, Wolverhampton. *c*, J. K. Fowler, Aylesbury; J. Stephens, Walsall.

Cochins (Brown and Partridge).—*Pullets.*—1, W. A. Taylor. 2, G. Lamb. 3, S. Stretch, Ormskirk.

Cochins (Brown and Partridge).—*Cock.*—1, T. M. Derry, Godney. 2, E. Tudman. 3, W. A. Taylor. *hc*, Mrs. R. White, Sheffield; J. Bloodworth.

Cochins (Brown and Partridge).—*Hens.*—1 and Cup, W. A. Taylor. 2, E. Tudman. 3, J. Stephens.

Cochins (White).—*Cockerel.*—1, Mrs. A. Williamson, Leicester. 2, E. Fearon, Whitehaven. 3, Miss E. A. Stephens, Dublin. *hc*, J. Bloodworth.

Cochins (White).—*Pullets.*—1, R. Smalley. 2, G. Shrimpton. 3, R. Chase, Wylde Green, Birmingham. *hc*, R. Chase; Mrs. A. Williamson; R. S. S. Woodgate. *c*, G. Shrimpton, Leighton Buzzard; J. Weeks, Bootle.

Cochins (White).—*Cock.*—1, A. J. E. Swindell, Kniver, Stourbridge. 2, W. E. George. 3, J. Sichel. *hc*, R. Smalley.

Cochins (White).—*Hens.*—1, G. Shrimpton. 2, J. Sichel. 3, R. Smalley. *hc*, W. E. George; E. Fearon; F. Brewer. *c*, S. Felgate, Ipswich.

Brahmas (Dark).—*Cockerel.*—1, H. P. Moor, Langley Burrell. 2, L. Wright, Bristol. 3, W. Adams, Ipswich. *hc*, A. O. Worthington, Burton-on-Trent; J. Kingdon, Calne; T. F. Ansdell, St. Helen's; J. H. Pickles, Birkdale, Southport; R. Brownlie, Kirkcaldy; W. Hargreaves, Bacup; Hon. Miss D. Pennant, Penrhyn Castle, Bangor; H. Lacy, Hebden Bridge; O. Claypole, Stoke Bishop. *c*, Rev. J. J. Evans, Brecon; A. O. Worthington; H. Ferris, Cleeve.

Brahmas (Dark).—*Pullets.*—1, E. Ensor, Bristol. 2, Lady Gwydyr. 3, Mrs Hurt, Alderwasley, Derby. *hc*, H. B. Morrell, Clyro; Rev. J. Bowen, Treffgarne; Lady Gwydyr; H. B. Morrell; L. Wright (2); Mrs. S. Vigor, Uxbridge; J. Watts; W. Whittaker, Belper; H. Lacy; J. K. Fowler. *c*, W. Whiteley, Sheffield; T. Pomfret, Preston.

BRAHMAS (Dark).—*Cock.*—1 and Cup, Hon. Mrs. A. B. Hamilton, Woburn. 2, H. Lacy. 3, Horace Lingwood, Creeting, Needham Market. *hc*, Rev. J. Bowen; J. Dawes; L. Wright; J. S. Tainton, Gloucester; E. Ensor; W. Whittaker; Hon. Miss D. Pennant.

BRAHMAS (Dark).—*Hens.*—1 and Cup, T. F. Ansdell. 2, H. B. Morrell. 3, Mrs. Hurt. *hc*, Rev. J. Bowen; Horace Lingwood; W. Gamon; J. Watts; H. Lacy.

BRAHMAS (Light).—*Cockerel.*—1, M. Leno. 2, W. T. Storer, Brewood. 3, H. M. Maynard, Holmewood, Isle of Wight. *hc*, A. O. Worthington; J. Watts; W. T. Storer; F. Crook; J. R. Rodbard, Wrington, Bristol. *c*, H. M. Maynard.

BRAHMAS (Light).—*Pullets.*—1, F. Crook. 2, T. A. Dean, Moreton-on-Lugg. A. O. Worthington. *hc*, C. F. Wilson; E. Hoare, Wolston (2); J. Watts; J. Bloodworth; Mrs. S. Vigor.

BRAHMAS (Light).—*Cock.*—1, Mrs. A. Williamson. 2, H. Dowsett, Plesbey, Chelmsford. 3, H. M. Maynard. *hc*, F. Crook, Forest Hill; W. J. Craddock, Maindee, Newport, Mon.

BRAHMAS (Light).—*Hens.*—1, J. R. Rodbard. 2, F. Crook. 3, H. M. Maynard. *hc*, A. O. Worthington; Mrs. A. Williamson. *c*, J. Pares, Pestford, Guildford.

SPANISH.—*Cockerel.*—1 and Cup, F. James, Peckham Rye. 2, E. Jones, Clifton. 3, Mrs. Allsopp. *hc*, E. Jones (3); Boulton & Gliddon, Bristol; G. Tonkin, Bristol; J. Barry, Totterdown, Bristol. *c*, Boulton & Gliddon.

SPANISH.—*Pullets.*—1 and *c*, E. Jones. 2, H. Lane, Bristol. 3, T. Bamfield, Brandon Hill, Bristol. *hc*, Boulton & Gliddon; Miss E. Browne; E. Jones (2); J. R. Rodbard; T. Bush, Cleeve, Bristol.

SPANISH.—*Cock.*—1 and 2, H. Lane. 3, Miss E. Browne, Chard. *c*, Mrs. Allsopp.

SPANISH.—*Hens.*—1 and Cup, T. Bamfield. 2, H. Lane. 3, Hon. Miss D. Pennant. *c*, J. R. Rodbard.

FRENCH FOWLS.—*Cockerel or Cock.*—1, W. O. Quibell, Newark (Crève-Cœur). 2, R. B. Wood, Uttoxeter (Houdan). 3, W. R. Park, Melrose (Crève-Cœur). *hc*, C. H. Smith, Radcliffe-on-Treut (Crève-Cœur); Rev. J. Richardson, Sandy (Crève-Cœur); W. Tippler, Chelmsford; W. Boutcher, Notting Hill (Crève-Cœur); W. O. Quibell (Houdan).

FRENCH FOWLS.—*Pullets or Hens.*—1, W. R. Park (Crève-Cœur). 2, Hills and Co., Brighton (Houdan). 3, Hon. C. W. Fitzwilliam (La Flèche) *hc*, H. Wyndham, Brockhampton, Worcester (Creve-Cœur); W. O. Quibell (Crève-Cœur); J. K. Fowler.

HAMBURGHS (Gold-spangled).—*Cockerel or Cock.*—1, W. Driver, Keighley. 2, H. Beldon, Goitstock, Bingley. 3, J. Buckley, Taunton, Ashtou-under-Lyne. *hc*, W. de Winton, Durdham Down, Bristol; J. Medway, Newton Abbott; T. Mayo, Wolverhampton; Miss C. E. Palmer, Lighthorne, Warwick; W. A. Hyde, Ashton-under-Lyne; J. H. Macnab, Barrhead. *c*, C. Bloodworth.

HAMBURGHS (Gold-spangled).—*Pullets or Hens.*—1, J. Buckley. 2, J. Ogden. 3, W. de Winton. *hc*, W. Driver; J. Ogden, Hollinwood; H. Beldon; Mrs. J. Pattison. *c*, C. Parsons, Wolverhampton; W. A. Hyde.

HAMBURGHS (Silver-spangled).—*Cockerel or Cock.*—1 and Cup, H. Beldon. 2, Miss E. Browne. 3, J. H. Howe. *hc*, N. Barter, Plymouth. *c*, Miss E. Browne; J. Newick, Taunton.

HAMBURGHS (Silver-spangled).—*Pullets or Hens.*—1 and Cup, H. Beldon. 2, J. Newton, Silsden, Leeds. 3, G. C. Holt, Lawton. *hc*, Miss E. Browne; J. H. Howe, Denton; H. Pickles, jun., Earby.

HAMBURGHS (Gold-pencilled).—*Cockerel or Cock.*—1 and Cup, H. Beldon. 2, W. R. Park. 3, F. Pittis, jun., Newport House, Isle of Wight. *hc*, Rev. A. L. Willett; N. Barter; B. Bee, Goosnargh; F. Pittis; J. Preston, Allerton, Bradford. *c*, J. Walker, Ripley; H. H. Tompson.

HAMBURGHS (Gold-pencilled).—*Pullets or Hens.*—1, H. Beldon. 2, J. Walker. 3, J. K. Fowler. *hc*, F. Pittis; R. R. Parker, Ipswich. *c*, J. Preston.

HAMBURGHS (Silver-pencilled).—*Cockerel or Cock.*—1, H. Pickles, jun. 2, J. Bairstow, Fearncliffe, Bingley. 3, H. Beldon. *hc*, H. Smith, Moreton Banks, Keighley.

HAMBURGHS (Silver-pencilled).—*Pullets or Hens.*—1, H. Pickles, jun. 2, J. Bairstow. 3, N. Barter. *c*, J. Walker.

HAMBURGHS (Black).—*Cockerel or Cock.*—1, N. Marlor, Deuton. 2, Rev. W. Serjeantson, Acton Burnell. 3, W. A. Taylor. *hc*, Hon. and Rev. F. Dutton, Burford.

HAMBURGHS (Black).—*Pullets or Hens* —1 and Cup, Rev. W. Serjeantson. 2, N. Marlor. 3, Hon. and Rev. F. Dutton. *hc*, C. Sidgwick, Keighley; J. M. Kilvert, Wem.

GAME (Black-breasted Reds).—*Cockerel or Cock.*—1 and Cup, S. Beighton, Farnsfield, Southwell. 2, J. Forsyth, Wolverhampton. 3, W. H. Stagg, Netheravon. *hc*, C. H. Ames, Henley; J. Frith; S. Beighton. *c*, T. Mason, Green Ayre, Lancaster.

GAME (Black-breasted Reds).—*Pullet or Hen.*—1, J. Laming. 2, W. J. Pope. 3, W. H. Stagg. *hc*, W. J. Pope, Biggleswade (2); W. H. Stagg (2); W. Boyes. *c*, J. Laming, Cowhurn, Spalding; Mrs. Arkwright.

GAME (Brown-breasted Reds).—*Cockerel or Cock.*—1 and Cup, W. Boyes. 2, J. Laming. 3, W. Sowerbutts, Nantwich. *hc*, J. Laming; G. Doubleday, Upton, Southwell; T. Mason; G. Lunt, Market Drayton; J. W. Jones, Newport, Monmouthshire.

GAME (Brown-breasted Reds).—*Pullet or Hen.*—1 and Cup, S. Matthew, Stowmarket. 2, W. Boyes. 3, T. Burgess, Burleydam. *hc*, W. Perrin, Bristol; W. Sowerbutts.

GAME (Duckwings and other Greys and Blues).—*Cockerel or Cock.*—1, S. Matthew. 2, J. Laming. 3, J. Frith, Chatsworth. *hc*, W. Boyes; J. Laming.

GAME (Duckwings and other Greys and Blues).—*Pullet or Hen.*—1, W. Boyes. 2, E. Bell. 3, T. West. *hc*, W. H. L. Clare, Try Cross, Atherstone. *c*, J. Laming; J. Jeken, Eltham.

GAME (Any other variety).—*Cockerel or Cock.*—1, J. Frith (Pile). 2, H. C. and W. J. Mason (Pile). 3, S. Matthew (Pile). *hc*, J. Tiley; J. Laming; E. Holland.

GAME (Any other variety).—*Pullet or Hen.*—1 and 3, J. Frith. 2, Rev. G. S. Cruwys, Cruwys Morchard, Tiverton. *hc*, G. Lunt (Pile); W. H. L. Clare.

GAME BANTAMS (Black-breasted Reds).—1 and Cup, E. Payne, Cardiff. 2, J. W. Morris. 3, Williams & Straw, Farnsfield, Southwell. *hc*, Miss E. S. Cornwall, Wotton-under-Edge; J. H. Nicholls, Lostwithiel; J. R. Robinson, Sunderland; R. Brownlie.

GAME BANTAMS (Brown-breasted Reds).—1 and Cup, T. C. & E. Newbitt, Epworth. 2, W. Adams. 3, H. Shumach.

GAME BANTAMS (Any other variety).—1, H. Shumach. 2 and *hc*, T. C. & E. Newhitt. 3, J. Eaton, Southwell (Pile).

GAME BANTAMS (Any variety).—*Cock.*—1 and Cup, J. R. Robinson. 2, Mrs. H. Tongue, Farnsfield, Southwell. 3, H. P. Leech. *hc*, J. W. Morris, Rochdale; T. Davies, Bristol; Mrs. E. Crawford, Farnsfield; J. H. Howe; J. H. Glossop, jun., Weston-super-Mare.

BANTAMS (Gold and Silver Sebrights).—1, 2, and Cup, M. Leno, Markyate Street. 3, J. Watts. *hc*, J. Watts; B. C. Greenhill, Bridgewater; Rev. G. S. Cruwys.

BANTAMS (Black Clean-legged).—1, J. Walker. 2, E. Cambridge, Bristol. 3, J. Walker. *hc*, Mrs. T. Bush, Bristol; W. A. Taylor; H. M. Maynard, Holmewood, Isle of Wight; H. Beldon, Goitstock; T. Davies; H. Pickles, jun.

BANTAMS (White Clean-legged).—1 and 2, S. & R. Ashton, Mottram. 3, Rev. F. Tearle, Gazeley Vicarage, Newmarket.

POLISH (Any variety).—*Cockerel or Cock.*—1, 2, and Cup, G. C. Adkins, Birmingham. 3, D. Mutton, Brighton (White Crest). *hc*, M. Nicholls, Peel, Isle of Man; W. Gamon, Chester; G. C. Adkins; H. Beldon; T. Dean.

POLISH (Any variety).—*Pullets or Hens.*—1 and Cup, G. C. Adkins. 2, H. Beldon. 3, Mrs. J. M. Proctor, Hull. *hc*, Mrs. J. M. Proctor; J. Hinton, Warminster; G. C. Adkins (2).

ANY OTHER VARIETY.—*Cockerel or Cock.*—1, J. Hinton. 2, Mrs. Llewellyn, Bridgend (Sultans). 3, S. Rooth, Chesterfield (Malay). *hc*, Miss C. E. Palmer (Scotch Dumpies). *c*, R. Hawkins, Bristol (Andalusian); F. Wilton (Black Cochin).

ANY OTHER VARIETY.—*Pullets or Hens.*—1, J. W. Brown, Bristol (Black Minorcas). 2, J. Whittaker (Dominiques). 3, H. Beldon. *hc*, Lady Gwydyr (Silkies); Mrs. Llewellyn (Sultans); J. Watts. *c*, W. B. Payne, Shrewsbury (Malay).

DUCKS (White Aylesbury).—1, E. Leech, Rochdale. 2, J. K. Fowler, Aylesbury. 3, Mrs. M. Seamons, Aylesbury. *hc*, Lady Gwydyr.

DUCKS (Rouen).—1 and Cup, L. Patton. 2, W. Gamon. 3, S. H. Stott. *hc*, H. B. Smith, Broughton, Preston; L. Patton (2); J. N. C. Pope, Stoke Bishop; J. K. Fowler.

DUCKS (Black East Indian).—1 and Cup, S. Burn, Whitby. 2 and *hc*, W. E. George. 3, Rev. W. Serjeantson.

DUCKS (Any other variety).—1, S. Burn (Mandarin). 2 and 3, H. B. Smith (Carolinas and Sheldrake). Whole class highly commended.

GEESE (Any variety).—1 and Cup, Rev. G. Hustler, Stillingfleet Vicarage, York (White). 2, Mrs. M. Seamons. 3, S. H. Stott. *hc*, J. Baily, jun., Mount Street, London (Bernicle, Egyptian, and Toulouse) (3); C. Homfray, Glen Usk, Caerleon (Spanish); J. K. Fowler.

TURKEYS (Any variety).—1 and Cup, F. Lythall, Banbury (American and Cambridge. 2, L. Patton. 3, Rev. N. J. Ridley. *hc*, L. Patton; Miss J. Millward (Cambridge).

PIGEONS.

CARRIERS (Blue or White).—1 and Cup, J. Watts. *vhc*, J. C. Ord, Pimlico. *hc*, R. Fulton, Deptford.

CARRIERS (Black or Dun).—1 and Cup, E. Horner, Harewood. 2 and *hc*, R. Fulton. *vhc*, F. T. Wiltshire, Croydon (Black); G. S. Hockey; H. Yardley, Birmingham.

POUTERS.—*Cocks.*—1, 2, and Cup, F. Gresham, Strefford. *vhc*, R. Fulton. *c*, R. P. Moon, Driffield. *Hens.*—1, F. Gresham. 2 and *c*, R. Fulton. *hc*, E. T. Dew, Weston-super-Mare (Blue).

TUMBLERS (Almond).—1 and 2, R. Fulton. *vhc*, F. T. Wiltshire (2); J. Ford, Monkwell Street, London. *c*, E. T. Dew.

JACOBINS.—1, R. Fulton. 2, E. Horner. *c*, W. B. Van Haansbergen, Newcastle-on-Tyne; R. Fulton.

BARBS.—1 and Cup, R. Fulton. 2, J. Fielding, jun., Rochdale. *hc*, J. C. Ord J. Baily & Son, Mount Street, London. *c*, E. Horner.

TUMBLERS (Any other variety).—1, J. Ford. 2, R. Fulton. *c*, J. Fielding, jun.

FANTAILS.—1 and Cup, C. Bulpin, Bridgewater. 2, J. F. Loversidge, Newark. *vhc*, J. Elgar, Newark. *c*, J. Baily & Son.

TRUMPETERS.—1, P. H. Jones, Fulham. 2, E. Horner. *hc*, C. Bulpin.

OWLS (English).—1, P. H. Jones. 2, C. Bulpin.

NUNS.—1, T. A. Dean. 2, C. Bulpin.

TURBITS.—1, G. South. 2, E. T. Dew. *hc*, T. Waddington, Feniscowles, Blackburn. *c*, O. E. Cresswell, Hanworth Rectory; G. H. Gregory, Taunton; J. Fielding, jun.; H. Yardley.

DRAGOONS.—1, J. Holland, Manchester. 2, W. Bishop, Dorchester. *vhc*, G. South. *hc*, J. Watts. *c*, W. W. Grainger, Clifton; W. H. Mitchell; H. Yardley.

ANTWERPS.—1, E. Horner. 2, C. Bulpin. *hc*, H. Yardley. *c*, C. F. Copeman, Birmingham.

ANY OTHER VARIETY.—1, J. Bowes, Herne Bay (Archangels). 2, H. Yardley. *vhc*, E. Horner; S. A. Wyllie, East Moulsey (Runts). *c*, T. Waddington.

KIRKCALDY POULTRY AND CANARY SHOW.

THE Fife and Kinross Ornithological Society held its twentieth annual Show in the Corn Exchange, Kirkcaldy, on the 2nd and 3rd inst. Year by year these exhibitions have been steadily increasing in the number of birds shown, and improving in the quality of the stock brought forward. The entries this year considerably exceeded those of any former year. The list of exhibitors embraced most of our Scotch breeders, whose names are now widely known, as well as many prominent English prizetakers, the Emerald Isle also contributing her quota. A noticeable feature in the classes is the increase of Pigeons and the decrease of Canaries, there being a larger number of the former and a smaller number of the latter than at any former show. Brahmas, too, have of late years been superseding Dorkings, but we were glad to observe an increase in the number of Dorking pens this year.

Game and Game *Bantams* were the largest classes exhibited. Fife was famous for her fighting Game in the days of yore, and now that exhibiting has taken the place of fighting she is not behind her former self. There were fifty-eight pens of Game, eighty-three of Game Bantams, and in all the classes of these the quality of the birds was excellent. The competition was a close one, and the Judge must have had some trouble in making his awards. There was not a bad pen in the Hall, and had "YORKSHIRE," who criticised the Game at Leeds, been here, he would have found all the essential characteristics of the breed that he seems to have there missed so much. There was the firm compact body, well-developed muscular thigh, strong bill and snake-like head, with the bold defiant carriage, that give these birds their sprightly bearing. *Dorkings* were more numerous than for some years past, and, in the opinion of the Judge, of finer quality than those shown at Birmingham and Manchester. *Cochins* were on the whole a good class; and the first-prize cockerel shown by Mrs. Oswald, of Dunnikier, is deserving of special notice as a bird of rare excellence. The first-prize hens shown by Mr Green, Belfast, were also very fine. *Brahmas* were a large and good class, the cocks predominating in numbers, but we thought the hens were of better quality. The pair of Mr. Raines, Stirling, which won the cup, were magnificent birds. *Spanish* were a smaller class than usual; the hens taking the cup were in all points excellent birds. *Hamburghs* mustered strongly, Golden-pencilled and Spangled being much superior to the Silver classes. Fowls, "Any other variety," and *Ducks* were both poor classes.

There was a marked improvement since last year in the *Pigeons*. Pouters were a very good class, the silver cup being carried off by a remarkable pair of Whites belonging to Mr. McGill, Elie, who took also the silver cup at the late Edinburgh Columbarian Show with the same cock. Carriers were a more mixed lot, some of them being of considerable merit, others very poor. Fantails showed to more advantage, there being some excellent birds amongst them; good, well-spread, compact tails, with fine carriage and tremulous motion. There would have been a different distribution of prizes, however, had the matching of the pairs been more judicious. Nuns were a good class honestly shown; there had evidently been no tampering with them, but the matching was not in all cases first-rate. Jacobins were an excellent

class, the first-prize particularly so, and none of them bad. Turbits and Owls were on the whole a splendid class. The foreign Owls shown by Mr. Paterson, Melrose, are deserving of special notice, they being very fine birds indeed. Tumblers were a small class and of no particular merit, with the exception of Mr. Yardley's first-prize pair. Barbs were not numerous, and they were generally poor, excepting the first-prize pair belonging to Mr. Yardley. The Any variety class was numerous, varied, and generally very fine.

The north end of the Hall presented a gay appearance with its rows of beautiful singing birds, principally belonging to the "Scotch Fancy," hung in neat cages on a green cloth background.

The Show, altogether, was of a most satisfactory nature, and the arrangements reflect great credit on the managing Committee. It was visited during both days by a large number of people.

GAME.—*Cock.*—Cup, J. W. Will. Errol 2, J. Stark, Crossgates. 3, J. Anderson, Blairgowrie. *hc*, R. Stewart, Kelty, Blairadam; P. Campbell, Old Whatnew Deer. *c*, C. Jamieson, Forfar. *Reds.*—1, R. Stewart. 2 and 3, W. Meldrum, Forfar. *hc*, J. W. Will; J. Stark; J. Wishart, Kirkcaldy; J. H. Herriot, Kirkcaldy; J. Liveston, Forfar. *Chickens.*—1, J. W. Will. 2, W. Meldrum. 3, J. Wishart. *hc*, T. W. Mitchell, Perth; W. Chambers, Leslie; C. Jamieson; J. Liveston; A. Liveston, Forfar. *c*, J. Blair, Dollar. *Any other colour.*—1, Mrs. Harley, Edinburgh. 2, J. W. Will. 3, J. Anderson, Kirkcaldy. *hc*, A. Spalding, Kinginnie, Dundee; H. Geodall. *Chickens.*—1, J. Elder, Kirkcaldy. 2 and 3, J. Anderson.

DORKINGS (Any variety).—*Cock.*—1, D. Gellatly, Meigle. 2, Mrs. Morrison, Stirling. 3, T. Raines, Bridge Haugh, Stirling. *hc*, D. Gellatly; T. Raioes; Mrs. Tullis, Markinch. *c*, D. Annan, Cupar; Mrs. Macdonald, Errol. *Hens.*—1, A. Haggart, Leslie. 2, D. Annan. 3, D. Gellatly. *hc*, D. Gellatly; T. Raines (2); A. Haggart.

COCHIN-CHINA.—*Cock.*—1, Mrs. Oswald, Dunnikier. 2, J. Cowman, Whitehaven. 3, J. H. Dawes, Birmingham. *hc*, A. Williamson, Oxgang, Grangemouth; Mrs. Oswald; J. Cowman; F. H. Green, Windsor, Belfast. *c*, W. Linton, Selkirk. *Hens.*—1, F. H. Green. 2, W. Linton. 3, Mrs. Oswald.

BRAHMA POOTRA.—*Cock.*—1, Mrs. Gillison, Glasgow. 2 and *c*, R. Brownlie, Kirkcaldy. 3, A. Williamson. *hc*, Miss J. Morrison; J. M'Donald; T. Raines. *Hens.*—Cup, T. Raines. 2, Mrs. Gillison. 3, J. Meldrum, Kirkcaldy. *hc*, J. Cowman; F. H. Green, Kirkcaldy; H. Connell.

SPANISH.—*Cock.*—1, J. Soutar, Carnoustie. 2, A. Shepherd, Meigle. 3, R. Somerville, Edinburgh. *Hens.*—Cup, A. Shepherd. 2 and 3, R. Somerville.

HAMBURGHS.—*Spangled.—Cock.*—Cup, J. W. Will. 2 and 3, J. Bell, Cowderbeath. *hc*, W. M. Elder, Leslie. *Hens.*—1, J. W. Will. 2, A. Crosbie, Gattonside, Melrose. 3, R. Dickson, Selkirk. *hc*, Mrs. Harvey; G. Caithness. *Pencilled.—Cock.*—1, J. W. Will. 2, J. M. Campbell, New Byth. 3, W. R. Park, Melrose. *hc*, D. Normand, Kennoway; R. Coupar, Falkland; A. W. Penman, Leslie. *Hens.*—1, A. Pratt, Kirkcaldy. 2, Mrs. Harvey. 3, W. R. Park. *hc*, R. Couper.

GAME BANTAMS.—*Reds—Cock.*—Cup, J. W. Will. 2, Master W. Brownlie, Kirkcaldy. 3, E. Harwood, Accrington. *hc*, Mrs. Abel, Forfar; T. Raines; W. Scott, Jedburgh; J. M. Campbell. *Hens.*—1, Miss N. Brownlie. 2, T. Raines. 3, J. Archibald, Earlston. *hc*, Mrs. Abel; G. Anderson; R. Frew, Kirkcaldy; J. Ross, Pathead. *c*, T. W. Mitchell; G. K. Scobie, Dunfermline. *Any other Colour.—Cock.*—1 and 2, W. Scott. 3, J. Archibald. *hc*, W. Clark, Kirkcaldy; Miss Brownlie; W. Henderson, Kirkcaldy; D. Gillespie. *Hens.*—1, R. Stewart. 2, A. T. Milla, Kirkcaldy. 3, W. Scott.

BANTAMS (Any other variety).—1, Master A. Frew (Silver-laced). 2, H. Yardley, Birmingham. 3, J. Rutherford, Auchtermuchaty.

ANY OTHER VARIETY.—1, W. Paterson, Colinsburgh (Golden Polands). 2, D. Gellatly (Houdans). 3, J. Rutherford (Houdans).

DUCKS (Any variety).—1, R. Dickie, Burnside, Alva. 2, A. Haggart. 3, A. Spalding.

SELLING CLASS (Any variety).—1 and *c*, J. Stoutar (Spanish and Houdans). 2, A. Small, Glasgow (Greys) 3, F. H. Green (Cochins). *hc*, D. Gellatly (Dorkings).

PIGEONS.

POUTERS.—Cup, J. M'Gill, Elie. 2, J. Morrison, Morningside, Edinburgh. 3, J. Grant, Edinburgh. *hc*, W. Rutherford, Edinburgh; H. Bontbron, Edinburgh; J. M'Gill.

CARRIERS.—1, H. Yardley. 2, M'Gill Skinner, Edinburgh. 3, A. Lockbart, Kirkcaldy.

FANTAILS.—1, A. Smith, Broughty Ferry. 2, J. G. Spence, Edinburgh. 3, J. F. Loversidge, Newark. *hc*, A. Lockhart; E. Hope, Kirkcaldy.

TUMBLERS.—1, H. Yardley. 2, F. D. Wood, Edinburgh. 3, J. Bruce, Dunfermline.

NUNS.—1, Miss Drummond, Megginch Castle, Errol. 2, R. Paterson. 3, J. Bell. *hc*, R. Frew. *c*, W. B. Van Haansbergen, Newcastle.

JACOBINS.—1, W. B. Van Haansbergen. 2, H. Yardley. 3, J. G. Spence. *hc*, R. Paterson; T. W. Kilburn; W. B. Van Haansbergen.

TURBITS OR OWLS.—1 and 2, R. Paterson (Owls and Turbits). 3, H. Yardley (Owls). *hc*, J. G. Spence (Owls).

BARBS.—1, H. Yardley. 2 and 3, Withheld.

ANY OTHER VARIETY.—1, W. B. Van Haansbergen (Trumpeters). 2, A. Crosbie (Letz). 3, J. Grant, Edinburgh (Magpies). *hc*, T. Imrie (Archangels); T. W. Kilburn (Frillbacks).

CANARIES.

YELLOW.—*Cocks.*—1, R. Hunter, Longour, Tillicoutry. 2, J. Small, Edinburgh. 3, W. Muirhead, jun., Alloa. *Hen.*—1, J. Hogg, Oakley, Dunfermline. 2, W. Innes, Kirkcaldy. 3, R. Farmer, Kirkcaldy.

BUFF.—*Cock.*—1, G. Spence, Dysart. 2, D. Allan, Leith. 3, J. Hunter, Kirkcaldy. *Hen.*—1, J. Lawson, Dundee. 2 and 3, W. Muirhead, jun.

YELLOW FLECKED.—*Cock.*—1, J. Sime, Grahamstown, Falkirk. 2 and 3, D. Allan. *Hens.*—1, R. Hunter. 2, G. Spence. 3, D. Duncan, Carron.

BUFF FLECKED.—*Cocks.*—1, C. Smith. 2, R. Farmer. 3, R. Brown. *Hens.*—1, J. Lawson. 2, D. Allan.

GOLDFINCH MULES (Yellow or Buff).—1, 2, and 3, J. Robertson, Aberdour.

JUDGES.—*Poultry:* Mr. R. Teebay, Fulwood, Preston. *Pigeons:* Mr. J. Millar, Glasgow. *Canaries:* Mr. J. M'Gill, Elie.

PAISLEY ORNITHOLOGICAL SHOW.

THE seventeenth annual Exhibition was held on the 2nd and 3rd inst., in the Drill Hall, which was closely packed with cages, there being upwards of 1500 birds for competition. The show was admirable. *Game* and *Hamburghs* were present in great numbers. Perhaps there has never been a larger and better exhibition of *Pigeons*. The great interest, however, was centred in the Canary department, in which were 281 entries. Altogether the Show was a great success, and far exceeded those of previous years.

SPANISH.—1, J. Dunlop. 2, A. Walker, Kilmarnock. 3, J. Hamilton, Saltcoats. 4, Miss Rae, Garngad Hill, Glasgow. *hc*, J. M'Innes. *c*, J. Gray, Airdrie. *Chickens.*—1 and Special, A. Yuill, Airdrie. 2, W. Peden, Craighead. 3, W. C. Hardie, Carron. 4, Foster, Green, & Co., Belfast. *hc*, Mrs. Gillison, Milngavie. *c*, J. Hamilton. *Hens.*—1, A. Shiphard, Keggle, Yorkshire. 2, W. C. Hardie. 3, W. Peden. 4, J. M'Innes. *hc*, R. Campbell, Glenfirn. *c*, J. R. Rennards, Helensburgh.

DORKINGS.—1, Mrs. Alston, Craighead. 2, A. Grant, Kilbarchan. 3, A. M'Dougald, Moffat, Airdrie. 4, J. Dollar, Kirkintilloch. *hc*, J. Paul, Glasgow. *Chickens.*—1 and 2, Mrs. Alston. 3 and 4, Z. H. Heys, Springfield, Barrhead. *White.*—1, J. Bell, Dalmellington. 2, R. Farrow, Dalmellington. 3, R. Cron, Dalmellington. 4, Mrs. Tudhope, Meigleriggs. *Hens.*—1, A. M'Donald. 2, R, Campbell. 3, Mrs. Alston. 4, Mrs. Gillison. *hc*, W. Wotherspoon, Castlehead; A. Shiphard.

COCHIN-CHINA —1 and Special, W. Peden. 2, J. H. Green, Belfast. 3, J. Gray. 4, J. Pollock, Bushby. *hc*, H. Paton, Largs.

BRAHMA-POOTRA.—1 and Special, J. H. Green. 2 and Special, Mrs. Gillison. 3, Mrs. Alston. 4, A. Robertson, Kilmarnock. *hc*, R. Abercrombie, Paisley.

SCOTCH.—1, J. Paul. 2, J. Meiklem, Hamilton. 3 and Special, A. Dunlop. 4, J. Kirkpatrick, Waterton, Patna. *c*, R. Cumming, Beith; J. Meiklem.

HAMBURGHS.—*Gold-spangled.*—1 and Special, J. H. M'Nab, Barrhead. 2, R. Mackie, Stewarton. 3, J. Holbourn, Stewarton. 4, A. Robertson. *hc*, H. Picklea, Earby. *Silver-spangled*—1, J. Stewart, Barreead. 2, H. Colligan, M.D., Paisley. 3, R. Mackie. 4, A. Glen, Paisley. *Hens.*—1, R. Bruce, Bushby. 2, A. Stirling, Barrhead. 3, J. H. M'Nab. 4, H. Pickles. *Gold-pencilled.*—1 and Special, H. Picklea, Earby. 2, W. Creelman, Kilmarnock. 3, W. Peden. 4, J. Smith, Stewarton. *hc*, D. Watson, West Glen. *Silver-pencilled.*—1, H. Colligan, M.D. 2, H. Pickles. 3, Miss Lindsay. 4, J. Sharp, Johnstone. *Hens.*—1, R. M'Nab, Cardonald. 2, Miss M. Ingram, Paisley. 3, H. Colligan, M.D. 4, J. Jack, West Kilbride.

TOPPED POLANDS.—1, J. Forsyth, Carmile. 2, W. Hardie. 3, H. Pickles. 4, J. Hunter, Greenock.

GAME.—*Black-breasted and other Reds.*—1, J. M'Nab. 2, J. M'Laughlan, Paisley. 3 and *hc*, J. Waddell, Airdrie. 4, C. Jamieson, Forfar. *c*, J. Fraser, Dalmellington; W. Martin, Barrhead. *Any other Colour.*—1, D. Harley. 2, T. Davidson, Longtown. 3, R. Andrew, Barrhead. 4, J. Gray. *hc* and *c*, P. M'Farlane, Pollockshaw. *c*, J. Gray.

ANY OTHER VARIETY —1, J. Allan, Kilbirnie. 2, B. M. Knox, Kilbirnie. 3, J. Fulton, Beith. 4, A. Williamson, Grangemouth.

DUCKS.—*Aylesbury* —1, W. Mulligan, Springfield, Belfast. 2, Z. H. Heys. 3, A. Robertson. 4, R. Campbell. *Rouen.*—1, W. Mulligan. 2 and 3, J. Pollock, Mearns. 4, A. Robertson.

BANTAMS.—*Game.*—1, Z. H. Heys. 2, Bellingham & Gill, Burnley. 3, J. Mitchell, Perth. 4, T. R. Hamilton, Ayr. *c*, J. Gray. *Black.*—1, A. Mitchell, Paisley. 2, S. & R. Ashton, Mottram. 3, J. Waddell. 4 J. Wilson, Beith. *Any other Variety.*—1, S. & R. Ashton. 2, J. D. S. Crawford, Kilbarchan. 3, J. Waddell. 4, A. Grant, Kilbarchan. *hc*, A. Yendell, Galston; H. Yardley, Birmingham. *c*, T. Craig, Paisley.

SELLING CLASS.—1, Mrs. Alston. 2, H. Paton (Cochin-China). 3, C. Wilson (Hamburghs). 4, J. Gow, Kilbarchan. *c*, D. Skeoch, Stewarton; H. Fleming, Belfast (Hamburghs).

HOME OR FOREIGN BIRDS.—1, W. Spiers, Overton, Johnstone. 2, A. Liggatt, Paisley. *hc*, A. Eaglesim, Paisley.

JUDGES.—*Poultry:* Mr. J. Stewart, Helensburgh; Mr. J. M'Lachlan, Paisley; Mr. W. Farquhar, Barrhead; Mr. J. Lindsay, Stewarton; Mr. J. M'Innes, Paisley; and Mr. R. Calderwood, Kilmarnock. *Pigeons:* Mr. J. Muir, Milport. *Cage Birds:* Mr. J. Mair, Kilmarnock; Mr. A. Mitchell, Paisley; Mr. G. Grant, Glasgow; Mr. J. Kelly, Johnstone; Mr. J. White, Paisley; and Mr. R. Paterson, Howwood.

RABBITS AT THE YORK SHOW.

No doubt many of your readers, especially those in the Rabbit fancy, will remember the letters in "our Journal" on the above subject. Of one writer, who signed himself "J. B.," the greatest objection to showing at York was the fancy varieties having to be shown in pairs, he being afraid of his does being in young after such a show. But upon a letter appearing signed "M. Millington, *York*," stating the fancy varieties were to be shown in separate pens, I (who am "J. B.") was induced to send five pairs. They arrived home perfectly safe, but to my extreme surprise and indignation I found my finest Himalayan doe had kindled on Friday the 6th inst. upon the bare straw without any nest whatever. I may mention she is very young, and this is her first litter. Will Mr. Millington, as the manager of the Rabbit department at York, be kind enough to explain how this has happened if the Rabbits were put in separate pens? They were sent in separate compartments in the boxes. I should be glad to hear if any of the

other exhibitors of the fancy kinds have experienced the same.—James Boyle, jun., *Blackburn.*

THIRSK CANARY AND FOREIGN BIRD SHOW.

Thirsk does everything properly; so it advertised, and its Show was a great success. It was unfortunate that there were, I think, no less than four shows fixed for the last week in the old year. It was a mistake; but, once committed to the responsibilities of a show, it is difficult to withdraw. Three out of the four I knew something of, and wrote to the secretaries, advising them of the possibility of a collision, and suggesting means to make each subservient to the other, and the whole a success. Darlington, the first in the week, collapsed, which I am sorry for, as under careful management it should have pulled through. Of Stokesley, the last show of the week, I do not know the result, not having seen any return, but I trust the exertions of its committee were not in vain. There are, however, wheels within wheels, and motive powers in the machinery of a show, which do not always appear on the surface, and with reference to this, committees will find that independent action will tell best in the long run; and any town which can hold its show only by consent of its neighbour, bases its claims to public support on a sandy foundation, and should carefully study the fable of "the old man and his ass."

I found Thirsk in the same place, and the yellow 'bus with the pair of greys seemed as though it had been waiting in the snow since last Christmas to carry us (for my wife and the black bag went to see the Show) to the door of the "Black Lion," where the worthy host and hostess gave us a right hearty Christmas welcome, doing all that genial hospitality could do to remind us that Christmas comes only once a-year.

As soon as I was thawed I went to the Show-room, to wish Mr. Bailey the compliments of the season, and we sat chatting "Canary lore" over the fire till the small hours of the morning, when I left him trying to find out the softest board in the floor for a bed, as no persuasion could induce him to desert his post as night watchman over the fires. The result of his careful attention was apparent when I entered the room to judge. Among three hundred entries there was not a bird to be found suffering from the inclement weather, and it is only giving Mr. Bailey his due to say that a more careful, conscientious custodian of birds it has never been my pleasure to meet.

Of the Canaries I shall only say that they included the best specimens of the year. The Mules formed an excellent collection, Mr. Ashton taking the principal honours in Jonque and Mealy Goldfinch; and Mr. Stansfield running first in the "Any other Variety" with his splendid Bullfinch and Goldfinch. The *rara avis* of this class was Mr. Ashton's Bullfinch and Linnet Mule. As a hybrid it is unique, but is not just now in good show condition. Mr. Robinson's Brown Linnet Mule in the same class I noticed in my notes on Darlington. It has improved greatly.

A most prominent feature in the Show was the splendid exhibition of Foreign Birds, of which there was a large entry; Mr. W. Bailey, of Purfleet, Essex, making a great show, and carrying off the greater part of the prizes. Both the Secretary and his brother are great admirers of the more gorgeous birds of warmer climes, and Mr. W. Bailey's name will be familiar to all visitors to the Crystal Palace Annual Show, where he has always been a successful exhibitor. I think that at no distant date the readers of our Journal may expect to see a series of articles from his pen on the different varieties of foreign birds, with hints on their management. Such papers will be read with interest, and will lead to an extension of our prize schedules in this direction. —W. A. Blakston.

P.S.—I have said nothing about somebody subsiding gracefully into the snow. I promised I would not, and I have kept my word.

Belgian.—*Yellow, Clear or Ticked.*—1, J. M. Harrison, Belper. 2, Stevens and Burton, Middlesbrough. 3, Withheld. *Buff, Clear or Ticked.*—1 and 2, J. Close, Derby. 3, J. M. Harrison.

Norwich.—*Jonque.*—1 and 2, Moore & Wynne, Northampton. 3, R. Hawman, Middlesbrough. *hc*, W. Bailey, Essex. *Buff.*—1 and 2, Moore & Wynne. 3, R. Hawman. *Evenly-marked Jonque.*—1, R. Best Collection of Foreign or British Birds.—1, W. Bailey. 2, T. Bailey.

Judge.—Mr. W. A. Blakston, Sanderland.

THE SCOTTISH COLUMBARIAN ASSOCIATION, EDINBURGH.

The Society.—Although the Society has been established but a few months its *debut* may at once be recorded as a success, continuing and in some respects even rivalling, the oft-repeated successes of the Glasgow fanciers. At the outset its prospectus recalls the advanced and still advancing estimation in which Pigeon culture is now held. The many artistic phases of this pursuit and the curious naturalistic phenomena it discloses have long been recognised in the middle-class world; but the charmed circle of fanciers is ever widening, and "right honourables" may now be found therein aspiring to columbarian distinction—a sign of the times again attested in the acceptance by the Earls of Haddington and Rosslyn of the Honorary Presidency of the new Society In association with these gentlemen follow Messrs. Huie and Ure as President and Vice-President; two of our most ardent fanciers, and who, by great personal exertion, have forwarded the new undertaking, assisted by Mr. Robert Blair as Treasurer, and specially aided by the unremitting and good-humoured labours of Mr. Joseph Luis, the Society's Honorary Secretary. The members—principally residents of Edinburgh—must not be left out of account, for to them is due the merit of enabling the Association to appear in public furnished with superior plant, and with a sufficiency of entries to secure the treasury from embarrassment.

The Show, announced as the first annual exhibition of the Association, was held in the Music Hall, George Street, a room of commanding proportions, elaborately decorated, thoroughly lighted, in every sense commodious, and above all well-affected by the Edinburgh public. The choice of head-quarters so suitable harmonises with the refinement which should always influence our exhibition arrangements. A liberal policy marked the classification; the provision for young birds being too lavish, however, as an arrangement for repetition, although perhaps well advised for the special occasion. 465 entries were brought out by the schedule, comprising in all some 620 birds; and the arrangement of these in double rows, the contrast of the varied plumage with the white drapery, the shapely form of the cages, the liveliness of their occupants, the moving groups of visitors, and the hall itself—all contributed to a most pleasing *ensemble*. Viewed from the orchestra or gallery, whence a comprehensive survey of the whole scene could be taken, the effect was particularly striking, especially eliciting the admiration of those who were making their first acquaintance with a Pigeon exhibition, and even the oldest fanciers confessed that such a combination had rarely before been presented to their notice.

Without Pouters a show in Scotland would scarcely be acknowledged, Pouters, therefore, as ever, occupied by far the larger half of the pens. The very recent criticism of this variety in all its divisions leaves but little of general advancement to chronicle. With but trifling modification the remarks of a twelvemonth ago apply now; and, indeed, within the compass of a single season but a step or two only can be gained. It will, therefore, be almost sufficient to report clear evidences of progress as displayed—first, by the presence of a more than average number of specimens conspicuous for structural refinement; and next, by the eagerness of most exhibitors to possess themselves of crosses from stocks of sound pedigree. In Blacks the Vice-President carried many honours, showing no less than one-third of the number exhibited. So pronounced an effort on the part of an experienced fancier, together with the general usefulness of the birds possessed by other competitors, should be the "foreshadow of coming events."

Proverbial philosophy completely breaks down before the continued plumage-debasement of the Reds. "When things come to the worst they are sure to stand still," appears to be for them the reading of the old adage. But whether or no they are at their worst, or standing still, or are mending, matters but little. To the fancier of taste and skill they present an opportunity in the art of colour-enrichment which assuredly will not be lost, the more so as a basis of structure and carriage sufficiently sound remains.

The Blue classes were distinguished not only by numerical strength, but also by excellence. Birds of mark and character appeared at every turn; and, for the encouragement of English breeders, it may be stated that the class for young Blue cocks was headed by the London-bred bird which the week before had won the Crystal Palace cup for the best cock bred in 1870.

As White Pouters display no special structural advantages over their coloured kindred, purity of plumage is their essential distinctive title to consideration. This essential is being disregarded, even at Edinburgh, where better things might have been expected. Although many shapely birds enriched the White division, it must be insisted upon that an Adonis-like form is no apology for dirt, but rather intensifies the disfigurement. The bird's demeanour even favours the bad impression, and, any way, he is the worse of a town life.

Of other salient points in the Pouter classes much in praise might be said did space permit, but it will be enough to add that a determined spirit of progress is manifest amongst the Scotch fanciers. It is felt that the combination of superior form with refined colour and marking presents an unlimited field for tasteful exertion, and it

desired more and more to stimulate highly selective matching. Another communication will deal with the remaining features of this exhibition.—W. Volckman.

[Want of space has obliged us to omit some paragraphs.—Eds.]

POULTRY CONDIMENTS OR TONICS.

Mr. Mills, an apothecary in France, recommends from experience the following as an unfailing tonic or stimulant for debilitated fowls, and especially for young Turkeys during the critical stage, when he says its effects are most marked and salutary. The prescription is copied from the French *Journal d'Agriculture Pratique*.—Take

Cassia bark in fine powder, three parts	Gentian, one part
Ginger, ten parts	Anise seed, one part
	Carbonate of iron, five parts.

Mix thoroughly by sifting. A teaspoonful of the powder should be mingled with the dough for twenty Turkeys, each morning and evening. It is of the greatest importance to begin the treatment a fortnight before the appearance of the red, and to continue it two or three weeks after.

Export of Fowls to America.—By a letter just received from Mr. Simpson, treasurer of the New York State Poultry Society, in answer to some inquiries I made a month since, I am informed that on and after January 1st all poultry and other breeding stock were to be admitted into the United States duty free. Previously there was a duty of 20 per cent. *ad valorem*, which was an immense tax on really valuable fowls, and, though it was often evaded by a fee to the officer, was a great hindrance to importing good stock. The relaxation is owing entirely to the exertions of the Society, and will be good news to fanciers on both sides of the water.—L. Wright.

Coal Tar for Bee House.—In answer to your correspondent, "A Northumberland Bee-keeper," I have a wooden bee house. I covered it with asphalted felt about eight years ago, and I have tarred it once since, but I have never found the tar in any way affect the bees; in fact, I had the best two virgin hives of honey that I ever had out of the tar-roofed house the same year. Mine is but a small house, and only tarred on the roof, and possibly the tar might affect the bees more if the house were large and tarred all over.—T. E., *North Wales*.

OUR LETTER BOX.

Books (*A Recent Subscriber*).—There is no book on Spanish fowls only. "The Poultry Book for the Many" gives all needful details, and can be had free by post from our office if you enclose 6½*d*. in postage stamps, with your address.

Supply of Eggs—Houdan Moulting (*R. W.*).—You are the one out of the thousand. In country villages eggs made 2*d*. each during Christmas week, and it has been difficult in London to get eggs fit for the breakfast table at less than 3*d*. each. Send us your notes. Your Hamburgh cock is not moulting in a healthy manner, and the hens with him have been eating his tail. He must be removed, or they will spoil him by continuing their cannibal propensities. It is rather an indication that your birds are too highly fed. We shall be very glad to have your poultry experience. We consider it among the most useful and interesting information we can convey.

Brahma Pullet's Crop (*A Duffer*).—It may be your pullet has a broken crop, and it therefore hangs loose in front. If it is so, shut her up, let her feed sparingly, and drink but little at two separate times every day. She must have no water by her. If she have she will continue drinking in hopes of relief from her discomfort, and the malady will get worse. If she be compelled to abstain from water the crop will likely contract. You must feel carefully whether there is anything that almost closes the passage from the crop to the gizzard. We have known such a thing, and once took out a carrot 3 inches in length.

Game Bantams (*S. G.*).—If there is no special clause to allow it, the undubbed bird will be disqualified if shown against dubbed ones. The operation may be performed any time except during a frost. We do not advise you to pull out the flight feathers of the cock. If detected it will lead to a painful disqualification, and such things may be practised but they are not allowed. You may exhibit the Duckwing pullet with a good prospect of success if you put her with a good cock. We know no work devoted to Game fowls.

Egg Supply (*A. M.*).—Yours is a deserved success. You hatched your chickens at the right time for laying. It is as natural for a Hamburgh pullet hatched in April to lay in December as for a man to cease growing at twenty-five. They have lived and laid in spite of the sawdust, and not because of it.

Feathered-legged Bantams (*An Admirer of the Bantam's Form*).—The Bantams you speak of were formerly called Booted Bantams. They are principally excluded from the shows because none are shown. They do not lack admirers.

Fowls in Confined Space (*J. D.*).—You may keep a cock and four, six, or eight hens in the space 20 feet by 9, and a fowl house. The number will depend on your management and supply. We hardly need tell you such a limited space does not provide the many things that are essential to a fowl's well-doing. Road grit, growing grass, fresh mould, bricklayers' rubbish, lettuce or other green food must all be supplied according to the number of fowls kept. The best birds will be Crève-Cœur, Spanish, or Brahma, for egg-producing.

Cock Purple-combed and Moping (*Young Beginner*).—Separate the cock from the hens till his comb is thoroughly healed. They will eat it as long as there is any wound or sore. Purge the cock thoroughly with castor oil, then give Baily's and camphor pills.

Umbrellas and Sticks at Poultry Shows.—"J. H." informs us that the Committee of the Barrow-in-Furness Show have adopted his suggestion, that all sticks and umbrellas are to be left at the door.

Houdans and Crève-Cœurs (*Reader*).—A full description with illustrations was published in Nos. 62 and 63 New Series of this Journal, and republished in a collective form in our "Poultry-keepers' Manual."

Antwerps at Manchester (*W. Justice*).—You have adopted the right course. We cannot insert any relative statement until both sides have been heard.

Ground Bones for Chickens (*A Constant Subscriber*).—The smaller the pieces the better. We prefer the powder, but the sample, the fragments the size of pins' heads, will do. Green bones are quite as useful for the purpose as dry bones.

Thirsk Show (*A. J. W.*).—Mistakes will occur, and you will see in our report that Mr. Bailey did not shrink from his labours.

East Kent Poultry Show.—Mr. G. Raynor informs us that the third prize for Game chickens was awarded to him, and not to Mr. T. G. Ledger.

Sick Dragoon (*A Weekly Reader*).—Your bird has roup; we gave the most probable cures for this complaint in our number for November 17th, to which we refer you.

Points in Black Carrier (*T. A. Dean*).—Skull long, straight, narrow between the eyes, and flat at the top. Beak long, straight, thick; length of skull and beak 2¾ inches. Eye red; wattle of the eye round and regular—*i.e.*, of equal width. Beak-wattle tilting forward and standing well up. The plumage should be dense and close, so that the bird may have a solid look. The carriage should combine grace and strength. Shoulders broad, chest full, limbs long, head well up, so that the eye is directly over the toes, neck long and thin, back rather hollow.

Ligurian Bees (*H. Jenner*).—You may obtain a Ligurian queen either direct from Mr. Woodbury, or from those who advertise them in our columns, but you are not likely to get one until May or possibly June The price varies with the season. The best mode of uniting queens is fully described in our number published on the 5th August, 1869. You will find a smouldering roll of linen rags of not less than an inch in diameter, and lighted at one end, the smoke of which may be directed by the breath as required, the most efficient means of controlling and subduing your vicious bees.

COVENT GARDEN MARKET.—January 11.

We have no alteration worth quoting this week, and our supplies are sufficient for the meagre attendance of buyers we have now.

From observations taken near London during forty-three years, the average day temperature of the week is 42.9°, and its night temperature 31.3°. The greatest heat was 68°, on the 19th, 1828; and the lowest cold 4½° below zero, on the 19th, 1838. The greatest fall of rain was 0.90 inch.

WINTER-FLOWERING BEGONIAS.

FLOWERS are at all seasons valuable—never more so than at midwinter, and of plants blooming at that time Begonias are in my opinion amongst the most useful, whether as plants in the stove or as furnishing cut flowers for vases, epergnes, &c., for dinner-tables, for the elevated parts of which it is desirable to have suspended or drooping over the margin flowers which have a similar disposition on the plant. Fuchsias, than which nothing can be more beautiful in summer, are of this description, and so are the brilliant scarlet Begonia fuchsioides and the bright pink B. erecta multiflora in winter.

Begonias are of very easy culture, no roasting heat nor vapour-bath atmosphere is needed for their successful treatment. A kind of house which is neither a stove nor a greenhouse, in other words an intermediate house, suits them. From March to September they will thrive in a vinery as well as anywhere; the moisture and increasing temperature, with the free air-giving, induce a free but sturdy growth, and the subsequent dryness needed for the ripening of the Grapes also secures the ripening of the wood of the Begonias, and gives a wholesome check to the plants; for, when placed in the stove, they are again excited into growth by the moisture, and their tendency is to flower at once. I must now enter more into details, and shall commence with February.

In February the plants which are more than a year old will be out of flower, or nearly so, though some are truly perpetual-flowering; very unlike Perpetual Roses, which oftener bloom once than twice, to say nothing of being half the year dreary-looking objects. The old plants of Begonias will in February be past their best, and we shall keep them rather dry, but not so as to cause them to go quite off. From the base of the previous year's growth will come some strong shoots, which should be kept growing; therefore give a little water, but not much, from the time the plants begin to cease flowering, and early in March they will be at their worst. Never mind this, but turn them out of the pots, and, removing all the old soil that can be done without destroying every particle of root, pot them in a size of pot—clean both inside and outside—that will hold them comfortably. Good drainage must be given them, and to keep it efficient cover it lightly with moss, or better, with the rough parts of the compost. The compost may consist of the turf of a common where the soil is half loam half peat, and full of sand—a kind of soil in which Foxgloves and nearly all Ferns flourish, more so than in so-called peat, which is very often nothing but a soapy bog soil. If this cannot be had, then one part light turfy loam, the more turfy the better, chopped up small, one part sandy peat, and one part old dry cow dung, or failing that, leaf soil, with a sixth part, or half as much as the others, of silver sand, and the like of charcoal in pieces from the size of peas to that of walnuts; or boiled half-inch bones form a good substitute. Mix all together, and the whole will be a nice open compost, and with this pot the plants rather firmly, but not very tightly. Place them in the vinery if you have one started in February, and the sprinklings of water and the moist atmosphere will be most agreeable. Water carefully and sparingly until the plants begin to grow freely, and their doing so will be an indication of their having taken to the fresh soil. The moisture needed for the Vines will be all they require, and as to water none will be wanted as long as the soil remains moist, but when it is becoming dry give a supply of water sufficient to show itself at the drainage. At the same time the plants must not be allowed to suffer from want of water. It is the watering regularly, and when the soil is moist enough for every requirement, that renders plants so sickly in the hands of amateurs as a rule, and of gardeners also at times.

By June the pots will be full of roots, and the plants growing freely. Shift them into pots a size larger, and use the same compost as before, with good drainage. Do not give a large shift, for the one-shift system is not suited to Begonias, nor, indeed, to more than 1 per cent. of all the plants in cultivation. If the plants do well they will have made good growth by the end of July, and will then need a drier atmosphere, but being in a vinery they will have that on account of the ripening of the Grapes; yet if they are growing (and B. fuchsioides may be so, while B. Dregei may be flowering), remove them if you can to a later vinery. Shift again into larger pots at the end of July or the beginning of August, and they will continue growing up to September. Then, or at whatever time the plants have made a good growth, and seem to have ceased growing, give them plenty of room, which they ought to have at all times, and supply no more water than enough to keep the foliage fresh. Subject them to a month of this ripening process, and then remove them to a stove where there is a temperature of 50° to 55° at night, and 60° to 65° by day—they will bloom from September to February.

The only pruning the plants require is to cut out any worn-out shoots, but none that remain healthy. When, however, they become weak, and there are plenty of fresh and vigorous shoots from the base, remove them close to the surface of the soil. No training is needed, except it be putting in a neat stake the height of the plant, and tying the main shoots loosely to it, but it is only the straggling growths that need this. Stopping and other pruning Begonias will not endure, as by it we remove the blooming parts, and cause fresh shoots to push up from the root.

Failing a vinery, or if it be inconvenient to grow the plants there, they may remain in the stove through the summer, but from May to the middle of September they would do much better in a greenhouse than in a hot moist stove. Slight shade from bright sun in the hottest season of the year is necessary, whilst from August to April they cannot have too much light.

Besides old or large plants I grow a number of smaller ones. Early in June I take cuttings of the strongest parts, such as are rather firm, or not very gross, and 3 or 4 inches long. Cutting transversely below a joint, and removing the leaves halfway up, I insert the cuttings singly in 3-inch

pots. I fill the pots with soil, make a hole in the centre, then drop in a little silver sand, and, introducing the cutting, place silver sand round it or fill the hole level. I next water gently, and place the cuttings in a hotbed, shading from bright sun until they are rooted, which they will be by July. Care must be taken not to overwater, or the cuttings will damp off, and yet it is necessary to keep them moist. When rooted remove them to a vinery or other house where they will have slight shade from powerful sun, and a moist atmosphere, in which they will grow freely if properly watered.

When the pots become full of roots shift the plants into 4½-inch pots, which may be needed by the beginning of August or earlier, and at the end of September remove them to the stove or intermediate house. It is well to keep the plants rather dry and in a position fully exposed to the light up to the middle of December, when they will be showing flower, and I then shift them into 6-inch pots, put a neat stick to such as require it, and water carefully for a time—I mean sparingly, just keeping the soil moist, for if much water is given at this stage they fall back, and the flowers, and very often the leaves, drop; if this do not take place they flower about the middle of January, and go on to April, or longer. Being then rested until June by withholding water, and again started into growth, they make highly ornamental plants by October, and may either be allowed to bloom or be rested for a time in order to succeed the old plants. The latter and the cuttings will afford a good handful of flowers—some drooping, others erect, but all graceful, and of the brightest scarlet or pink—if not every day, very often from September to April, also for house-decoration plants that stand the dry atmosphere well, and if they are destroyed, as is not unfrequently the case with room plants, they are easily replaced. I would advise everyone to grow this class of plants in quantity. They are with me every-day plants, one or other being in bloom all the year round.

The kinds I grow for winter-flowering are—

B. fuchsioides.—Flowers scarlet, of graceful habit. The flowers hang down and are of the most lovely waxy coral red. The plant attains a height of 6 feet, and is feathered to the pot. It is the very best of all, being very ornamental in habit as well as flowers.

B. erecta multiflora.—Flowers pink, erect habit, but as graceful as B. fuchsioides, and it grows quite as tall. It is very free-flowering, the flowers drooping, and some say fragrant.

B. Ingrami.—Flowers deep rose, in large clusters, slightly drooping. Not so tall as the two preceding, erect habit and stiff.

B. prestoniensis superba.—Flowers orange scarlet. Plant very free-flowering; habit dwarf and compact. It is also a good summer-flowering kind. For winter it should not be started until June, as it is semi-herbaceous, no doubt owing to its parent, B. cinnabarina, though somewhat shrubby, owing probably to the blood of B. nitida.

B. insignis.—Flowers pink. Very free-flowering and good.

B. hybrida floribunda.—Flowers rose. Habit of B. fuchsioides, very elegant, and very free-blooming.

B. Dregei.—Flowers white. Plant of erect dense habit, very free-blooming and continues long in flower. In begins flowering in July or August, and produces a succession of blossom until spring. The flowers are very pretty, though not so conspicuous as those of many sorts. It forms a dense bush from 2 to 4 or 5 feet high. It will succeed in a greenhouse or vinery, and is then semi-herbaceous.

B. nitida.—Flowers blush, in large clusters. It is of straggling growth, and does well on a trellis, and trained to a stake in a pot.

The above are all good, and though I have grown many others I consider them the best. Of course, I shall be glad to receive information respecting any others that your correspondents may grow. I also would not be without B. manicata, flowers pink. It produces such clusters of delicate wax-like spray as to be quite charming. It succeeds very well in a vinery, flowering with the return of spring, and with me in a stove in February. Also that very thick leathery-leaved sort, B. hydrocotylifolia, which has bright pink flowers borne neatly above the foliage. A pretty plant for rooms, and for rockwork too hot and dry for Ferns. It flowers in January or February. —G. Abbey.

FLOWER GARDEN ARRANGEMENTS.

Never was there a time when so much attention was devoted to the cultivation of taste and skill in the arrangement of colours. The modern style of flower gardening has, so to speak, forced this upon the gardening portion of the community. The bygone-system of mixed beds and borders made no great demand upon one's skill in this respect, but since the fashion of massing large breadths of strong colours has prevailed, more attention has perforce been given to the effect which the various colours have upon each other. Occasionally flower gardens may be seen in which the arrangement of the colours is so good as to leave nothing to be wished for, but this is the exception rather than the rule. Glare and glitter are still in force, and that too in many public gardens, the arrangements of which are studied and followed in hundreds of private places, because it is supposed that the flowers in notable public gardens are certain to be arranged by persons possessing great artistic skill and refined taste; but, unfortunately, this is very far from being generally the case. In most instances no exception can be taken to the colouring in regard to its being correct, yet there is such a constant succession of primary colours that a gorgeous dazzling effect approaching vulgarity is the result. It is the want of refinement of which I complain—that quiet grace which tones down and affects an entire design in such a manner as to impart an indiscribable charm to it.

Scarlet, yellow, and blue are the dominant colours, and wonderfully striking effects may be wrought out with them; but it is to the various shades of pink, crimson, purple, and grey that the true artist turns for materials, which, when skilfully interwoven with those other bright colours, impart the highest possible finish to any design, be it large or small. How very rarely it is that justice is done to the beautiful colours of the fine-foliaged Pelargoniums; even our old favourite Mrs. Pollock is oftener seen with the flower trusses left on than not, and thus the work of the cross-breeder, whose aim was evidently to produce beautiful foliage, is altogether forgotten or ignored. The Golden Tricolors and many of the white-variegated Pelargoniums form most effective masses or ribbon lines with their foliage alone, serving admirably to divide other kinds whose chief beauty is in their flowers; so that those persons who disregard this most valuable property, and suffer all kinds and classes to flower indiscriminately, can hardly be aware of what they lose by overlooking the rich and varied beauty of the leaf tints, the introduction of which can in nowise affect the utility of those kinds grown for the beauty of their flowers.

To illustrate my meaning I will take a very common and very beautiful ribbon border of four rows—the first of Cerastium, pearly grey; the second of Lobelia Trentham Blue, deep blue; the third of Pelargonium Crystal Palace Gem, rich yellow; and the fourth Coleus Verschaffelti, deep rich crimson. Here are three out of the four kinds of plants used imparting the colour required by their foliage alone; therefore if Crystal Palace Gem is suffered to bloom, its flowers would quite spoil the effect. Or, supposing we want an arrangement which shall be so quiet in tone as to neutralise, or rather subdue, the effect of bold masses of colour on each side of it, we will take that beautiful silver-variegated Pelargonium Miss Kingsbury for our centre, surrounding it with a broad band of Purple King Verbena, and with an equally broad band or border of Manglesii Pelargonium; the flowers being kept picked off both Manglesii and Miss Kingsbury, such a bed in such a position is most telling. Then, again, how charming is the effect of a compact mass of the silver-variegated foliage of Perfection when seen in all its purity next such a deep pink kind as Maid of Kent! but if, when so placed, Perfection is suffered to produce its bold scarlet flowers, an air of vulgarity prevails, and the chaste and refined beauty of its foliage is altogether lost.

Our object, then, in arranging the colours in a group of beds should be to produce an effect of purity and brightness, devoid of gaudiness on the one hand or insipidity on the other; for it should not be forgotten that it is an easy matter to use too much of such plants as Centaurea, or even of Cerastium, as well as of those possessing brighter colours.—Edward Luckhurst, *Old Lands, Buxted, Sussex.*

FITZROYA PATAGONICA.

Seeing that Mr. Record has failed after four years' trial, both in light and heavy soils, in procuring anything like a specimen of this Conifer, I will state a few particulars as to the tree now growing here. It has attained the height of 9 feet 6 inches, and is 4 feet 4 inches through. These dimensions show that the style of growth is entirely different from that of Mr. Record's plant. Where the tree is growing the soil is light and rubbly. No special care was taken in planting the tree, further than taking off the turf and making the hole large enough to contain the roots, which were spread out carefully, so that they might be equally extended on all sides; then the soil was filled in and trodden down carefully and firmly, so that the wind would have little chance of loosening it at the neck, an occurrence which is most injurious to any tree.

The tree has been planted several years. In 1869 it grew 9 inches in height, last year it made 10 inches, and 10 inches of young wood, pendulous; but the pendulous growth of the previous year has risen quite erect, and so has every growth that has been made of the year previous. The leaders, of which there are several, and the side branches, keep pace in their growth. I think it a valuable addition to the pinetum, and have not the slightest doubt that it will rise to the height of 70 or 80 feet.—James Smith, *Fynone, South Wales.*

RECENTLY-INTRODUCED GRAPES.

Having grown and fruited most of the new Grapes which have been introduced within the last three or four years, it may be useful to some of your readers if I state my experience with them. There can be no doubt that differences of climate, soil, and treatment, have a great influence on the Vine as well as on other fruits, so that the results of my treatment here may be different from that of others, and different from what I should have arrived at under other circumstances. The merits and demerits of new fruits are much commented upon in the horticultural press, and sometimes they are subjected to undeserved abuse. It is scarcely possible for a gardener to write with confidence about a new Grape the first year of its fruiting with him, although in certain cases a pretty correct estimate may be formed; but it is best to have two or three years' experience before speaking confidently. There is more difficulty in introducing new fruits to the public than there is in the case of new flowers, and it is well for gardeners that it is so. Take, for instance, a new Grape; if a vinery is to be planted, and the Grape in question is said to be better than any of the older varieties in the same class, the gardener is anxious to give it a trial, and it is very annoying, after considerable attention has been bestowed on the plant, and valuable space appropriated to it, to find that it is much inferior to older sorts that would not have cost a fourth of the money. There is not a tithe of the disappointment felt over a new flower if it is not found worthy; a flower can in most cases be proved a few months after purchase, and if it is not quite up to the high character received with it, there is little harm done, and it is not worth while to get out of temper about it; but when you have been wasting your time over, and devoting space to a Vine or fruit tree which after two or three years produces fruit neither fit to place upon your employer's table nor to give to your friends, truly there is some excuse if you are tempted to use a few hasty expressions. Of course, it equally behoves those to be cautious who have the assurance to laud a new variety of fruit to the skies before they have seen it growing and had sufficient opportunity to test its merits. Most of the recently-introduced Grapes, if they do not quite sustain the high character given with them, are worthy of cultivation for some peculiarity of flavour or constitution.

Mrs. Pince's Muscat is a good-keeping sort, superior to Lady Downe's in flavour, but not in appearance. The berries set quite as freely as with Lady Downe's, both growing in the same house. The bunches are long, tapering, but the berries do not colour well. It is grafted on Lady Downe's, and the difference in colour is easily perceived. It has done best here on its own roots.

Muscat Champion is the best flavoured of all the new Grapes; none of the other so-called Black Muscats have the flavour so fully developed as this. It is a shy bearer, requires heat, and colours badly. It does best grafted on the Black Hamburgh.

Royal Ascot has proved to be an excellent sort, and has improved in appearance and quality; as a black Grape, both for early and late houses, it is well worthy of cultivation. The bunches are large, sometimes shouldered; berries large, black, and covered with a dense bloom; the flesh is firm and richly-flavoured. I have it grafted on the Black Hamburgh, but the White Frontignan is the best stock for it. I was much surprised last season at the effect of this stock on the Black Hamburgh. A grower in this neighbourhood, who sends his fruit to Covent Garden, had some White Frontignans planted in the same house with the Black Hamburghs; as the fruit could not be disposed of to the best advantage, the Frontignans were grafted with Hamburghs, and the Grapes from the grafted Vines were superior in every respect, the berries being larger and more highly finished; the plants had also the same peculiarity as the stock—viz., that of being the first to be attacked by red spider.

Of white Grapes the recent introductions are not numerous. *Golden Champion* is a very distinct sort, both as regards flavour and appearance; it has succeeded best grafted on the Black Hamburgh. The berries are large, with a peculiar and rich flavour. I think it tender, and not likely to put up with the treatment to which the Black Hamburgh is often subjected; it has, however, been exhibited in such magnificent style that those who have not been successful should try again. I fruited it for the first time last year.

Madresfield Court Black I have not grown, but having seen and tasted it in the hands of others, it seems to be a very desirable variety. The flesh is not so firm as that of Mrs. Pince, and it is said not to keep well after Christmas. The bunches are large, and the berries large and quite black. It is again very highly recommended by Dr. Hogg in the "Gardeners' Year Book" for 1871.—J. Douglas.

TEA ROSE CULTURE.

The answer to your correspondent at page 438 had determined me to continue the subject of my special favourite, the Tea Rose, but the many calls on the clergy at this season of the year prevented me from doing so before, and now Mr. Kent has forestalled me in some of my remarks.

I am but a beginner, so offer you my notes in all humility, and I shall be most grateful to anyone who will set me right if I err.

I have about sixty varieties of Tea and Noisette Roses, and if I were asked to name my favourites they would be as follows:—Maréchal Niel, Céline Forestier, Souvenir d'un Ami, Rubens, Madame Falcot, Madame Margottin, Comte de Paris, Archimède, Niphetos, Madame Willermoz, Madame Bravy, Marquise de Foucault, Monsieur Piton, Madame Charles, Souvenir d'Elise, President, Sombreuil, and last, though not least, Gloire de Dijon. These have done all I could wish; they stood the past winter in the open ground, and bloomed profusely all the summer.

I describe my treatment below. La Boule d'Or will not do here without the protection of glass, it will never open; the same is my experience of Marie Sisley; under glass both are fine. Now, I would ask your readers to tell me about Monplaisir; I have been much disappointed with it. On hearing its character I bought four as fine plants as one could wish to see; I treated them to some of the best places I could find—against a sheltered wall, in an open border, and planted out against a conservatory wall. I did not obtain during the season one flower worth looking at. It was shy to bloom, and when a bloom came it was as ragged, ill-shaped a production as you could well find. Archimède is a great favourite of mine; it is always in bloom, and if thinned out, so as to leave one bud on a shoot, expands like a beautiful white Camellia.

I find that the strong growers of this class do best on a very short Briar. Maréchal Niel I have against a wall, under glass, and as a standard; it is never bad anywhere, and with the tying up, described below, is as good in the open as under glass, perhaps even better, as I find the blooms larger. I am very favourably inclined towards Unique; it is a good grower, and its peculiar flower is very pleasing. Many of the newer Roses, including Belle Lyonnaise and Madame Levet, which, for the information of Mr. Kent, is one of the new seedlings from Gloire de Dijon, I have not yet bloomed, though I have plants of them.

In my judgment many make the mistake of planting Tea Roses in situations where they get the full heat of the sun all day, which causes the flowers to expand so rapidly that they lose both shape and colour. My Tea border is under a wall facing due east, but protected from the north. The soil, being stiff clay, was deeply trenched, some of the subsoil burnt, and a good supply of manure and old leaves worked in. The plants are in rows, with occasional trenches between, which trenches in summer are filled with good, rich stable manure, well trodden by pigs, and from time to time water is pumped in by means of a hose. I am constantly among them with the aphis brush dipped in a concoction of 1 lb. quassia steeped in two gallons of boiling water, and half a pound of soft soap. I pinch out all superfluous buds. When I want Roses of extra size I tie a piece of tracing or tissue paper, dipped in oil and then dried, round the stem of the bud, leaving the paper to project about 1½ inch beyond it; this draws out the bud, and causes it to elongate and to swell gradually. The paper must be increased in size according to the growth of the bud. The oil throws off the wet, which would otherwise cause the paper to adhere to the bloom; it also causes ants to keep their distance. I had many a fine bud destroyed by these pests last

season; they eat their way into the very heart of the expanding bloom. Madame Falcot when treated in this way was as fine as Maréchal Niel.

All my Roses are now snug beneath a covering of about 3 inches of cocoa-nut refuse and long stable manure; they are so near the river that I dread frosts; last year I lost but three out of four hundred. Next year I mean to be daring enough to try my luck on the exhibition table.—Stiff Soil.

BEDDING CALCEOLARIAS IN 1870.

I do not think that the cause of Calceolarias dying-off so extensively as they have done for the last few years has ever been discovered, although numerous opinions have been expressed upon the subject, nearly every gardener having a different one. Some of the theories advanced appear reasonable, and those who had the energy and opportunity have set themselves to prove their truth, and I believe with good results. Although the past summer has been an exceptionally dry one, quite unfavourable to the Calceolaria, especially with so much sunny weather, I think in many places this favourite bedding plant has never grown better; and in many other places, as far as I have seen, there has been less loss from disease, as it is called, than formerly. This, I conclude, is because the grower pays more attention to the cultivation of the plant, especially from the time of propagation till it is placed in the flower garden, and even in the latter department gardeners find it advantageous, when it can be done, to make special provision for their Calceolarias.

Some of the growers of the Calceolaria who were most successful during the past summer, tell me that they propagate as late as the middle of November, if the weather will allow, and make their cuttings as short as possible, most of them without a heel to them, the object being to delay the rooting until the New Year. They use a finely-sifted heavy rather than light soil, and when the cuttings are well rooted the centre shoot of each is nipped out; this checks their rapid growth into bulky plants until the days lengthen, and they can have more light and air to encourage a healthy growth. The young plants are kept as cool as possible both night and day, and in a short time every shoot each plant makes is again pinched.

While the plants are breaking into growth again, a suitable place is being prepared for them either in cold pits or frames, or in trenches in the open ground; if the latter, the trenches are made 4 feet wide, and a good spit of earth thrown out on each side makes them about 18 inches deep. The bottom is covered with any rough siftings of soil, and the remainder is made up of similar soil to that in which the plants are to be grown in the flower garden. I might remark that if protection can be found the trenches are to be preferred on account of the want of every foot of space under glass at that time of the year, and the trenches afford the plants a similar position to that which they are to occupy in the flower garden.

The transference of the plants from the cutting-frame to the trenches is effected in the most careful manner. With a view to facilitate this the cuttings at propagating time are placed as far apart as circumstances will allow, in order that the plants may be taken out without root-breakage, and the same care is taken when planting in the trenches. There is another advantage in using trenches—namely, a convenient space can be allowed to the plants. At all times they are exposed to the sun and air when the weather is not frosty. I am told that to plant out early is a great point in their favour, for if left until ordinary bedding stock goes out, which, perhaps, is as late as June, the Calceolaria is to a great extent exhausted, and the roots become so entangled, and the process of moving at that time so difficult and dangerous, that the plants scarcely recover until the summer is nearly gone. I think this is a reasonable excuse for early planting; and again, we all know that if the plants are too large the shock of moving causes the wood to ripen-off, and then there is a great chance of the first flowering carrying them off entirely, and those which do not die fail to produce blooming wood until too late.

In the flower garden the wants of the Calceolaria must not be neglected, and as the plants like a cool moist bottom, it has been found beneficial to place a moisture-retaining soil under them at about 1 foot deep, and quite 6 inches thick. If the soil above is light, make it heavier by suitable additions. A rather close soil I have always found to be more suitable, provided it is not too poor, but it should be made good to a considerable depth, as Calceolarias, like most bedding plants, root very deeply into the ground. I think trenching should be carried on as systematically in the flower garden as it is in the kitchen garden, because it would afford the plants a beneficial change of soil. Where the soil has been worked for a number of years for the same purpose, it would be better to take it out to a good depth and add fresh soil made up with a large proportion of good peaty loam. This experiment has answered perfectly well during the past summer with the Calceolaria; therefore it is to be recommended for other bedding plants, excepting those which would be liable to grow too coarse at the expense of bloom.

Watering and mulching during a long period of hot and dry weather are such essential points in the culture of the Calceolaria, that they ought to claim special attention, for then it is, and when there is an absence of dewy nights, that this plant appears to suffer most. The difficulty lies in keeping the plants growing and the wood from ripening-off under the burning sun, so as to insure a continuous blooming time; but during the past summer much of this difficulty has been overcome by attending to the above details. Although in what I have stated there is nothing new or more than what an anxious cultivator would think of, I am not afraid that this plan will be less successful with those who practise it than the rough-and-ready treatment which very many growers pursue with this the most useful, and one of the oldest and most popular bedding plants we have. After a dry summer, or if the month of September should be showery, it is surprising how suddenly the Calceolaria commences a healthy and luxuriant growth, which would, if the season could be prolonged, produce one of the most brilliant masses of bloom ever witnessed, and such as no artificial treatment could, perhaps, ensure. Still I think this disposition of the plant is a good guide to the cultivator as to the wants of the Calceolaria, and should be imitated as much as possible, for of all the hardier sorts of bedding plants it requires the most careful treatment.—T. Record.

RABBITS AND TREES.

Having from time to time seen communications on this subject in The Journal of Horticulture, especially from persons anxious to get up patches of evergreens in game coverts, I send you a few remarks, the result of several years' experience in planting.

If it is practicable entirely to exclude rabbits and hares from the parts planted, I would advise that the wire netting used be not less than 3 feet wide, and not of larger mesh than 1½ inch. It should be fixed to upright stakes, and be well pegged down. Three inches at the bottom should be turned outwards, and laid flat on the ground, which should be levelled, and made up over the bottom of the wire along the whole length. The rabbits, hurting their claws without result in the buried horizontal portion of the wire, soon give up scratching at it; but some one should occasionally go round and make up the ground to the wire where required.

I wish, however, to speak more particularly of planting single trees or shrubs in bare parts of coverts or plantations. It is provoking to have these devoured year after year, and I think it better to plant fifty with efficient protection, than five hundred to be barked and mutilated, to take their chance of surviving in a deformed and stunted condition. It is known that trees when first planted are especially liable to be attacked by rabbits. We observe loppings of trees in coverts entirely cleared of bark, whilst branches and twigs of the same size growing within reach are untouched. In the same way recently-planted trees are sure to be selected amongst others of the same kind and size. I have found the recommended preparations of night soil, gas tar, train oil, quicklime, &c., both bad for the tree and inefficient, unless renewed every month. I have used cradles made of common wire netting 2 feet wide, 2-inch mesh. This I cut or rather break across into lengths of about 2 feet. These I place round the young trees with the rough ends of the wire at the bottom and the top, and bring the level sides together, fastening them with soft wire previously cut into lengths of 3 or 4 inches. About 2 inches at the bottom and top of the cradle should be turned outwards, which gives additional protection. Each cradle should be pegged down with two pegs. The diameter of these cradles will be about 8 inches, the height about 18 inches, and the cost about 3*d*. This may seem a large cost to protect a tree worth only a penny, but much vexation is saved, and they require no renewal. The labour of fixing is inconsiderable. I can fix from twenty to thirty in an hour with ease. Such trees as Larch and Spruce, if 3 feet high, which I find the best size for planting from my

own nursery, into which I introduce them at 1 foot, will, of course, have their lower branches compressed by such cradles; but I do not find that this interferes with their growth. The same may be said of Hollies, and other evergreens. If larger cradles are desired, the netting may be obtained of any width, and the width must be three times the diameter required for the cradle. Rabbits are more likely to jump inside the larger cradles, which should, therefore, be higher. Much additional protection is obtained by putting pieces of Gorse or Thorns inside the cradle, and reaching over the top of it. I tried this year tying Gorse twigs with the bushy end resting on the ground about 2 feet up the tree. This appeared to answer until the late snow, when the rabbits ate first the Gorse, and then the tree. Thorns cut up into short pieces are a much better protection. A few handfuls of these placed round the tree to a width of a foot and a height of 18 inches, seem as good as the wire cradles, and cost less.

I warn your readers not to be misled by lists of trees and shrubs which it is said that rabbits will not eat. I have tried nearly all, and the only evergreens I find untouched are Yew, Box, and Rhododendron. My plantations are mostly narrow, bounded by grass or arable fields, and I keep no more rabbits than I am obliged to do in justice to the foxes, that these important animals may earn an honest livelihood, and not be driven to rob the farmyards.

Larch is the worst of all trees to get up amongst rabbits. They bark it even in summer, and eat it quite down. Spruce, Silver Fir, and Scotch Fir, are all eaten down in severe weather, especially when rabbits can reach to the top of them, though their bark seems less attractive. Do not, however, confuse the work of rabbits or hares with that of squirrels, which bite off the leaders of young Spruce, apparently to exercise their teeth, as they leave the tops on the ground. Squirrels must be killed if Spruce are to be reared. Oak, Spanish Chestnut, and nearly all forest trees are liable when first planted to be barked by rabbits, and should be protected as directed above. Of Holly, Privet, and common Laurel, rabbits and hares eat both bark and leaves. Broom hares bite quite down, even when of large size, and eat the young twigs. Berberis Aquifolium and Portugal Laurel are amongst the last shrubs touched, but in the present severe weather the rabbits are attacking young plants of both, biting the leaves off the former, though they do not seem to eat them, and barking the latter, though to no great extent. I have not spoken of choicer Conifers, but I find that Abies Douglasii, Cupressus Lawsoniana, Wellingtonia, and probably most of the others suffer more or less.

I may conclude by saying, that where cover for game is the chief object, nothing answers so well as the common Bramble or Blackberry, and the varieties of Briar or Dog Rose, including Sweetbriar. These take readily to any soil, require no nursing, grow very fast, and as shelter are far preferred by pheasants to the smooth-leaved Berberis, and to Rhododendrons.—C. W. D.

ANONYMOUS CRITICISM.

I HAVE read the article, "New Year's Hopes," by "WILTSHIRE RECTOR," in No. 510 of THE JOURNAL OF HORTICULTURE for this year, an article beaming with truth and kindliness. But I fear the medal has its reverse, and we should not, I think, refuse to look on the other side if by so doing we can effect further good.

After reading that article I was led to reflect on horticultural literature in general, and on the anonymous part of it in particular. For my present purpose I will divide our writers on horticulture into two classes. First, those who sign their names and addresses to their writings, and secondly, those who write anonymously. It is to the latter anonymous writers that I would now specially address myself.

I do not condemn anonymous writing altogether. What we call "leaders" may very properly be published anonymously, because in that case there is a clear and acknowledged editorial responsibility. Many good things have also been written anonymously, which, probably, never would have been written if the writer had been compelled to complete them by attaching his or her signature. But I think if a writer says anything that is derogatory to the productions of another, he is bound in honour to attach his name to his opinion. I will state a case which I think those who regularly peruse our horticultural periodicals will admit not to be an imaginary one.

A cultivator, after years of thought and labour, succeeds in raising something different from what has gone before. It is exhibited, and obtains a mark of honour, and he sees, or fancies he sees, a pecuniary as well as an honorary reward looming in the distance, when lo! some anonymous critic starts up, and by faint praise or subtle insinuations produces a state of scepticism in the public mind, which causes his novelty to fall flat in the market. The motives for this line of action are doubtless various. I need hardly pause to speak of those who from prejudice reject a good new thing, because they are punished severely enough by finding their neighbours' gardens or tables rejoicing in the possession of gems or viands which their warped judgment has rejected. The anonymous critic may be some brainless man, who cannot distinguish between a good thing and a bad one. He may be brainless, and envious in addition; himself incapable of producing anything superior, he endeavours from sheer envy to lessen the value of what others more skilful or persevering than himself produce. Or he may be a rival in trade—one of the sharks of society, who knows full well that if he can only induce the public to wait until he has purchased and raised a large stock of the novelty, he will reap a larger share of the profits.

I was told by a nurseryman of respectability and position not many months ago that the loudest declaimer against a new plant of his—a plant of rare merit—was the largest purchaser of it! And after this declaimer had purchased and raised a large stock of it, knowing that its merits must in time become known and cause a large demand, coolly changed his opinion, recommended it, and pocketed considerable profits. Now this was an injustice to the public, because everyone is anxious to possess a good thing as soon as possible; and it is a still greater injustice to the raiser or introducer, for it deprives him of the fair reward of his knowledge, skill, and labour. It is worse than the infringement of a patent—it is cowardly as well as dishonest, because here the patentee, so to speak, has no redress at law.

I think I have said enough to show that this is a blemish in our horticultural literature which calls loudly for a remedy. I admit that many indifferent, nay, worthless, things are continually palmed on the public by dint of puffing; but even here, as the puffer usually attaches his name, it would be more manly to question their merit by an open than by an anonymous attack

Let me then, in conclusion, deferentially and kindly, but earnestly, entreat my brother writers in horticulture not to abstain from expressing any adverse opinion they may hold on any new thing, but to place their names manfully in support of their opinions, that the public may know what weight to attach to them, and that those opinions may be fairly and honestly canvassed.—WILLIAM PAUL, *Waltham Cross, N.*

CHRYSANTHEMUM CULTURE.

I ASSURE Mr. Castle that I have no wish to disparage his mode of growing the Chrysanthemum, my object in writing being to elicit a few practical truths. I do not believe a Chrysanthemum grown from a cutting will in one season ever produce too much wood to form a specimen, and it is a well-known fact that some varieties will not produce enough under the most favourable circumstances. A point in favour of the use of liquid manure is the production of good foliage, which I consider contributes much to the beauty of the plant; and if vigorous wood and foliage be grown, large flowers will be the result. I cannot conceive why the plants should require additional nourishment after the flower buds are formed, as I think there must be a greater demand on the resources of the plant during the formation of the buds than in the development of the flowers; but I am not surprised that Mr. Castle's plants require additional stimulus by that time, for I am convinced that plants not plunged will require watering once, and in hot weather twice a-day, and I am of opinion that such frequent waterings with clear water for several successive months must greatly impoverish the soil. I must confess to never having seen a Chrysanthemum die through being overwatered; and were such a case to come under my observation I should at once assume the cause to be insufficient drainage, and not the too frequent use of the watering pot.

In plunging I make a practice of placing a piece of brick or an inverted flower pot under each plant for the purpose of drainage, and to prevent the roots from protruding through the bottoms of the pots. I still maintain that it is absolutely necessary to plunge pots in the open air to protect the roots from the vicissitudes of heat and cold. As regards the extra skill required in watering, I should hope there are very few men employed in gardens who have not intellect enough to

know whether a Chrysanthemum requires water or not. In a former paper Mr. Castle recommends August as the time for giving the plants their final shift, but he now recommends the first or second week in July for Pompons and early-flowering kinds, which is more in accordance with my own views.

As Mr. Castle hopes his writings will be received in good faith, I beg to assure him that they will be received in such by me; but as he differs from so many practical gardeners on various subjects, I think readers should be cautious not to arrive too hastily at conclusions.—H. Benham, *Upper Holloway.*

GLAZED WALL.

Just as I was about to accept an offer made me of twenty ground vineries at a certain price, a week or two back I observed your recommendation, for Vine-growing, of glass being put against a wall in the shape of a lean-to house, which article suggested to me that we should build a house 120 feet long and 12 wide against a certain wall covered with nice young Peach trees, &c., allowing them to remain there, and growing Vines as well up the 14-feet roof. We also wished to make this the home of bedding stuff during the winter. What size of saddle boiler should I require to heat such a place, supposing that 40 feet were heated by a chimney laid down as a flue, and the rest of the length by 4-inch hot-water pipes? Could we not have the house all in one, or would it be a disadvantage? Which is the best white Grape for a cold vinery?—Subscriber.

[We approve of your covering your Peach wall with a lean-to glass roof. The modes of doing so we have frequently alluded to. To do justice to the Peaches, the Vines up the rafters or roof should be fully 6 feet apart. These spurred will allow a very fair amount of light to reach the back wall. Royal Muscadine and Buckland Sweetwater will answer well in such a house, and so will Calabrian Raisin as a late Grape; but as you intend the house for wintering large quantities of bedding plants, it would be as well not to encourage late Grapes, but such kinds as you would cut by the middle or end of October. In such a length of house we would prefer a division of glass in the centre. We approve of taking a flue along one end of the house from the boiler, and that flue will keep out frost for the 40 feet proposed. Two 4-inch pipes to the other end from the boiler would also keep out frost. If more were wanted, more piping would be necessary. Were we heating such a house we should be inclined to make the one end from 50 to 60 feet long, put the furnace and boiler at that point, take the flue to one end and pipes there too, and pipes to the other end; thus you could have the one end of a 120-feet house much earlier than the other. We would use a saddle boiler 24 inches long, 22 wide, and 20 inches high, or about that size, which would enable you to have more piping if desirable.]

RED LEAD PROTECTING BULBS FROM MICE.

In answer to the inquiry of the "Rev. C. P. H." in vol. xix. page 477, respecting keeping mice from bulbs, I am enabled to state that I dust all my bulbs with red lead, and that not one of them has been touched by mice. Last year I did not dust the bulbs, and the result was that they were nearly all carried away by rats or eaten by mice.

I dust all my seed Peas and Beans in the same way, and not one of them is touched; but if by chance I sow one line without red lead they are usually nearly all devoured by mice.

I may add that I do not find the red lead injure the Pea crop nor the bulbs. I have known the mice bore after the Peas and Beans, and, finding them red-leaded, leave them untouched. —G. W.

MAKING BORDERS FOR WALL TREES ON BAD SUBSOILS.

On an entire renovation of the garden being made here, and when starting to take out the foundation for the wall, we had to go to the depth of 6 feet before a solid foundation could be got. After 20 inches of soil on the top, all the rest was loose red sand. I decided to concrete both sides of the wall to the width of 14 feet. When the wall was finished, the little good soil on the top was removed to the garden quarters, the sand wheeled right away to the depth of 30 inches at the wall below the ground-level, and 33 inches at the out edge, so that there is plenty of fall for water to run off; and along the front a drain was cut, 8 inches deep, and the width of a spade. Being all ready for the concrete, there was brought nice-sized gravel, laid in quantities of about four tons, and one ton of coal-ashes, to which was added one ton of lime fresh from the kiln, which had as much water thrown on it as make it fall; then it and the gravel were mixed together, covering all over with the ashes. After letting it lie in this state for twelve hours, it was well mixed by turning it over several times, adding more water if required, but keeping it rather adhesive than otherwise (as it sets quicker when not too free), and laying it on at once to the depth of 3 inches all over, beginning at one end, so that there is no treading on the concrete until perfectly dry. When smoothing it down, if found too firm and not smoothing well, have a watering-pot with a rose, and sprinkle a little water over it, but no more than will enable the operator to level it properly, bearing in mind to let it have the same fall from the wall to the outside as the foundation of sand on which it is laid. It must now be let alone until it is thoroughly hard, which will be in about ten days if the weather is fine and dry, when some nice round boulders were put all on the top, to the depth of 4 inches, and filling up the drain in front at the same time to the same level. Then a good thick sod, with the grass side downwards, was laid all over the drainage, before the regular filling-up with soil was commenced, which, when done, was raised 6 inches higher than the natural ground, to allow for subsiding, keeping it always a few inches higher at the wall—giving a gentle fall to the Box-edge. From the nature of our subsoil here, I have found these borders, through the very dry season which we have had, to contain more moisture than other parts of the garden which are not concreted.

Not wishing to spoil the wall by nailing, which has several objections, studs with eyes were put in between every third line of bricks, standing about an inch from the wall, having stronger ones at the ends to act as stretchers; and after the wire, which was galvanised, was passed through all but the end ones, and drawn tight; a 9-inch in length piece of small rod-iron, with an eye at one end to fasten the wire to, and nearly all the length, had a screw-thread worked on, when the wire had been fastened to the other end, put through the end stud; then a screw-nut was put on, so that all was made as tight as required. The first outlay may be a little more than the yearly bills for nails and shreds, but a very few years would soon cover the first expense, as a few mats go a long way in tying.

Trees trained to the wire here, in a general way, do not bloom so soon in spring as when close to the wall, and the fruit is cleaner and more regular in colour; and as for insects, there is no harbour at all for them.

From the success attending the above operations, I am induced to send them, knowing that where such a subsoil exists, if followed, the results will be as successful as here.—A. H., *Thoresby Park Gardens.*—(*The Gardener.*)

[The Editor of "The Gardener" remarks, "The young wall trees at Thoresby are models of health and fruitfulness"—just, we may add, as every department of that great garden is an example of Mr. Henderson's good management.—Eds.]

ROYAL HORTICULTURAL SOCIETY.

January 18th.

This was the first meeting of the year, and though the day offered a favourable contrast to those we have lately had, still everyone was surprised at the number of plants exhibited, and the unwonted gaiety which the Council Room presented, so early in the season.

Fruit Committee.—G. F. Wilson, Esq., F.R.S., in the chair. Messrs. Veitch & Sons, of Chelsea, sent excellent specimens of Snow's Winter White Broccoli, which was highly commended by the Committee. Mr. Tillery, of the gardens, Welbeck, sent a brace of Cucumbers, the variety raised by Mr. Hollah, of Rufford Abbey. Mr. Tillery stated that he had been cutting from two to three brace every week for the last eight weeks, and he considered it the best winter Cucumber. Signor Domenico Piccorillo, 41, Wigmore Street, sent a quantity of Naples Giant Chestnuts and Sweet Oranges. The Chestnuts were very large and fine, and a special certificate was awarded to the exhibitor. Mr. Osman, gardener to R. Holland, Esq., Stanmore Hall, Middlesex, sent a dish of nice St. Michael's Oranges, but they were not ripe. Col. Le Couteur, of Bellevue, Jersey, sent a dish of Bahia Navel Orange, the pips being produced in a nipple on the end of the fruit. The flavour was good, though rather acid. Alfred Smee, Esq., F.R.S., exhibited specimens of Lemon from Sicily, severely attacked with a scale which has attacked the Lemons all through Sicily with the exception of Palermo. Wherever this attacks the fruit it never ripens. This scale is allied to that which attacks the Oleander. Mr. Meredith, of Garston, near Liverpool, sent splendid bunches of Muscat of Alexandria Grapes, which received a special certificate. Mr. Tillery, of Welbeck, sent a bunch of Gros Guillaume and Trebbiano Grapes which had been cut for a month and kept in a bottle of water.

Messrs. Carter & Co., of Holborn, sent a dish of their Main Crop Potato, some of which were boiled to test the flavour, which the Committee did not consider of any special merit. Col. Le Couteur sent a collection of Pears from Jersey, consisting of Colmar d'Aremberg, Jaminette, and Pengethley, none of which were ripe. Mr. W. Ewart, the gardens, Apthorpe, near Wansford, sent a dish of very fine Easter Beurré Pears, which received a special certificate. Mr. Clark, the gardens, Rochampton Lodge, sent a good dish of Glou Morçeau Pear, which received a special certificate. Mr. Jennings, of Shipston-on-Stour, sent specimens of Fairy Apple, which was much admired for its ornamental character. Mr. Miles, the gardens, Wycombe Abbey, sent a dish of the Black Crab, or Pomme Noire. Messrs. Backhouse & Son, of York, exhibited a dish of Galloway Pippin, a handsome Apple, which was ordered to be cooked and then submitted to a sub-committee to report to the next meeting. Mr. Scott, Merriott Nurseries, Crewkerne, sent 250 varieties of Apples grown on the Paradise stock. These were sent to show "how well Apples keep when wrapped up in old newspapers. Mine were mostly sound. They keep until May, hardly any of them going off." The collection was in good condition, and received a special certificate.

Prizes were offered in Class 3 for the best three dishes of Kitchen Apples. The first prize was awarded to Mr. Turner, for remarkably large and fine fruit of Golden Noble, Alfriston, and Blenheim Pippin. The second prize went to Mr. Parsons, gardener to R. Attenborough, Esq., Acton Green, for Golden Noble, Blenheim Pippin, and Dumelow's Seedling, large and well ripened, though not equal in size to those from Mr. Turner. Good dishes of Blenheim Pippin, Bedfordshire Foundling, Gloria Mundi, Alfriston, and Golden Noble were also shown by other exhibitors. Class 4 was for Kitchen Pears. The best three dishes came from Mr. Turner, and consisted of Catillac, Uvedale's St. Germain, and Vicar of Winkfield. Mr. Gardiner, Lower Eatington Park, was second.

Floral Committee.—Mr. Fraser in the chair. From Mr. Denning, gardener to Lord Londesborough, Grimston Park, Tadcaster, came a splendid collection of Orchids, among which were magnificent specimens of Lælia anceps, Lælia autumnalis, Saccolabium giganteum, and Lycaste Skinneri; also Calanthes, Dendrobiums, Odontoglossums, and Oncidiums, and a beautiful specimen of Barkeria Skinneri superba, and a fine deeper-coloured variety of Lælia autumnalis. A special certificate was given for the collection, and special certificates for the fine specimen of Lælia anceps and Barkeria Skinneri.

Messrs. Backhouse & Son, of York, sent a fine example of Lælia autumnalis, a large-flowered variety, which received a special certificate.

Messrs. Veitch, of Chelsea, sent a fine collection of Orchids and other plants, for which a special certificate was given. In this were a large plant of Lælia anceps, a fine Mormodes Colossus which had a second-class certificate, Bolbophyllum auricomum bearing much resemblance to a Grass in flower, several Odontoglossums, Lælia anceps Dawsoni, a beautiful variety; Cypripedium vexillarium, a finely-coloured hybrid between C. Fairrieanum and barbatum, which received a first-class certificate; Phajus irroratus, a hybrid between P. grandiflorus and Calanthe vestita alba; several Palms; and an unnamed species of Stenorhynchus from Chiriqui, with waxy purplish-rose flower heads.

Mr. Burnett, gardener to W. Terry, Esq., Peterborough House, Fulham, sent a good example of Anæctochilus Lowii, Angræcum sesquipedale with five flowers; Cypripedium longifolium, delicately coloured, and very pretty; and Saccolabium Harrisonii and giganteum.

Mr. Green, gardener to W. Wilson Saunders, Esq., Hillfield, Reigate, sent a small group consisting of Sonchus platylepis, a handsome large-leaved Sow Thistle from Teneriffe; cut specimens of Æonium Holochrysum from the Canaries, forming very pretty golden pyramids, and Maxillaria leontoglossis, very pale yellow, spotted with purple.

Mr. Williams, of Holloway, exhibited a pretty group of Palms, Dracænas, Genetyllis Hookeri in excellent bloom, his hybrid Solanums loaded with fine high-coloured fruit, and several fine-foliaged plants. A special certificate was given. Messrs. Lucking Brothers sent forced flowers, such as Hyacinths, Azaleas, and Tulips, in ornamental baskets and china pot-holders, likewise several remarkably tasteful bouquets. For these exhibitions a special certificate was awarded. From the Society's garden, Kensington, came a collection of Orchids, including fine specimens of Cattleyas, Lycaste Skinneri, &c. For this a special certificate was given.

Mr. Ware, Hale Farm Nurseries, Tottenham, had a special certificate for an interesting collection of Succulent plants. Mr. Turner, Slough, sent Tricolor Pelargoniums Mrs. Headly and Mr. Rutter, which is to be seen again; also Chinese Primulas blush, lilac, and red. A special certificate was awarded Mr. Turner for these, also one for a fine collection of seedling Aucubas in berry, some with green others with mottled leaves, varying in the depth of their colour, and some of them bearing a remarkable profusion of berries. Mr. Stevens, of Ealing, sent a collection of well-bloomed Chinese Primulas and one of Cyclamens, for which a special certificate was given. From Mr. Williams came an Aucuba with large yellow berries, which, however, do not show to such advantage as the red berries; also Aralia platanifolia, which is likely to prove a handsome plant for subtropical gardens.

Mr. Wiggins, gardener to W. Beck, Esq., Isleworth, sent a fine collection of Cyclamens, a white, called album fimbriatum, being nicely fringed; Mr. Goddard, gardener to H. Little, Esq., Twickenham, several finely-coloured varieties, Snowflake, a fine white, and one called fragrans, delicately scented. A beautiful spike of Odontoglossum Blantii came from Messrs. J. Brooke & Co., Fairfield Nurseries, Manchester. This was awarded a special certificate. Mr. George, gardener to Miss Nicholson, Putney Heath, sent a yellow-berried Solanum of the Capsicastrum section, but the fruit was only partially ripe. Messrs. Dobson & Son, Isleworth, had a special certificate for a collection of Chinese Primulas, of various colours, of a fine strain. E. J. Lowe, Esq., Highfield House, Notts, contributed a rather numerous collection of new forms of British Ferns; of these Adiantum capillus-Veneris admirable, and Scolopendrium vulgare consummatum, received first-class certificates. Messrs. Cutbush and Son sent Aucuba japonica fœm. aureo-maculata with a large yellow blotch in the centre of the leaves, a finely-marked variety; and from Messrs. Carter & Co., High Holborn, came a case of the fruit of Solanum ciliatum (Lamarck), of which it is stated the plant grows from 12 to 18 inches high, has shining dark green foliage, and is well adapted as a pot plant for table decoration. The fruit is highly ornamental, being upwards of an inch in diameter, and of a fine reddish-orange colour.

Messrs. A. Henderson & Co., Pine-Apple Place Nurseries, received a special certificate for a fine pot of Lily of Valley, exhibited along with a group of Palms, in which were several very ornamental species for table and room decoration. A special certificate was given for the group. Messrs. A. Henderson likewise had a second-class certificate for Ficus lanceolata, an elegant dark-leaved species.

Prizes were offered for the best nine Ivies in pots. The first prize was taken by Mr. Turner, of Slough, with Hedera Helix lucida, a fine shining-leaved kind; latifolia maculata, lobata major, aurea, algeriensis, heterophylla, grandiflora pallida, the small-leaved variety, and maculata. These plants were trained as cones. Messrs. Lane sent a collection trained as pyramids on wire, among which were Rægner's, Gold-blotched, Clanwoodiana, and canariensis, all of which are very pretty. Messrs. Cutbush also sent two collections, among which were several of the above and other fine varieties.

Mr. W. Robinson sent a number of horticultural tools and instruments which he had collected during his recent travels in America; also various dried fruits, as Peaches and Plums, fruits preserved fresh in cans, Asparagus similarly treated, Indian Corn fresh, and prepared as Pop Corn pepper, in which state it is said to be like arrowroot for puddings; as well as Apples, Onions, and Potatoes, many of them from the Salt Lake. Dried specimens of a pretty alpine plant, from the summit of the Rocky Mountains, attracted considerable attention.

General Meeting.—G. F. Wilson, Esq., F.R.S., in the chair. After the election of thirty-two new Fellows, and the announcement

of the Committee awards, the Rev. M. J. Berkeley directed attention to some of the most remarkable subjects exhibited. With regard to Ficus lanceolata, he considered it would be extremely valuable if it proved as hardy as Ficus elastica, so would be the yellow-herried Aucuba if its berries retained that colour when older. The beautiful branched spike of Odontoglossum Bluntii also deserved particular notice, more especially as he believed it was the first time a branched raceme of it had been shown. He considered he ought to mention that the Easter Beurré Pears from Aptborpe Gardens were the produce of grafts he had brought from Lille, inserted in a Potato, in 1838; that winter, some would remember, was excessively severe, and it was many weeks before the grafts could be worked, and yet they had grown, and the tree was now in the most flourishing condition. The peculiarity of the Navel Orange, from Bahia, producing seeds only at the apex, and not in the pulp as with other Oranges, was then referred to as having a parallel case in the Portemanteau Gourd. Of Ada aurantiaca it was stated that a Frenchman, lately looking out for subjects for ornamental pottery, was enraptured with it, considering it one of the most beautiful of all plants for the purpose. Mr. Berkeley said he would mention, as an ornamental species, the Sonchus shown by Mr. Wilson Saunders but principally because there were other plants from the Canaries to which he wished to call attention, particularly the many shrubby species of Echium, which it would be extremely desirable to re-introduce for greenhouse decoration.

Mr. Berkeley then drew attention to the fruit of Stangeria paradoxa, the first, he believed, that had ever been perfected in this country, though male cones had been. This singular plant was allied to the Cycads, but was so like a Fern that it had been at first described as a species of Lomaria. The "Botanical Magazine" of 1859 contained a good figure of the male plant (t. 5121), and it was there remarked, "This very remarkable plant, which in its habit and foliage resembles no other of the Natural Order to which it belongs, was first in 1835 imperfectly noticed by Kunze as a South African Fern (Lomaria), and was sent by Dr. Stanger from Natal to N. B. Ward, Esq., and by him given to the Chelsea Botanic Gardens long after—viz., in 1851. It was first described by Mr. Moore, from imperfect specimens, as a 'Zamia-like Fern,' or 'Fern-line Zamia,' and the opinion expressed that its affinity appears to be rather with Cycadeæ than Ferns, which has since proved to be quite correct. In 1854 specimens with cones were exhibited to the Linnæan Society by Mr. Stevens (Proc. Linn. Soc. v. 2. p. 340), and since then both male and female cones have been produced at Kew, but unfortunately not in the same year. Of these, a pair of female cones, formed in April, 1858, produced perfect ovules, and withered away; and in the same month of the present year another plant produced the male cone figured in our plate."

Frequent complaints, Mr. Berkeley said, had been made by persons who had sown Aucuba seeds that they could not get them to germinate; he believed that this was owing to want of patience, for the seeds lay in the ground several months before germinating. Dr. Thomson had found them come up very well at Kew when sufficient time was allowed. The same remark applied to the Scarlet-berried Elder (Sambucus racemosa), to the beauty of which when in fruit in Aberdeenshire he had at a former meeting called attention, and he had since procured a mass of seed for distribution among the Fellows of the Society. If seeds slow of germination were sown in autumn they would mostly germinate in spring, but if sowing were deferred till spring they would often not germinate till the following spring. He would therefore recommend all persons to have the pots in which seed was sown properly labelled, and not to throw the seed away rashly. Mr. Robinson's collection, already noticed, was next referred to as being of an interesting character, especially the preserved fruit; and in connection with the Pop Corn used in puddings, Mr. Berkeley said the small compact varieties were the best for the purpose. He then produced some heads sent by C. W. Strickland, Esq., grown fourteen miles north of York, their perfect state of ripeness being in his (Mr. Berkeley's) opinion a great triumph for so northern a latitude.

Mr. Marshall said all must have noticed the frequent complaints which had been made of the similarity of our exhibitions, the sameness of the exhibitors and the subjects, and he would submit a proposition which he thought would tend to effect an alteration in this state of things. It was, however, only a proposition, and no doubt would admit of considerable modification and improvement, and in what points he would be glad to learn. It was this—that those who might be desirous of competing should send in their names to the Secretary of the Royal Horticultural Society, accompanied with an entrance-fee of £5, and at the same time name the twenty stove or greenhouse plants which they would prefer to grow, and out of which they were to exhibit ten in May or June, 1873. These were to be bought on a given day, in 6-inch pots, of any nurserymen who might be agreed upon by vote among the subscribers; the plants to be marked by means of a piece of tape, tied and sealed round the stem or lower branches, for the purpose of recognition, and be inspected once a-year, or more frequently if considered necessary, by some one appointed by the Council. The Society to give a challenge cup, value £50, which if won three times by any one person was to be his property. The entry fees to be divided into first, second, and third prizes, according to their amount and number. This scheme Mr. Marshall thought would remove what had been so often complained of—that young exhibitors had no chance against those who had been longer in the field, inasmuch as all would start at one time and show at one time.

The Chairman remarked as no one had come forward to claim Mr. Bateman's prizes for cut Cattleyas, they would be offered again at the next Committee meeting, which would be held on February 15th; also that the Annual General Meeting would take place on February 14th.

At the meeting of Council this day, it was decided to recommend Messrs. J. Bateman, F.R.S., John Kelk, and E. J. Lowe, F.R.S., to the Fellows for election at the next annual meeting, in place of Messrs. Andrew Murray and Sigismund Rucker, and Dr. Thomas Thomson, F.R.S., who retire. Mr. John Clutton is recommended as Treasurer, and Lieut.-Col. Scott, R.E., as Secretary. Messrs. Wilson Saunders, John Clutton, and Sigismund Rucker are nominated for the Expense Committee.

PORTRAIT OF MR. RIVERS.

FORCING SEA-KALE, ASPARAGUS, AND RHUBARB.

A dish of compact bushy *Sea-kale* from 4 to 6 inches in length is very different from that from heads which average from 8 to 10 inches long. We have several times been nonplussed at seeing in some of our largest places small houses filled with Asparagus before Christmas and onwards, and hundreds and hundreds of heads of Sea-kale coming in at once in a warm dark place. We felt ourselves at a loss as to how this could be done. We have looked at the large gardens and the large space devoted to Asparagus and Sea-kale, but knowing something of the little space a large piece of such plants can be squeezed into in a forcing house or pit, the wonder with us was where the plants were to come from year after year. We knew a clever cook who would not be satisfied with strong white Sea-kale some 5 inches in length, but would merely nip out the central part, about 1½ inch in length, and who wanted, therefore, an immense quantity for a dish. Why, the whole of our little kitchen garden, if all Sea-kale, would hardly have kept up a good succession from November to May at that rate. In seeing these large beds under forcing treatment, seeing also a good stock of such vegetables in summer, the wonder to us was—knowing that *Asparagus* plants taken up and forced are of no use afterwards—where these forcing plants could come from; but we are not at all surprised at some such cases now when we find that all the earliest successions are, as respects the plants used, bought every season. Under such circumstances Asparagus and Sea-kale may be had every day in winter, even if the garden is not very large. Such a daily gathering would be impossible where only a small space can be devoted to such vegetables, and dependance must rest on home-raised plants in the open air. We have thought it right to mention this so prominently, because many who, seeing what others have, are dissatisfied with the amount of Asparagus they have in winter, would be still more dissatisfied if they were not well supplied with shoots from the open air in spring. The gentleman who purchases freely in this respect, and has but a small kitchen garden, must have a greater and more regular supply than a proprietor in similar circumstances who depends entirely on plants of home growth. All this, simple though it be, is often apt to be overlooked.

Unless the ground is very suitable, deep, rich, and rather light, it is not often that Asparagus is worth taking up to force until it is four or five years old from the seed, and then the plants are of no further use. This taking-up plan and giving the help of a hotbed or a pit is, perhaps, the best for the first or earliest crop in winter; but it is always expensive, owing to the loss of the plants. For successions, it would be more economical to grow plants in beds, that could be forced by hot water or dung linings, forcing these beds every alternate year. The most of us with limited room take up a piece every year, and at first are satisfied with occasional, instead of daily gatherings.

For the later spring Sea-kale some similar plan to that referred to as respects Asparagus in pits may be adopted, and thus the same plants may pretty well be forced every year. For early supply we think it in every way the most economical to take up a lot of roots at the end of October, and place them for successions in a warm dark place—say in a tempe-

rature of from 55° to 60°, with 10° more at the roots. There is not the same loss with them as with Asparagus taken up, as instead of being of no further use after forcing, every bit of the forced roots, when cut up into 4 or 6-inch lengths, hardened off, and planted out, soon makes a fine plant. Of late, partly owing to birds interfering with the seeds, we have raised few Sea-kale plants from seed. We prefer planting the pieces of the roots in rows in the way referred to, and find they make better plants than seedlings. Some of these pieces grew so strongly the first season, that we have taken them up in the following November; but in general we let them have two summers' growth before raising them. Thus, supposing we plant the root pieces in March or April, 1871, we should generally lift to force again in October or November, 1872.

Rhubarb taken up to force may be transplanted again in the same way; but it is as well that each piece should have a bud. There is no necessity for anything of the sort as respects the roots of Sea-kale; we have used them as small as a straw of wheat; but we like them better if as large in diameter as our little or even our middle finger. These cut at bottom and straight across at top, and of the lengths specified, are planted with the dibber firmly in rows 2 feet apart from row to row, the upper end being close to the surface of the ground. To keep vermin from them, a cone of ashes is laid along the row. As the spring advances the upper end will bristle round the edges with buds, and the only trouble required is to thin these out to two or three. With seedlings there will only be the one bud. From seed sown in April we have had fine plants for forcing in the second autumn, but we think there is less risk from fly, birds, &c, by using pieces of the roots.

Our reason for alluding to the matter is, that we know there are thousands of cases in which the holders of gardens are satisfied with Sea-kale in the spring months, by placing a pot over it, with or without protecting material, as leaves or litter. They look upon getting fresh plantations, rearing seedlings, as something to be shunned. Many of these might have a dish not every day, but frequently during the winter, were they convinced that the roots taken up could be cut to pieces and planted again. We have seen very fine Sea-kale in a common cellar without any covering, where it was dark enough; and when wanted early the roots were packed in large pots, watered with water at about 100°, and pots placed over them and kept close to retain the heat. We have seen it very fine in a close box near a kitchen fire. In fact, it will do very well in any place where a little heat can be obtained along with darkness.

In the open air after this time, where appearance is no object, Sea-kale may be forwarded after the frost is out of the ground, by placing over it a foot or even less of clean tree leaves. The shoots will make little mounds in the leaves before they are 6 inches in length, so as to show you they want looking at. On taxing our memory, perhaps the very sweetest and whitest Sea-kale we ever saw was gathered from beds out of doors, covered in the autumn with 7 inches of bog earth, and that covered with a foot of litter. We have had it very fine covered with clean ashes, but these do not fall off so clean as the bog earth. Under pots it can be had very clean, the great point is to cut in time before it becomes lanky, and then every bit, except a scale or two at the base, should go to table. Much ground would be required if only the heart bit were cooked.—R. F.

HOAR FROST.

When summer droughts are gone, and autumn rains have ceased to fill the running brooks and flood the river banks—when the short sunless days and long cold nights have stolen from the soil its generous warmth—then the keen, mastering, all-subduing Frost wakes up from his long summer sleep; by slow degrees he throws aside the torpor of inactivity, and musters all his powers for the coming struggle with winter storms. With a cruel smile he mocks at summer's beauty and autumn's lingering growth, and in his long duration threatens to rob spring buds of their promise. Down from snow mountains, and over icy plains, and across frozen streams he comes nearer and nearer; a clear bright sky, not blue but white, and a sharp ringing air through which sounds travel fast and far, herald his approach. Through the dark hours of the night he steals silently along, working best and surest when night is dying into morning. Nothing can stay his progress, everywhere he spreads his pure garment of dazzling beauty; over fields, and hedges, and woods, and broad highways leading to busy cities, and lonely footpaths leading out into Nature's desolate places, he throws his glittering array. Nothing too high or too low; he climbs the loftiest hills, and sinks into the lowliest valleys; he covers with an equal grace thatched cottage, and ancient church, and stately hall, and sloping lawn, and creeping moss, and withered Ferns, and tiny pebbles.

He passes through quiet lanes and breathes his destroying breath on every wayside weed, or wandering insect seeking too late its winter home; he crosses with rapid strides the wide open common, and uttering a cry of distress the birds seek the shelter of the nearest covert; he lingers in the forest where the tall naked trees stand forth in their magnificence of form and branch and interlacing twig, and turns each venerable Oak and sturdy Elm into coral reefs of glittering whiteness; he hangs graceful plumes on the lady Birch, yet leaves not the smallest blade of grass or fallen acorn unadorned. He creeps into every hole and cranny, looks over every garden wall, enters every open door and unclosed shutter. He paints his colourless pictures on every cathedral window, and writes in pencil lines of exceeding beauty the ancient story of his visit on every pane of glass. He silences the sweet music of the running brook, changes all its laughing smiles to still cold stone. He interrupts the current of the mighty river, driving to its deeper depths the lives that sported near its surface. He presses on closer and closer to the homes of men, hangs glittering icicles round cottage porch where Roses and Jasmine so lately bloomed, and stands waiting for admission at the well-guarded door of princely mansion. He lays a cold heavy hand on every living thing that comes unfriended within his reach; he overtakes the laggard gardener, and seals the death warrant of his tender treasures. He hushes all too soon the redbreast's song, and tracks the thrush to its safe retreat within the warm entwining arms of the thick Holly. All around the dwelling places of men he weaves his sparkling web, turning each drop of moisture to brilliant crystal, subduing all colour to his ghost-like whiteness. He finds his way to every town and village, passing noiselessly through the open squares where wealth and plenty are safely sheltered from winter frosts; through narrow streets and dark alleys, where the want of food and fuel makes his presence keenly felt. He pushes his way through the porous walls of mean-built houses, sits by the hearth an unbidden guest, steals from the fire its accustomed warmth, from the home its welcome comfort; he brings strength to the strong, and weakness to the weak, enfeebling the feeble step, and blanching the maiden's cheek, and imparting a deep joy to the young strong life that can bear his keenest blasts. Over all the hoar frost throws a charm, a marvellous grace, reveals to us a new creation, before which we stand in reverent wonder.—Maud.

SNOW and ICE DESTRUCTIVE TO GLASS ROOFS.

We may here make some remarks as respects lean-to orchard houses that are at all flat, in reference to their carrying a good weight of snow when glazed with large squares, say 20 inches across from bar to bar. These lean-to's are rather more than 11 feet wide, 10 feet high at the back, and from 4 to 4½ feet high in front, according to the ground. Such a roof would subtend an angle of from 55° to 60°, and, therefore, be considerably flatter than a roof at 45°, the angle subtended by a right-angled triangle. On a roof at 55° the snow will lie longer than on one at 45°, but until this season we never knew it lie long enough to do any harm. In our larger house we do not think a square of glass was cracked, for the snow, as it got heavy, slid off, or melted gradually away. Here, however, nothing was done to interfere with the cold and the snow except keeping the house shut. In the smaller house other matters were alike, except that for securing comfort and preserving some things that otherwise might have been injured, a little firing was used in an iron stove, which tended to melt the snow a little towards the top of the roof, and the moisture trickling down towards the front under the snow froze in the sharp frost, and became a firm mass of ice and snow, which we could not move if we wished. The greater weight of this mass told on the glass in some cases, so that in looking over we found we had to replace two squares broken outright by this congealed weight, and we find there are four or five more squares cracked in the middle, which we shall replace the first fine day. Now, the cracking of these few squares we attribute not at all to contraction or expansion, but merely to the weight of the frozen mass of ice and snow over them, and that weight would not have been felt but for the heat from the iron stove and the keen frost acting together, nor if, whilst the snow was soft, we had swept the snow from the lowest part of the roof, as

then that on the upper part would have slid right off. The truth is, that we wanted the snow to lie as a good protection, and even in this respect we shall be gainers by it, as the benefit derived will greatly exceed the value and trouble of replacing five or six squares of glass.

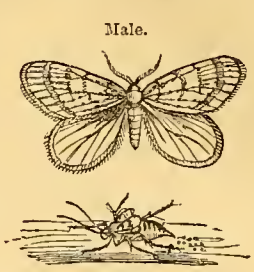
From such a simple matter a useful lesson may be learned. If there had been no artificial heat, if the lower snow had been moved, if the squares had been 4 or 5 inches less in width from bar to bar, or if the squares had been 21 or more ounces to the foot instead of about 15 ounces, then in either case it is likely that no square would have been broken.

We are quite aware that glass is often broken by ice forming and expanding in the lap betwixt the panes of glass. In steep-roofed houses, and even in sashes to pits that have a good incline, this is most apt to take place in frosty weather at the lowest squares, where the first square rests upon the wood, and that all the more in proportion to the heat used inside and the severity of the frost outside. When long squares are used, this often entails great loss from the chipping and cracking in front of these terminal squares. We have known cases in which, owing to very sudden and extreme changes of temperature, this cracking from the expansion of frozen water would take place here and there over a whole roof. Generally, however, it is the terminal front square of glass that suffers most from this cause. We say nothing now of puttied laps, and glass laid edge to edge without laps, and how far these would in the body of the house neutralise this ice-expansion. In our practice we have without glazed laps, but narrow laps made in the usual way, the glass lying as close as possible, square to square, suffered very little from the ice-expansion generally; but we have had a good many front squares cracked where the glass joined the wood. To counteract this, many years ago we had small squares of zinc, say, according to the space between the sashbars, of from 3 to 6 inches in depth, that terminated the glazing in front, the zinc instead of the glass resting on the front wood. The zinc was roughly grooved beneath to let condensed moisture out. In severe frost we have had these small zinc squares raised from the wood fully an inch in the centre by the expanding ice, but the squares of glass behind them were untouched. The zinc squares were easily brought to their level when the frost was gone. We have nothing of the sort in the orchard houses. As it is, we think we have escaped very well with so few squares cracked. It is where heat is used inside that the ice is so apt to accumulate at the bottom squares of the roof. With improved rafters and sashbars, to collect the condensed moisture, so that it shall neither fall over the house inside nor find its way out over the front plate of the sashes, there would no doubt be less of this accumulation of moisture and ice-expansion; but most of us are glad to get common conveniences, though we duly estimate all improvements.

There is another case in which these small terminal zinc squares are useful. Sashes for frames and pits are now often made with a narrower rail or plate in front than used to be the custom. These are often moved from the front as well as back. It matters not if you have ever such a nice handle for this purpose, if the front rail is at all narrow, the chances are if one hand holds the handle, the other seizes the front rail or plate, and smack goes a heavy thumb on the front glass, almost with the certainty of cracking it. The zinc terminal would save the cracking. "Ah! but how careless and slovenly." True, most true! but, unfortunately, the careless and the slovenly seem inbred and natural to most of us. You may paint all your garden and house doors very nicely, furnish them with all needful handles for opening and shutting, and you will be fortunate if in a fortnight you do not find your paint disfigured with dirty thumb and finger marks above and beneath the handles, where there is not the least occasion for them to be. Even nice finger-plates screwed on will not thoroughly save you from the annoysance, and yet the handle would have been sufficient for all that was wanted, without using the other hand to the style of the doorway at all.—R. F.

SOME PREDATORY INSECTS OF OUR GARDENS.—No. 2.

Some persons when hurrying along a country road or lane on a cold day in December or January, and endeavouring to persuade themselves that because they were walking quickly they were really getting a little warm, may have given a glance in passing at a paling or wall, and seen there sitting very composedly some male individuals of the Winter Moth (Cheimatobia brumata), shown in the accompanying figure. The dumpling-bodied females are, however, rarely seen in such positions, their business lying elsewhere. A momentary feeling of surprise may come across the observer, if he is at all interested in natural phenomena, that in the winter season insects should thus come forth; and if he think about it, he may propound the theory that the specimens are in a state of hybernation, and are waiting for the advent of spring. This is not so, however. The Winter Moth comes out from its state of torpor in the chrysalis state, and though it usually emerges during some mild break in the weather, it will live a certain time through frost and snow. A pleasant windfall many individuals prove to certain hungry spiders, who make prey of them in fault of better food. The appearance of this Moth seems suited to the season. It is not at all downy, but the wings present a bare aspect, which befits its wintry though brief life.



Cheimatobia brumata.

Now this brumata, harmless as it might be deemed when viewed only in its moth state, is a terrible destroyer of vegetation. The ravages of the species are to be noted most years, sometimes in the woodland scene, sometimes in the orchard, then again in the garden; for the caterpillar, though it has a great liking for Hawthorn, is in no wise particular, and will transfer itself very comfortably from one species to another as opportunity offers. But its *penchant* for Hawthorn is a decided annoyance to those gardeners, of both sexes, who pride themselves especially on their trim and verdant hedges. In other days I can remember more than once being warned off sternly by the owner of a garden plot, from whose hedge I had simply plucked a few leaves, without injuring a bough or even a twig; and in fact there have been cases where persons have been absurdly particular about their hedges enclosing their grounds, which said hedges were seen by their neighboure, and yet almost careless about the arrangement of the ground within and not open to inspection. Are not these persons comparable to certain others one meets with, who devote much time to the decoration of the exterior of the head, and trouble themselves very little about the right ordering of the brain which fills it?

To return to our Winter Moth, however. It is clear that a garden pest of this sort can only be effectually kept under by attacking it in its various stages at the different seasons of the year. Mr. Newman, whose labours in this direction—that is, in the investigation of the economy of predatory insects—have been so persevering, and as yet scarcely appreciated, points out minutely what may be done. The eggs of this moth, which are greenish white and of a tolerable size, are laid by the wingless females in crevices in the trunks of trees, sometimes also on the branches, and in nooks and corners. Every batch of eggs destroyed means not only the reduction of the caterpillars in the coming season, but cuts off also those of which, had they lived and thriven, they would have become the parents when they emerged as moths. Egg-hunting of this sort is tedious work, though one way of killing these eggs, Newman shows, is by deferring the pruning of fruit trees until after they are deposited, when the prunings will carry away a number of eggs with them. Of course it is understood then, that they must not be buried or scattered about. The moth is, perhaps, the most important object to attack, for it is as certain that dead moths lay no eggs as it is that dead men tell no tales. The German mode of proceeding is to daub a composition around the trunks or stems of trees likely to be ascended by the female moths. The best composition for the purpose, says Mr. Newman, is a mixture of Stockholm tar and cart-grease, a sticky-enough compound; and since the absence of wings necessitates the use of legs, and the moths, when they quit their chrysalis state in the earth, naturally move upwards, they may be taken in numbers by this expedient, the capture of the males being a matter of secondary importance.

The number of eggs deposited by each female varies from 150 to 200; and when thousands of these are thus entrapped and settled, the following spring is likely to show a great diminution in the number of caterpillars infesting the garden. Nor does any evil result then ensue to the trees or shrubs about which a circle of this composition is drawn, though it is admitted that "applied in the warm weather of April and May it has proved destructive in many cases, probably from its greater

fluidity at that time, allowing the tree to absorb it in drying." Also we note, "the composition tightens the bark, which should therefore be slit the next summer." Of the caterpillars while young the gardener generally takes little heed, and indeed it would be by no means easy to hunt them up when newly hatched, since they appear at the first expansion of the buds, which buds afford them their first supply of food. This is in the month of April, at which time the sparrows and other species of birds may be noticed to be busily engaged in an attack upon the buds, giving rise thereby to some controversy. It is asked, "Do they visit the buds for the sake of the caterpillars, or because they admire the flavour of the early vegetation?" Now, though birds are extensive destroyers of insect life, I conceive in this case that the buds are the primary object sought, the caterpillars being then very minute; still, as many are thus killed it lessens our indignation, and the birds' conduct may be deemed partly justified by the result. "There's no place like home," says the song, but if you have no home you cannot enter into the spirit of the utterance. Acting upon this, the caterpillar of the Winter Moth, as soon as it can, provides for itself a home amongst the leaves, and its food being all around, it can feed if it chooses without exposing itself much to view. Many must, in spite of this, be carried off by parent birds to their nestlings, and swarms are also killed while very young by the cold winds and spring rains. The colour of this caterpillar varies much from a pale green to a smoky black; it is one that even the entomological tyro at once recognises as belonging to the family or subdivision known as the Loopers (or Geometræ), though it usually rests, when getting of some size, in a one-sided posture, with the head curled round. I believe that a period of five or six weeks is generally sufficient to mature the caterpillar and prepare it to become a chrysalis. In some places children have been employed to pick off these caterpillars from bushes and the lower branches of trees. They may be beaten off in quantities also, as they readily drop from their retreats if this expedient can be ventured upon.

I referred in my previous paper to one conspicuous pest which annually visits our Currant and Gooseberry bushes. A little investigation will enable us, if we wish, to discover the eggs of the Phœnix Moth (Cidaria ribescaria) in those districts where it occurs, for it is not uncommon in various parts of the British islands, though I have not detected it in those places within the London district with which I am acquainted. These, which are deposited by the moth during the summer, are to be found in the bark of the bushes named, where they remain through the winter. The shape of these eggs is rather singular, resembling that of a powder-flask in miniature, and marked with ridges. The caterpillar rarely occurs in sufficient abundance to do any marked damage, differing therein from the too-well-known V-Moth (Halia wavaria), which, at the moment our bushes are getting a little reprieve from Abraxas grossulariata, begins to attack them unsparingly; and those who pick Gooseberries and pop them into their mouths without scrutinising them, are likely enough to eat a wavaria or two, as I have myself done. The V-Moth also deposits its eggs in the summer, and those who make a point of looking after the eggs of insects when there is little to be done in the garden, may succeed in detecting and extinguishing some of these. The caterpillars are unpleasant in appearance, warty, and very variable in colour, falling readily from their food with a slight shake, and remaining doubled up a long time. The chrysalis is placed amongst the leaves in a slight web. Though usually a July moth, in early seasons it may be seen in June—as, for instance, in the very warm summer of 1868, I noted some specimens were flying about at the middle of that month. This species is decidedly cockneyed, and succeeds in attaining its full dimensions in spite of London smoke—indeed some town specimens surpass in size others from a distance off.

One of the most curious particulars connected with entomological science is that regarding the long gaps which occur in the history of some species—how they are seen and then lost sight of for scores of years, to turn up again; or how some modern investigator verifies a fact which had been noted by a man who lived in the times of his great-grandfather. During the past year a new item of information turned up relative to a small beetle (a weevil), which Mr. Newman states was first written about in 1833, and subsequently the "Letters of Rusticus" contained some account of it; then, though often named as one of the enemies of the Turnip crop in field or garden, nothing of importance was recorded about it until Mr. Cordeaux observed its habits last winter. This little black weevil (known as Nedyus contractus), in spite of its size, is capable of inflicting considerable damage, and is only one, too, out of four or five insects which are partial to these vegetables. The author of the "Letters" had stated that "the eggs were laid on that part of the bulb which is above the ground, and the grub which comes from it eats into the rind of the Turnip, making it hump up into warts and all manner of rugosities." Mr. Cordeaux exhibits specimens "more or less covered by a mass of knobs and rugosities, in many cases completely altering the shape, and impairing both the quality and growth of the root. Each of these knobs or excrescences contains a small white grub, much sought after both by rooks and wood-pigeons, which come daily to feed upon them." It appears also that though all kinds of Turnips are attacked by this, the Swedish suffer least, being harder. How to best meet this enemy is a difficult question; the encouragement of the birds named, or of others which may play a similar part, would not do much good, for it is stated that their mining operations expose the roots to the influence of rain and frost; and, moreover, so determined are they to get all they can, that they pierce the bulbs in search of more when they have exhausted the knobs. As prevention is better than cure, some plan might be devised for the assailing of the imago, which, probably does its business in the early part of the autumn.—J. R. S. C.

NEW DOUBLE WHITE ZINNIA.

Why has not the double Zinnia been more grown than it is? During the hot summers of 1868 and 1870 it ought to have done especially well, and in the former year I saw it in the gardens of M. Souchet, at Fontainebleau, very fine indeed, while some fine stands were exhibited at the Metropolitan Floral Society's Show at the Crystal Palace last September; still they ought

to be more grown than they are, and when "well done" there are few flowers more effective. There have been attempts to prove that there are a dozen or more varieties of colour, but this is not so, some three or four—scarlet, orange, purple, and lilac, being clearly marked. I have now to announce a novelty in the way of a good double white. There is a dirty white in

commerce, but it is a *vaut rien*. This has been raised in America, and the stock has passed into the hands of the firm of Carter & Co., of High Holborn. The figure which is here given will afford some idea of the form and character of this fine novelty, although, of course, no idea can be given of its purity and elegance.—D., *Deal*.

National Tulip Society.—At a meeting of the subscribers of the Society held at Cambridge last year, after the annual show, it was resolved that the Exhibition for 1871 should be held in Manchester, and the Council of the Botanical Garden there have given £15 to the funds, will provide a tent for the Exhibition, also bottles and other things necessary, and will advertise the Exhibition along with their own. The Exhibition will be held on the 26th and 27th May, in conjunction with the National Horticultural Exhibition. Many growers have already entered, and, including the £15 donation, above £50 has been already subscribed.

WORK FOR THE WEEK.

KITCHEN GARDEN.

But little out-door work can now be done where snow has fallen, and it has done so pretty generally; men should therefore be employed about such work as can be done within-doors, which I have already pointed out. Set traps for mice, and destroy all vermin. Look after the crops of Peas and Beans in the ground. See to the manure heaps, prepare road-scrapings and charred refuse; and mix the rubbish wheeled from the vegetable ground with salt. This will form a valuable manure for the land. If possible do not employ the same description of manure twice in succession on the same land, a change will produce the greatest results. As soon as the young *Carrots* in the hotbed are about an inch high, thin them out to 3 or 4 inches apart. *Radishes* are sometimes sown on the same bed; when this is the case they should also be thinned out, and when ready for use they must be drawn with care, so as not to injure the tops of the Carrots. Should the weather continue severe, the frames containing young plants of *Cauliflowers* and *Lettuces* for spring supply, and the Cabbage Lettuce for present use, must be covered-up and well protected. *Mushroom* beds should now be made in sheds or houses purposely fitted-up for a spring supply. The horse droppings should be well beaten down, and the bed should not be less than a foot in depth. Temperature-sticks should then be thrust to the bottom in several places and examined daily; when the heat has become somewhat regular and not exceeding 90°, the spawn may be inserted just below the surface, and the bed afterwards earthed-up. Continue, as occasion may require, to cover a portion of *Sea-kale*. *Rhubarb* may also be forced in a similar way.

FRUIT GARDEN.

The general pruning and training of wall trees and espaliers may be proceeded with at all times, except during severe frost. Peaches, Nectarines, Figs, and Apricots are, however, better left for some time yet. Gooseberries and Currants may be planted in rows 5 feet apart, and trained as low espaliers. Where room is an object, this is an economical mode of growing them. These fruits may now have the necessary pruning. Take advantage of frosty weather to wheel manures to such fruit quarters as require that assistance. Newly-planted trees of all kinds should have their roots protected from frost by a mulching of litter or short dung.

FLOWER GARDEN.

The stock of bedding-out plants should now be looked over; if the stock of anything is short remove a portion of it into a warm house to produce cuttings for propagation. It is often difficult in the autumn to procure sufficient plants of some kinds, and cuttings of all the more softwooded plants struck in this and the next month and properly hardened-off, will bloom equally well with those struck the previous autumn. It is, however, advisable that bedding-out Geraniums and other woody plants which require to be of a certain age and size before they are transplanted to the open borders, should have been struck and well-established before winter, as fresh-struck plants of such are apt to grow too fast to produce a fine show of blossom. Be on the safe side as regards numbers, there is rarely an overstock at planting time. In all large places some odd corner is set apart for growing the shrubs and plants most commonly required to fill-up vacancies; where such is the case, cuttings of the more common ornamental shrubs may now be put in, with Honeysuckles, Roses, &c. Every description of plant used for the above purpose should be propagated, and the more showy herbaceous plants should always form a part. The stock of evergreens should be frequently lifted, that their final removal may be effected at any season without risk. In severe weather beds of Pinks are apt to be eaten down to the stumps by rabbits. Many florists' gardens are exposed to this serious disaster; it is advisable to protect the beds with galvanised wire-netting, placing some larch stakes, 2 feet out of the ground, at short intervals round the bed, to which the wire should be fastened. The depredations of rabbits would thus be effectually prevented, and I know of nothing better, even when there is none of these vermin in the vicinity, than a close-meshed wire net as a protection to beds of Pansies, Carnations, Tulips, &c., which are often more injured in spring from cold cutting winds than from frost. The Ranunculus bed should have attention; give it a slight forking over, throwing it up into little ridges; these can be levelled-down at any time previous to planting. Look over the collection of roots, separate the offsets from those which are large enough to bloom for planting in the reserve bed; these will flower splendidly the succeeding season. It is from want of this that we often see large spaces in the amateur's Ranunculus bed without a bloom. Hollyhocks appear to be coming fast into favour, not only as beautiful border plants, but also as a florists' flower for exhibition. Those planted in the border are extremely subject to the attacks of slugs, which greedily feed on the fleshy shoots; a dusting of soot occasionally will make these less palatable. Those plants which are wintered in pots must have the decayed leaves carefully removed. If flowers are required to occupy in spring the beds which are afterwards devoted to the usual bedding-out plants, they will have been planted, and such being the case, some choice ones now pushing may require a slight protection from severe frost. Sawdust, leaf mould, or old tan may be put over the best sorts of Anemones, Scillas, Hyacinths, and Tulips, covering the ground afterwards so as to resemble that of the other beds. The pleasure ground will require frequent sweeping and rolling, the walks to be rolled, especially after frost, and every attention ought to be paid to neatness and order. Deciduous trees and shrubs may now be thinned-out and pruned if necessary; evergreens, however, had better remain untouched for the present. Planting, too, should not be done at this season except in extreme cases, but ground to be planted may now be prepared with advantage.

GREENHOUSE AND CONSERVATORY.

Although it is not yet desirable to shift the general stock of stove and greenhouse plants for a few weeks, under some circumstances a part may require fresh potting at this time. When such is the case room must be made to keep them apart from the general stock for a short time afterwards, as their treatment will be somewhat different. Most softwooded plants require heading-back or pruning at the present season, and this should always be performed a sufficient time before the plant is repotted, in order to enable it to make a fresh growth. It is likewise often necessary, with this class of plants, to disroot them to some extent at this potting, which is an additional inducement to defer repotting till the plant has made sufficient growth—say young shoots an inch long—to enable it to bear the operation without injury. Attend to the training of plants on wires and trellises. Fast-growing plants, such as Tropæolums, will require frequent attention. Cinerarias will now require some assistance in the shape of weak manure water. Watch for green fly, to which this plant is very liable. As the principal kinds of Begonias will now be showing bloom, they may be advantageously removed to the conservatory, previously staking them carefully to preserve their fine foliage from being damaged. In some old conservatories the flues frequently run under the pathway, and are only separated from the bed in which the plants are growing by 4-inch brickwork. Where this is the case it may reasonably be expected that the soil in immediate contact with the brickwork will become dry at the bottom if fires are required, and yet may appear moist at the top; the soil should in such cases be examined frequently, and have water accordingly.

STOVE.

Stove plants will be much benefited by bottom heat and a moist temperature till active growth commence. Thin and tie out the shoots as they advance, to form the plants into the desired specimens, and guard against injuring the foliage. Much of the beauty of plants consists in their having clean, healthy foliage. Dry roots of Gloriosa, and a portion of the

stock of Gesneras, Gloxinias, Achimenes, and other herbaceous stove plants, may now be plunged in bottom heat to start them previously to potting.—W. Keane.

DOINGS OF THE LAST WEEK.

When writing on Saturday week the snow had all gone, and it has disappeared again on this the 14th, after quite as sudden a thaw; but the frost during the week has done more injury than the more severe frost preceding it, as even a day or two of mild weather, after an attack of frost, makes the plants more sensitive afterwards, and requires more care and consideration on the part of the gardener.

KITCHEN GARDEN.

Though we used litter and laurel branches when this week's rost set in, we fear that some of our earliest Broccoli and our earliest Cabbages have suffered considerably, even though we took these means to keep the frost from them. Lettuces and Endive of any size have also suffered a little, all plants from the previous mildness of the weather being full of juices and tender. We trust that when the weather changes there will be less injury than we imagine, but it will be prudent to sow some Lettuce, Cabbage, and Cauliflower in a slight hotbed, or in boxes in heated houses, so that any loss may soon be replaced. As yet Brussels Sprouts and the different Borecoles have stood well. The greater portion of our Savoys were used, but a number of heads of good size, though protected by the snow, have been injured in the heart, and therefore will be of little use.

We are rather surprised that so many of our cottage gardeners seem to have no relish for *Borecoles*, as Cottagers' Kale, Scotch Cabbaging Kale, and Brussels Sprouts, as they stand the winter when Broccoli seems to have a hard fight for it. We hear sad complaints amongst our cottager friends, who live in low positions, as respects their Broccoli, which they will persist in planting largely. True, a fine large Broccoli is a regular fill-pot, and is something for a family to come and go on, but when you cut the head it is all that you generally get, for we suppose, on the same principle, few of our cottagers care about the Sprouting Broccoli, which yields such an amount of produce; whilst, on the other hand, with Brussels Sprouts and the Kales it is cut and come again without end. When once the top is gone—and what can be more sweet after the frost has just mollified them a little?—there is no end to the shoots and sprouts from the stems. Though for a definite purpose we are fond of such Kales as the Scotch Cabbaging and Veitch's Dwarf, yet for a cottage garden we think there is little better than the tall Scotch Kale, as the supply from the stems in the spring months is next to inexhaustible, and well cooked they are not inferior to flavour to the best Broccoli. We so far join with Dr. Johnson as to have a high regard for the Cauliflower, but frequently we have found young Coleworts excel the most compact Cauliflower in delicacy of flavour.

We shall not have written these few lines in vain, if thousands more of our cottage gardeners be induced to grow more of these hardy vegetables, which nothing but a winter close on zero seems to kill. We fear that one reason why these hardy vegetables do not occupy almost every part of a cottage garden in winter is, that so frequently they are so badly cooked as to be both unpleasant and unwholesome to the person who eats them. With all the good properties of our English housewives, and in some respects we consider them unequalled, we fear that, as respects simple cookery, the statements made by a French refugee lady in the papers lately have too much truth in them. We have not been much in the habit of going to great dinners of late, but when we have gone to public, or at least large dinners on public occasions, it has often surprised us how difficult it was to get a well-cooked Potato; and the vegetables were so hard and yellow, that in the summer we have been glad to fall back on a little salad, or a simple bit of Lettuce, which the *artistes* in the vegetable department could not spoil. It is, therefore, not to be wondered at, that our simple lasses in the country do not know how to make the most of the hardiest health-imparting vegetables. A few lessons from the French lady, or any other lady, would be of importance. We fear that in this frosty weather, serious illness has been caused by cooking frozen vegetables before they have been thoroughly thawed in cold water. In such a condition they are next to poison. We know that in some hard limy waters it is not easy to boil vegetables jelly-soft without wasting them, or to prevent them turning out of a dirty yellow instead of a rich green; but even in such water a pinch of carbonate of soda will make the vegetables retain their proper colour, and the soda would do no harm to anyone. We like greens to be served green. Others may have them as yellow as they please.

But for the weather we should be thinking of putting Peas and Beans, and even a few Potatoes into the ground. We must forward them under a little protection. We were so far glad that we had a store of Sea-kale, Rhubarb, and Asparagus up as we could raise none during the week, the ground was so excessively hard; trenching and digging therefore were quite out of the question. These winter vegetables forced, along with Mushrooms, help us very much in the winter season, when we have less variety out of doors. Their goodness very much depends on their texture.

Mushroom House.—We have made our first bed in our renovated house, rather late as it happens. The bed was made chiefly of long litter, with a mixture of droppings, as they came from the stable, turned over and watered until it became about half as much decomposed as the old gardeners would have required for a Cucumber bed. It will soon be fit for spawning, when an inch or two of droppings will be added on the surface. A little dry turfy soil was added to help to consolidate it. Before commencing, the ceiling was run over with a thin coat of oil and anticorrosion paint to prevent condensed moisture resting there, and as all the platforms are of wood well seasoned, which, with the exception of the spars for the bottom of the beds, we shall expect to last at least twenty years, we had the whole, with the exception of the spars, coated three times with anticorrosion paint to keep the damp out. If the wood had not been so thoroughly dried and well seasoned, we should have preferred retaining it in its natural state, but nicely planed. We are quite sure that under some circumstances wood will last longer unpainted than painted. Painting green unseasoned wood is one of the best means of securing premature decay from dry rot and internal fermentation.

Something would be gained in this direction if the simple fact were more acted upon, that wood will last longer when always dry or always damp than when frequently exposed to extremes of wetness and dryness: hence it is next to incalculable how long sound piles of wood will remain sound when kept several feet below water-level. A good oak post will remain sound for many years when kept in a pretty equable state as respects moisture under ground—much longer than the bulk of the post above ground, subject to greater alternations of heat and cold, dryness and wet, and the wasting influence of the air on each crack and cranny. But the greatest and the most rapid decay takes place close to the surface of the ground, because there the greatest extremes of dryness and wet are the most frequently experienced.

We have hinted above that we had our Mushroom house repaired, and not too soon, as on a cold snowy morning during the week we lost the old thatched roof of the old shed from which we have obtained large quantities of Mushrooms. We fear the beds bearing will have been greatly injured. The roof was picturesque enough in its worn-out mossy condition, and we felt sorry to lose it, and all the more, as we cannot be sure as to how. It is just possible that there might have been a live cinder in fresh soot placed there the night previously, but if so, nothing was seen until morning, and then, wet as the outside of the roof was, it was soon in a smouldering state from end to end. It is also possible a spark from a tobacco-pipe in dry litter might be the cause. We can never be too careful in little matters. We should not like to interfere with the lovers of "the weed," but we do know that many smokers are excessively careless of lucifers and sparks from their pipes. When we have it on good authority that men will be heedless enough of consequences to smoke even in a powder manufactory, we need not be so much surprised that there will be smoke amongst combustible materials in farms and gardens. All such carelessness is very reprehensible, and we have no doubt disastrous consequences frequently ensue. There are right times and right places for doing most things. There are men who seem to have a pleasure in doing a thing just because it is forbidden to be done: hence the zest with which a stolen pipe, as it were, is smoked because the time and place are strictly forbidden. These stolen pipes are the dangerous pipes. There is often gross selfish injustice in such practices. We have travelled in railways much less of late, but now, since for the accommodation of smokers there are smoking carriages, why should almost every carriage be tainted with tobacco, to the discomfort of those who detest it, whilst the smoking carriages are seldom filled? When we went to the great show at Oxford our clothes

were tainted for twenty-four hours. More than half the passengers in crowded ordinary carriages smoked heavily the whole way, without the slightest apology, whilst we noticed that the smoking carriages were not half filled. Now, we will only say, that be a smoker a garden labourer or a gentleman, there is nothing manly or honourable in smoking in a wrong place. A man worthy the name of man would scorn to realise a paltry pleasure which he saw to be a cause of discomfort and often of injury to others.

FRUIT GARDEN.

We have done little except in the way of pruning, watering a Peach house beginning to push, cleaning and pruning other houses, and taking more Strawberry plants into a little heat. Unfortunately the mice have attacked the buds again, notwithstanding all precautions. It is very annoying after getting fine plants. Beginners in setting their potted plants in houses would act wisely in using no saucers until the flower trusses appear strongly. Stagnant water at the bottom at an early stage, and saturating the buds with water, make a wreck of many a fine Strawberry pot. In moving the plants into houses all the old outside leaves may be removed, and a little fresh surfacing given. The bottom of the pots should also be examined to see that the hole is not clogged up outside, which it often will be if the pot has stood on the gravel. All forcing, where very early produce is not required, should go on but slowly in such weather. Where Peaches happened to be in full bloom during the last three weeks, how great must have been the disadvantage as to their setting well, with scarcely a blink of sun to cheer them! We shall be later with many things than usual, owing to changes in the houses—heating, staging, &c.

ORNAMENTAL DEPARTMENT.

Here, out of doors, the work has chiefly been confined to sweeping walks, and pruning Laurels, Ivy hedges, &c., burning the mere rubbish, and using and storing the best for protecting purposes. We have also collected a good store of pea sticks and material for flower stakes—a matter of importance where coverts are sacred grounds in summer—also a good quantity for fire-lighting purposes. As we had to move a lot of cut Black and White Thorn, we did not care to be troubled with it for furnace or other fireplace purposes, so we set fire to a number of loads, and turned it quickly into charred refuse, merely covering it with damp rubbish to subdue the flame, and clearing out as soon as charring was effected. In a few hours we thus obtained some cartloads of charred rubbish, much not better than charcoal dust, but there were many little bits ranging from ⅛ inch to 1 and 1¼ inch in diameter. For all such small wood we find we obtain the greatest quantity of charred material by charring and removing it quickly. For large wood the old mode of covering up with turf and earth is the best, and watching it properly night and day before all the heap is charred, allowing no more air to enter than will support slow combustion.

We have prepared places for propagating, potting, &c., yet we were disinclined to move plants much in such weather, but if the thaw continues, next week we shall do much in this way. Those who are inexperienced have little idea how soon plants suffer from great extremes of temperature, even for a short time.—R. F.

TRADE CATALOGUES RECEIVED.

E. G. Henderson & Son, Wellington Road, St. John's Wood, London, N.W.—*Catalogue of Vegetable and Agricultural Seeds.*

W. Cutbush & Son, Highgate, London, N.—*Catalogue of Vegetable, Flower, and Farm Seeds.*

Butler, McCulloch, & Co., Covent Garden Market, London, W.C.—*Spring Catalogue of Seeds for the Kitchen and Flower Garden, &c.*

Barr & Sugden, 12, King Street, Covent Garden, London, W.C.—*Descriptive Spring Catalogue of Choice Seeds for Flower and Kitchen Garden, &c.*

George Gibbs & Co., 25 and 26, Down Street, Piccadilly, London, W.—*Catalogue of Seeds for the Garden and Farm.*

R. Parker, Exotic Nursery, Tooting, Surrey, S.W.—*Catalogue of Agricultural, Flower, and Vegetable Seeds, &c.*

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

Maud.—A letter is at the post office as "A. M."

Books (*R. Atkinson*).—"The Treasury of Botany" is in the alphabetical form; indeed, its second title is "a popular Dictionary." It is the latest. The price is 10*s*. There are no cultural directions in it. (*W. B.*).—"The Cottage Gardeners' Dictionary," with Appendix, including new plants to the end of 18.7, is price 6*s*. 6*d*., or post free 7*s*. 2*d*.

Journal of Horticulture (*C. M. McCrow*).—No such reduction is made.

Horticultural Directory (*A Young Head Gardener*).—It will depend upon the place you are managing.

Aucuba *J. W. K.*).—The male is similar in leaf to the female Aucuba japonica so long known, usually with leaves spotted with yellow, but sometimes entirely green. *Vera* is merely a nurseryman's addition to the name. *Picta* has leaves with a broad yellow margin. You will find a very full descriptive account in vol. xvi., pages 254, 255.

Waterproofing Calico (*J. D. L.*).—The only composition likely to render your calico jackets waterproof, is Indiarubber dissolved in naptha and then brushed on the calico. A few yards of Mackintosh cloth would have been far less trouble, far more sightly, and not much more expensive.

Parallelogram (*A Subscriber for Many Years*).—To erect a perpendicular line, and find point C accurately, is described in fig. 31, page 447. As line A B is 41 feet 4 inches long, and line BC, 62 feet long, the radii of the circles referred to are determined. From the stake at point C, with a line 41 feet 4 inches long, trace an arc as in point D. From the peg at point A, with a line 62 feet long trace an arc cutting the former one; where the two arcs cut each other is point D.—M. O'Donnell.

Cyclamens (*Welshman*).—We cannot recommend any florist; all the principal florists can supply what you need if you inform them. (*R. McK.*).—We quite agree with you in highly prizing the Cyclamen as a table decoration. You will have seen notes on its general culture in our last week's number.

Epiphyllum truncatum Flowers Drooping (*F. W.*).—We have no doubt that their short continuance in flower is due to the temperature; we would move them to the cooler house whilst flowering, and for twelve months after flowering keep them in the warmer house, removing them only when in flower. When they begin to grow they require a rather moist atmosphere, and should have copious waterings at the root, but avoid in all stages keeping the soil in a saturated condition. When the growth is over, it is sufficient if the soil be kept moist enough for the stems to remain fresh. We do not recognise the plant from the part sent, flowers are necessary.

Snowdrops after Flowering (*Arthenice*).—The plants would be better of a light airy position free from frost, and should be kept in a cold frame until they have been hardened off, and then they should be planted out in the open ground. This is a better plan than allowing the bulbs to ripen in pots. They are of no use for flowering again in pots, but are very useful for borders.

Berberry and Almond Planting (*Idem*).—Both may safely be planted from the present time up to April in mild weather, but the earlier it is done the better.

Centaurea candidissima (ragusina), Iresine Herbstii, and Golden Feverfew Sowing (*James S.*).—Sow the seeds of all early in March, in pans filled with a compost of two parts turfy loam, one part sandy peat, and one part leaf soil, with a free admixture of sand. The pans should be well drained, and the surface of the soil made even and fine. Scatter the seeds regularly, and just cover them with fine soil. Water gently and place the pans in a hotbed of from 70° to 75°, and a top heat of 55° to 75°, keeping them near the glass and the soil moist, but not very wet. Continue the plants in the hotbed after they appear, keeping them near the glass and affording them plenty of air, so as to prevent them from drawing up. When large enough to handle pot-off the Centaurea and Iresine singly in small pots, and the Golden Feverfew in pans, placing the plants about an inch apart; return them to the hotbed, shade for a few days, harden-off when established, and remove to a cold frame but protecting from frost. They will be nice plants by the beginning of June.

Plants for Shady Border (*Wm. R. H.*).—Ajuga reptans rubra, Glechoma hederacea foliis variegatis, Nierembergia rivularis, Sedum anglicum, Saxifraga umbrosa, and Vinca elegantissima, which, though it grows taller than you wish, is very ornamental.

Tea Roses for Forcing (*A Lady Reader*).—It is in our opinion better to plunge the Roses in their pots if wanted for winter forcing, rather than to take them out of their pots and plant them in the ground. We should recommend shifting them into larger pots previous to their being plunged, so as not to have to disturb the roots in repotting when they are brought in for forcing. Put good drainage, and stand the pots in the ground on inverted saucers or slate to keep the worms out. Place them in cold frames as soon as winter frosts set in, and bring them into a light double-span house when they are wanted for blooming, being careful not to force too rapidly at first. They do not require bottom heat, which often causes mildew. The best bottom heat they can have is to be set on open wooden staging with hot-water pipes under.

Tropæolum Jauratti and tricolorum Culture (*Farmer*).—The tubers should be potted in September, or before they begin to grow, in a compost of light fibrous loam, sandy peat, and leaf soil in equal parts, with a free admixture of sharp sand. Good drainage is necessary, and in potting it is well to place the tuber on silver sand. Pot so that it shall be covered with soil. Water so as to keep the soil sufficiently moist, and place the pots in the greenhouse in a light airy position. The shoots will need a trellis or other support.

Geranium Leaves Going off (*H. A. B.*).—The leaves sent us have the appearance of suffering from damp accompanied with cold. Could you not give them a more light and airy position with an increase of temperature? Is there much manure in the compost used for potting, and is the watering no more than sufficient to keep the foliage from flagging?

Mushrooms in a Cellar (*A Subscriber*).—In our number published last 6th of October there are full directions. They are too long to reprint. You can have a copy if you enclose four postage stamps with your address.

Fruit Trees Laid in (*J. J. H.*).—Your several hundred fruit trees laid in the ground will not be injured by the severe weather, if they have not been kept in bundles so that the frost could reach the roots from these being insufficiently covered with soil. We advise you to spread some dry litter over them, and leave them covered-up until the ground is thoroughly thawed. We think they will be quite safe. The "Botanical

Magazine" is published in monthly parts, price 3s. 6d. It may be obtained through any bookseller.

Cistern in Greenhouse (*Subscriber*).—It will benefit rather than deteriorate the air in the house.

Dracæna Leaves Browned (*E. C., Kent*).—The Dracæna leaf seems as if it had had a chill, or been scorched by the sun when damp; but Dracæna leaves, just like those of evergreens, do not last always, but a few are lost every year.

Raising Vines from Eyes (*A Beginner*).—The eyes can be struck in a Cucumber frame, where the pots may be plunged in a bottom heat of 75°, and a corresponding top heat. The eyes may remain until they have not room enough, and should then be moved to a house where they can have a brisk bottom heat and a moist top heat, potting as required. Train the canes from 12 to 16 inches from the glass, and far enough apart to allow them room to develope their foliage. It is not likely if grown with Cucumbers that they would form canes of sufficient strength for fruiting next year, for under such circumstances it is hardly possible to give them the light and air they require to form strong well-ripened canes.

Potatoes (*G. A.*).—Messrs. Barr & Sugden advertise Thomas Almond's Yorkshire Hero, and also Rintoul's New Early White Don, but we do not observe Transell's Seedling down in their present list.

Potatoes for Seed, and Frosted (*R. S.*).—Neither unripe, nor badly grown, nor small Potatoes will do well for planting; in fact, I prefer unripe tubers as seed, and of course the smaller they are the nearer they should be set together, and the closer the rows should be. Thoroughly frosted Potatoes will now be perfectly soft, and the sooner they are separated from those which remain firm, and are cast away, the better. Then the tubers which are firm had best be spread thinly, without touching each other, on a dry floor or upon boards, and be allowed to remain there till they show signs of vegetating, and in that case they will certainly do for seed; but should they show no sign of pushing by a month or two hence, let them be boiled down for the pigs, or otherwise used in the household by those who do not object to discoloured or sweet-tasting Potatoes. The unripe, uglies, and the little ones had better undergo the spreading process in a dry twilight shed, or somewhere secure from frost, and when their shoots are tolerably prominent, scoop away the inferior "sprits," leaving one or two of the strongest eyes from each tuber according to their size, and that will prove a means to secure a much finer and more even crop. This practice is more to be regarded than early planting. —R. Fenn.

Heating a very small Propagating House (*Novice*).—We think that heating by a tank in a house 10 feet by 9 feet, and heating by piping, are both good. Were we, as you propose, to heat the small propagating house by means of a conical boiler, we would prefer having on each side a bed 3½ feet, a pathway of 2 feet, two 3-inch pipes covered with rubble under each bed, and two 2-inch pipes all round for top heat.

Cover for Heated Tank (*Calcaria*).—Perforated zinc will do very well for covering your tank, provided the water in the tank is rarely above 170°. Slate covered with cocoa fibre refuse, if you keep the bottom of the cocoa fibre damp. When it becomes thoroughly dry the heat will not rise freely through it. It looks cleanly on the top, and the heat given to the bottom of the pot is prevented escaping. Clean ashes or sand answer very well in such circumstances, as all the heat comes from the slate. Even in their case, though it may often be advisable to keep the surface rather dry, that next the slate should be moist, which is very easily managed.

Proposed Hot-water Piping (*R. T. B.*).—We prefer No 1, with three flows and one return.

Cucumber House (*T. M., Rochdale*).—You do not tell us whether your house is to be a lean-to or span-roofed. As it is to be 12 feet by 8 feet inside measure if it be span-roofed, we would have a bed of 2 feet 9 inches on each side and a pathway down the centre. If a lean-to, a bed of from 3 to 4 feet wide in front would do, and there might be narrow shelves on the back wall for pricking out seedlings, &c. In either case, for early work you would need two 4-inch pipes below the bed and two pipes all round for top heat—that is to say, to work in the dead of winter. A small boiler would therefore be necessary, but, as often stated, it is always expensive to heat a small place with hot water; but if you regulate the firing by well attending to draught as lately stated, you will minimise the loss of heat by the chimney. If we had to heat such a place for Cucumbers that we did not commence with until the first or second month of the year, we would, in the case of a lean-to house, take a stout flue all round except the doorway, enclose the flue in front of the house for a bed to be placed over it, and leave the back flue exposed for top heat. If you give more particulars we may be able to do better for you.

Converting a Building into an Ice House (*Young*).—By your proposed plan you would so lessen the size of the house if you built the wall inside, that the house would be little more than 10 feet by 6 feet inside. Now it is 12 feet by 9 feet. Were we to make that house into an ice house we would leave it of that size, and sink the floor inside not 3 feet, but 6 or 9 feet, build another wall outside the present house 9 inches from the other, leaving the space between airtight—pretty well as good as stuffing the space with straw or sawdust—and then have a roof of 18 inches of thatch over the present tile roof, and the eaves reaching beyond the outer wall, which outer wall we would cover with as light a colour as possible.

Utilising House Sewage (*A. B. G.*).—We mix the entire sewage of the house by letting it run into a tank, and we apply it in spring and summer by means of a pump, either by hose or bucketsful, to Asparagus, Rhubarb, Cabbageworts, Onions, &c., having gutters made purposely between the rows. In winter, if needed, it may be poured over vacant ground.

Name of Fruit (*Joseph Burgess*).—Hollandbury.

Names of Plants (*J. Wills*).—Physalis Alkekengi. We did not know, until shown by its effect on your writing, that the juice of the fruit totally obliterates ink. (*James*).—We cannot name plants from their leaves only. (*R. Giddings*).—1, Dendrobium Gibsoni; 2, Cyrtochilum leucochilum (*J. J., Romsey*).—Nephrodium molle. (*A. S. B., Norfolk*).—Æschynanthus Paxtoni. (*J. M.*).—The Oncid is O. barbatum. The other we do not yet recognise.

POULTRY, BEE, AND PIGEON CHRONICLE.

INQUIRY.

In reply to Mr. Preston's inquiry on January 5th, I beg to state that at the beginning of October I sold George White, 147, Culford Road, Islington, about fifteen fowls, for which he agreed to give me £3 18*s*. He acknowledged their arrival, and said he would write again soon. Hearing nothing further, I wrote again, when he replied he had mislaid the invoice, and asked for another, which was sent. Afterwards I wrote for the money several times, generally receiving no answer. At last "Rogers" wrote, saying Mr. White was in Scotland, and would not return till December 14th, when my letter should be attended to. Since this date I have written three times on the subject, and received no reply. My last letter was returned, saying he had gone away. Seeing your inquiry, I forward this statement as a warning to others.—C. B.

THE "STANDARD'S" CORRESPONDENT ON CARRIER PIGEONS.

I have thought proper to draw your attention to an article on the Antwerp or Belgian Pigeon which has appeared in the *Standard* newspaper, Tuesday, December 27th, and I believe there is a second article by the same person in a more recent copy of the *Standard*, which I have not yet seen.—R. W.

[In reply to "R. W.," I beg to state that I have read both the letters in the *Standard*. I was glad that such letters should appear in a widely-read daily newspaper, because the wonderful powers and utility of the messenger Pigeons would thus come before the notice of many who are wholly or partly ignorant of such birds, reaching thousands of persons who are entirely out of the range of the fancy and its special organs. Mr. R. W. Alldridge, of Old Charlton, Kent, the author of the letters, wrote them, I have no doubt, with a good motive, but they are not free from error, and a part of his second letter is certainly not written in good taste, and reflects in harsh, and I can venture to say, untruthful terms (doubtless from ignorance) upon Pigeon fanciers. Speaking of the English fancy Carriers, the high-class birds, he says they will not bring up their young; this is a mistake, for they, as all fanciers know, are excellent parents. Mr. Alldridge also errs in regard to first-class homing birds being worth only 1*s*. each. He is also in error as to the preference given by him to young birds, in one case of actually nine weeks old, over birds of mature age. His preference of hens over cocks is also, I think, an error, as well as his objection to using birds while breeding.

But there is a passage in Mr. Alldridge's second letter which I particularly wish to notice; it is this—"For those who care to know all about Pouters, Fantails, and such-like useless fancy kinds—kinds I again strongly advise your readers to have nothing to do with, for I presume I am not addressing members of the 'fancy,' or subscribers to some Pigeon club, held at the Pig and Whistle, somewhere—for such persons there are books published, which they can peruse, and, possibly, derive great satisfaction therefrom. I have never read one, and have not the least intention of doing so, as I am not a 'Pigeon-fancier' in the usually accepted sense of that term, or a Pigeon-dealer." Now, I do not in the least know what position in life Mr. Alldridge occupies, but I can assure him that I, as a clergyman and rector of a parish, and an ardent Pigeon-fancier for life, know the principal fanciers in England, Scotland, and Ireland, and that his sneer at the fancy is wholly misplaced. Very frequently—indeed, it is almost a law in human nature, people most strongly condemn what they least understand. Mr. Alldridge says he has never read books on fancy Pigeons (I possess nearly a dozen, and some very high-priced ones), and most certainly he does not know Pigeon-fanciers. As to the "Pig and Whistle," I remember being present two years since at the annual dinner—rather banquet, of the North British Columbarian Society, held at the Hanover Hotel, Glasgow, where the company consisted of gentlemen of private fortune, officers, merchants, and men of large means and good position. After dinner a handsome piece of plate was presented to the President, and really—really Mr. Altdridge, the whole affair was not of the "Pig and Whistle" kind. Then I received a card of invitation to the dinner of the National Peristeronic Society, held at the dining-room of the Crystal Palace. Mr. Alldridge may call the Crystal Palace "The Pig

and Whistle," but I do not. Indeed, his sneer is wonderfully misplaced. Ladies of title and gentlemen of position are among our Pigeon-fanciers and exhibitors, as any reader of this Journal knows. The odd thing is that, after many years' experience and knowledge of the fancy, the only low-class fanciers I have ever known are some of the fanciers of flying Pigeons. There are artisans who keep them, Dragoons, Skinnums, and Antwerps, and walk out on Sundays to fly their birds. I know the scamps well enough; pipe in mouth, oath on lips, betting money in pocket, workday clothes on, out they walk to spend their Sunday, not at church, but at—"The Pig and Whistle." On the other hand, those who keep high-class fancy Pigeons—Pouters, Carriers, Fantails, &c., usually have them, as I do, for ornaments of a garden and pets for the family. Pigeon culture and Pigeon books are not among things to be despised, though Mr. Alldridge appears to think so, yet he may see how highly men of the calibre of Charles Darwin regard them; *vide* his work on "Animals and Plants under Domestication."

Although the fancy for homing Pigeons has been much in the hands of the lowest class of fanciers, yet I hope even those given to the culture of the high-class varieties will adopt Antwerps for nurses of their Pouters, and that as a means of national defence as well as pleasure this variety will be very extensively bred.

One word more on the mistakes of general writers in regard to Pigeons. In an edition of "Buffon's Natural History," published by Warne in 1869, and "modernised from the most recent authorities," now lying before me, I read at page 184, "The tame Pigeon and all its beautiful varieties is said to derive its origin from the *Stock* Dove, implying its being the stock or stem whence the other domestic kinds have been propagated." This antiquated mistake ought not to have again appeared. Then in *All the Year Round* of November last, in an article entitled "Messengers Aloft," the writer tells us that "the written paper is fastened under the Carrier's *wing*." There are also other gross blunders in the same paper.

In regard to Mr. Alldridge's letters, I again say that I am glad they have appeared, for both poultry and Pigeons ought to be kept, as the present war proves to us, in far greater numbers than at present. I press, therefore, upon fanciers to spread all they can among people generally the utility of homing Pigeons.—WILTSHIRE RECTOR.]

NENTHEAD POULTRY, PIGEON, AND BIRD SHOW.

THIS was held in the new school rooms on the 13th inst. The buildings are admirably adapted for the purpose of a poultry show, being well lighted and very spacious. All the arrangements were very good, and the Secretaries did all they could to add to the comfort of the birds under their care. Mr. James Dixon, of Bradford, acted as Judge.

The first class was Black and other Red *Game*. This was the best class in the Show, and out of the ten pens five were highly commended; the cup for the best pen in the Show also went to this class, and was won by Mr. W. Walton, who took the second prize as well. The cup pen, we learnt, had been successful at several large shows previously. The chicken class contained some very good birds; Mr. Thomas Brown's were capital pens. The Duckwings were all that could be wished for as regards quality, but the entries were small. The *Hamburgh* classes were not good, and none of the birds shown would have had any chance of winning at one of our large shows. The two first-prize *Spanish* pens were good, but the rest in the two classes very middling. There were only seven pens of *Polands;* the prize pens were good, also the highly commended and commended pens. The Game *Bantams* were of medium quality, and only eleven pens were shown. The class for a pair of hens of any breed contained some first-class birds; the first prize went to Game and the second to Spanish, and three pens were highly commended.

The *Pigeons* were for the most part of only medium quality, and as there were only four classes, the entries were not numerous.

Of *Cage Birds* there was a good collection, divided into twelve classes. The cup for the best bird in the Show was awarded to a very good Belgian Canary, belonging to Mr. R. Walton, who also took the second prize in the same class, besides several other prizes in the Marked classes.

GAME.—*Black-breasted and other Reds.*—Cup and 2, W. Walton, Cocklake*hc*, J. Morton, Marley Hill; T. Brown (2); T. Henderson, Craig Nook; W. Liverick, Nenthead. *Chickens.*—1 and 2, T. Brown. *hc*, J. Walton, Annatwall; T. Brown. *Any other Variety.*—1, T. Brown. 2, W. Walton. *Chickens.*—1 and 2, W. Walton.

HAMBURGHS.—*Golden-spangled.*—1, J. Todd, White Lee. 2, J. Morton. *Chickens.*—1 and 2, J. Todd. *Golden-pencilled.*—2, J. Stephenson, High House. *Chickens.*—1, R. Sim, West Cramlington. 2, J. Stephenson. *Silver-spangled.*—1, J. Hilton, Whigglety. 2, Walton & Rutherford, Green Ends. *Chickens.*—1, J. G. Millican, Alston. 2, Walton & Rutherford. *Silver-pencilled.*—2, J. Stephenson. *Chickens.*—1 and 2, J. Stephenson.

DORKINGS.—1, W. Walton. 2, Walton & Rutherford. *Chickens.*—1, W. Bear park, Ainderby Steeple. 2, J. Percival, Nenthead. *hc*, J. Hilton.

SPANISH.—1, H. Williamson, Danby. 2, Bell & Burn, Alston. *Chickens.*—1, H. Wilkinson. 2, J. Wilkinson.

POLANDS.—1, J. Chaplow. 2, W. Bearpark. *hc*, P. Swindle. *c*, R. & W. Walton.

GAME BANTAMS.—1, F. Clementson. 2, W. J. Stewart, Darlington. *Chickens.*—1, W. Wilkinson. 2, J. J. Walton, Alston.

COCHIN-CHINA.—2, J. Dickinson.

ANY OTHER VARIETY.—2, G. H. Savage, Nenthead. *Hens.*—1, P. Swindle. 2, Bell & Burn. *hc*, H. Robinson, Nenthead; W. Bearpark; Walton & Rutherford.

DUCKS.—1, R. Sim. 2, J. Kindred, Bailes.

PIGEONS.—*Pouters.*—1 and 2, J. Guthrie, Hexham. *Carriers.*—1 and 2, J. Guthrie. *Tumblers.*—1, J. Guthrie. 2, R. & W. Walton. *Any other Variety.*—1, J. Guthrie. 2, W. R. Little, Alston.

RABBITS.—2, W. Hewitson, Wesrdale.

CAGE BIRDS.

CANARIES.—*Belgian.*—Cup and 2, R. & W. Walton. *Golden and Silver-spangled Lizard.*—2, J. Guthrie. *Yellow.*—1, R. Walton. 2, W. J. Stewart. *Buff.*—1, J. Robson, Nenthead. 2, J. Dickinson. *Yellow-marked.*—1, R. Walton. 2, W. Hetherington. *Buff-marked.*—1, W. J. Stewart, Darlington. 2 and *hc*, R. Walton. *Green.*—1, J. Guthrie, Hexham. 2, J. Ritson, Alston. *Dun.*—1, J. Stephenson. 2, W. Spark. *Best Couple.*—1, R. & W. Walton. 2, Tatters and Swindle.

GOLDFINCH.—1, J. Guthrie. 2, W. Walton. *Mule.*—1, J. Hind. 2, J. Bayne.

BULLFINCH.—1 and 2, J. Stephenson.

CORK POULTRY SHOW.

THE annual Exhibition of poultry, Pigeons, and Cage birds was held on the 4th inst. in the Athenæum, and was on the whole a complete success. The entire collection far exceeded that of any former year. The collection of Pigeons, although not so numerous as in previous years, was select, and of the highest quality. However, there was a great falling-off in the Cage birds, there being comparatively few exhibited. The following is a list of the prizes:—

SPANISH.—1 and 2, R. P. Williams. *hc*, Lady A. Lloyd; J. C. Cooper. *c*, Mrs. Hay; J. C. Cooper.

DORKINGS.—*Grey*—1, R. P. Williams. 2 and *c*, J. C. Cooper. *Chickens.*—1, J. C. Cooper. 2, T. O'Grady. *hc*, Mrs. Taaffe. *c*, Capt. Dowman. *Coloured.*—1, J. C. Cooper. 2, *hc*, and *c*, Mrs. Hay. *White.*—1, Countess of Bandon. 2, Miss Perry.

BRAHMAS.—*Dark.*—1, G. A. Stephens. 2, J. C. Cooper. *c*, Lady A. Lloyd; T. Babington; J. C. Cooper. *Light.*—1, Capt. Dowman. 2, H. L. Tivey, sen. *c*, Capt. Dowman; Mrs. Hay.

COCHINS.—*Buff.*—1 and Extra 2, Mrs. Hay. 2, W. H. Perrin. *hc*, J. Dowling. *c*, Mrs. Taaffe; W. H. Perrin. *Partridge.*—1, R. P. Williams. 2 and *hc*, Mrs. Taaffe. *c*, J. Topp. *Any other Variety.*—1 and Extra 2, Mrs. Taaffe. 2 and *vhc*, Col. F. C. Hassard. *Young.*—Cup, Mrs. Hay. *vhc*, H. Perrin. *hc*, W. G. Mulligan.

HOUDANS.—1, J. C. Cooper. 2, Mrs. Clay. *c*, J. C. Cooper; E. J. Poer.

CREVE-CŒUR OR LA FLECHE.—1, W. C. Pickering. 2, Viscountess Doneraile (La Flèche). *hc*, G. A. Stephens (La Flèche). *c*, C. Carleton (Crève-Cœur).

HAMBURGHS.—*Spangled.*—1, Countess of Bandon. *Penciled.*—1 and *hc*, T. O'Grady. 2, Countess of Bandon.

POLISH.—1 and 2, R. P. Williams. *c*, J. K. Milner; E. Hobbs.

GAME.—*Red.*—1, G. A. Perrin. 2, P. Ducrow. *hc*, E. J. Poer; T. O'Grady. *c*, Mrs. Taaffe. *Any other Variety.*—1 and *c*, G. A. Perrin. 2, W. Johnstone. *hc*, M. Cramer.

BANTAMS.—*Red Game.*—1, T. O'Grady. 2, G. A. Perrin. *c*, N. E. Wallace; E. J. Poer; Col. F. C. Hassard. *Any other Variety.*—1 and *c*, P. Ducrow. 2, T. O'Grady.

BANTAMS.—*Any other Variety.*—1, L. F. Perrin. 2, G. A. Stephens.

TURKEYS.—1, J. C. Cooper. 2, W. C. Hamilton. *Poults.*—1, J. C. Cooper. 2, Countess of Bandon. *hc*, W. C. Hamilton. *c*, T. O'Grady.

GEESE.—*Toulouse.*—1, J. C. Cooper. 2, R. P. Williams. *hc*, P. Ducrow; W. H. Perrin. *Any other Variety.*—1, J. C. Cooper.

DUCKS.—*Rouen.*—1, R. P. Williams. 2, R. W. Boyle. *vhc*, J. C. Cooper. *Aylesbury.*—1 and *hc*, R. P. Williams. 2, L. F. Perrin. *Any other Variety.*—1, Countess of Bandon. 2, J. C. Cooper.

SELLING CLASS.—1, J. Jeffries (Cochins). 2, Capt. Dowman (Silver-spangled Hamburghs). *c*, Lady A. Lloyd (Silver-pencilled); Mrs. O'Callaghan; Mrs. Taaffe; P. Ducrow (White Cochins); Mrs. Marmion (Spanish); J. Dowling (Spanish); J. Hosford (Dorkings); Mrs. Murphy (Polish); Capt. Dowman (2).

PIGEONS.

POUTERS.—*Black or Blue.*—*Cocks.*—1, J. Lloyd (Blue). 2, J. H. Perrott. *Hens.*—1, J. H. Perrott. 2, F. W. Zurhorst.

POUTERS.—*Any other Colour.*—*Cocks.*—1, F. W. Zurhorst (White). 2 and *hc*, J. Lloyd (Mealy). *c*, J. K. Milner; J. H. Perrott. *Hens.*—1, J. H. Perrott. 2, F. W. Zurhorst (White). *c*, J. K. Milner (Red); J. K. M'Donnell.

CARRIERS.—*Black.*—1, R. W. Smith. 2 and *hc*, J. Jeffries. *c*, F. W. Zurhorst. *Any other Colour.*—1 and 2, J. Jeffries.

BARBS.—*Black.*—1 and *hc*, J. Dowling. 2, J. Jeffries. *c*, R. W. Smith; J. Jeffries. *Red or Dun.*—1 and 2, J. Dowling. *hc*, J. Lloyd (Red). *Yellow or other Colour.*—1, J. Jeffries (Yellow). 2 and *hc*, J. Dowling (Yellow). *c*, W. H. Bennett (Yellow).

OWLS.—*Blue.*—1, W. Johnson. 2, J. M'Donnell. *hc*, J. Jeffries; H. L. Tivy, jun. *c*, H. L. Tivy, jun. *Any other Colour.*—1, J. Dowling (White). 2, Withheld.

TRUMPETERS.—1, J. H. Perrott. 2, R. W. Smith. *hc*, J. H. Perrott; H. L. Tivy. *c*, H. L. Tivy.

JACOBINS.—1, T. O'Grady. 2, R. W. Smith. *hc*, J. Dowling. *c*, J. K. Milner F. W. Zurhorst.

FANTAILS.—1, T. Martin. 2, Master R. A. Blennerhassett. *c*, T. Martin; J. F. Blennerhassett; R. W. Smith.

NUNS.—1 and 2, J. Dowling.

TURBITS.—1, J. Dowling. 2, H. L. Tivy. *c*, F. W. Zurhorst; J. Dowling; H. L. Tivy.

MAGPIES.—1, T. O'Grady. 2, J. M'Donnell. *hc*, R. W. Smith.

TUMBLERS.—*Short-faced.*—1, F. W. Zurhorst. 2, Master R. A. Blennerhassett. *Common.*—1 and 2, J. H. Perrott.

ANY OTHER VARIETY.—1, F. W. Zurhorst (Runts). 2, J. Dowling (Blue Dragoons). *hc*, J. K. Milner. *c*, F. W. Zurhorst (Ice); R. W. Smith (Spots).

SELLING CLASS.—1, J. Jeffries (Barbs). 2, J. K. Milner. *hc*, H. L. Tivy (Black Barbs); J. Jeffries (Barbs) (2); T. Martin (White Fantails); F. W. Zurhorst (White Trumpeters). *c*, W. H. Bennett (Yellow Barbs and Red or Dun); R. W. Smith (White Fantails and Yellow Owls); J. Perry (Nuns); F. W. Zurhorst (White Dragoons); H. L. Tivy.

BEST THREE PAIRS OF JACOBINS, NUNS, AND TURBITS.—Medal, and 3, J. Dowling. 2, J. M'Donnell

CAGE BIRDS.

CANARIES.—1 and *hc*, T. Babington. 2, J. Hosford. *c*, J. Heap.

BULLFINCHES.—1, Countess of Bandon. 2, Miss M. Dowling.

GOLDFINCHES.—1, J. Dowling, jun. 2, P. Keating.

LINNETS.—1 and 2, P. Keating. *hc* and *c*, J. Dowling.

THRUSHES.—1, J. A. Ross.

SKYLARKS.—1, M. Daly. 2 and *hc*, D. Higgins.
ANY OTHER VARIETY.—1, J. Hosford. 2, Capt. Stuart, R.N. *hc*, Miss D. Beamish. *c*, J. Lloyd.

THE NEW YORK POULTRY SHOW.

WE have received the prize list of this Show, which commenced on December 14th, and by it we find that the whole of the President's special prizes for European Poultry were carried off by exhibitors from Great Britain; the great gold medal being taken by Mr. J. C. Cooper, of Limerick; the gold medal by Mr. H. Beldon, of Bingley; and the silver medal by Mr. J. C. Cryer, of Southport.

Mr. Cooper has also taken the *American Agriculturist* prize for the best Dark Brahmas, with six of their chickens; Mr. Leavitt's silver cup for the best pair of Buff Cochins; and in the general prize list is third for Buff and Lemon Cochins, second and third for Dorkings, second for Silver-Grey Dorkings, first for Black-breasted Red Game, third for Brown-breasted Red Game, second for Black Spanish, fourth for Crêve-Cœurs, second for La Flèche, first for Sultans in the Miscellaneous Class, first for Toulouse Geese, first for Sebastopol Geese, third for Rouen Ducks, third for Aylesbury Ducks, and first for Mandarin Ducks.

Mr. Beldon, in addition to the special gold medal, took a special prize for the best collection of Hamburghs, was fourth for Dorking chickens, commended for Duckwing Game, first for Black Spanish, first for Golden-spangled and Silver-spangled Hamburghs, first for Golden-pencilled and Black Hamburgh chickens, first for Black African Bantam chickens, and first for Helmet, Turbit, Magpie, Fantail, Antwerp, and Jacobin Pigeons.

Mr. J. H. Cryer, in addition to taking the special silver medal, was first for Spanish chickens, Black Polish, and Silver Polish; second for Golden-pencilled Hamburgh chickens, first for Silver-pencilled Hamburgh chickens, second and third for Black Red Game Bantams, first for Duckwing Game Bantam chickens, first for Red-legged Partridges, first and second for Labrador Geese, first for Grey Call Ducks; first for Carrier cock, and second for Jacobin Pigeons.

BRECON POULTRY SHOW.

I AM Secretary to the Breconshire Agricultural Society. At a special meeting of the members of that Society held on the 28th May last, to consider the desirability of establishing a show in connection with the annual show, it was decided to grant the sum of £10 to the committee of the poultry show, upon the distinct understanding that no further liability rested with the Agricultural Society. Mr. D. Thomas, jun., and Mr. Phillips, both solicitors at Brecon, were the self-constituted committee of the poultry show, and as such attended the meeting of the members of the Agricultural Society. By their desire I acted as secretary to the poultry show, in which capacity I received a large portion of the entry fees, and duly registered them in the entry book. On the 16th of September last, a few days before the show, Mr. Thomas borrowed the entry book from me, and I have not been able to get it back, although I have repeatedly asked for it. Messrs. Thomas & Phillips themselves entered a number of fowls for competition; the former paid me his fees, and gave me the proper entry forms, but the latter did neither. They have now, or ought to have (for I maintain that the prizes should be the first charges upon the funds), the monies which were taken at the gates on the show days. Lord Tredegar, The Hon. Godfrey Morgan, and Lord Hyde were patrons, and of course subscribed to the funds; but as I have not received anything from them, I presume the committee have. None of the prizes, that I am aware, have been paid. I am being threatened with proceedings to recover the prizes awarded, but I have not sufficient money in my hands to enable me to pay, or I would gladly do so; and the committee will not hand over to me any of the monies in their hands, although they have recently received the £10 from the Agricultural Society.

I am of opinion that, considering all the circumstances, all the monies should be paid over to me as secretary; but still I have offered to hand to Messrs. Thomas & Phillips all the monies in my hands if they will produce to me the entry book, shewing and marking what entries I have received, which they have not yet done, and I cannot think that under the circumstances I should be justified in handing the monies now in my hands to them. Seeing that they have, or could have if not paid, the several subscriptions, the fees for the entry of Mr. Phillips' fowls, the takings at the gates, and the £10 from the Agricultural Society, I make out the funds in connection with the poultry show to be ample to pay all prizes and expenses, and leave a small surplus. Therefore, why the committee should thus throw obstacles in the way of settling the various claims I cannot explain; perhaps they will be good enough to do so.

Thinking this explanation due as well to the public as to the several subscribers and those persons who obtained prizes, I trust you will give it publicity in your next paper.—W. M. BRIEN.

THE YORK RABBIT SHOW.

YOUR correspondent "J. B." has often written to me of his trials as a Rabbit exhibitor, and he also wrote after our Show was over, thanking me for my attention to the Rabbits, stating how well his stock looked when they arrived home, and I really think he might have adopted the same course, and dropped me a line in a friendly way, instead of occupying space in your valuable Journal. After the judging was over my man (himself a Rabbit-fancier of thirty years' experience) said, "Some one has sent his Himalayan Rabbits in a fine box, well divided, and has actually put a pair of Rabbits into one compartment." I asked him to point me out the pen, but he was unable to do so on account of the multitude of hampers and boxes he had had through his hands. Probably it was "J. B.," who must remember we are all liable to mistakes, that had put a pair of Rabbits together in one compartment in packing them off to York. I have heard it said that the most careful men often make the most mistakes. That is the only way I can account for the disaster. I now say this, and say it emphatically, that no pair of Rabbits were ever put together, or ever broke through the partition, for that was impossible at the York Show. Every possible precaution that man could devise was used to guard against any accident of this kind. If the doe has had young ones (and I do not doubt it) it is no fault of mine. The Rabbits were never handled but by Mr. Rayson, the Judge, and the packers. "J. B." says she kindled on January 6th; she arrived at York on December 5th, so that just accounts for it. "J. B." in his careful haste put both the Rabbits together.—M. MILLINGTON, *York*.

BIRMINGHAM TUMBLERS.

"READER" informs us we have omitted to mention two peculiarities in the Muffed Tumblers. We omitted them because they are not worth mentioning, and the birds can be bought at any cage or Pigeon shop for 10*s*. per dozen. True it is that some fanciers who devote their whole regard to flying and working birds, consider they obtain better birds by pairing any colour, or muffed and clear-legged birds together, and so they do; but these men are as jealous of the pedigree of their birds as one who breeds the highest-class fancy varieties. Many of them have had the breed or strain their birds come from for years. Do not suppose we mean they have been inbred for that time, for it is pairing wide in feather and family that gives them strength and vigour for their wonderful performance. To see a kit of this kind would astonish and gratify even one who had a distaste for Pigeons—they must be seen to be understood. These men obtain their cross from fellow fanciers who have been equally careful not to admit any bird without knowing his pedigree. But still the birds are worthless for feather, and their owners even have a prejudice against pretty birds, and a prejudice it really is, for to our knowledge some of the handsomest breed the best working young ones; we have seen them roll and mad tumble in the superlative degree; indeed, the only thing to fear in the majority of the dark-winged varieties is, that they may be too good, and yet at the present time they are long-muffed, and would never break without crossing with a clear-legged bird.

What "READER" means by hazel eyes we do not know, it is a colour we have not seen, but that there are no hazel-eyed Pigeons we are sure. The origin of the black or bull eye, which we suppose he means, on the white-winged Tumblers, would be as profitable to pursue as the origin of the white rump on the Blue Rock. They may come from Holland, Germany, or elsewhere, but we will get rid of them as soon as we can.

We do not disapprove of young England's favourites, but think it far wiser to improve the Muffed Tumblers, to bring them in size and shape to his standard, than to anathematise them as some do. We know of some as small, as compact, as good-carriaged birds as any of old England's or young England's Tumblers; but it is a work of time to discard all the evil and keep all the good of a breed with so many faults as the Muffed Tumblers originally had. We hope to see the Muffed Tumbler take the position that a short time more of cultivation will justify it in asking for.—BIRMINGHAM COLUMBARIAN SOCIETY.

THE FANTAIL.

IN commenting upon this singular variety of Pigeon it is almost necessary that we should preface our remarks by a few observations relative to the present varied opinions held by Fantail breeders, with regard to its characteristics considered of most importance. The conflicting opinions of fanciers have too often been manifested to need more than a passing reference to show the importance of establishing a standard in order to tone down, or settle, if possible, these differences, so that those young fanciers who seek enlightenment as to the real merits may not be discouraged by such contrary opinions as are at present promulgated, and which certainly must be quite as annoying to the fancier as embarrassing to the experienced judge. We do not suppose that all fanciers will follow our standard and depart from their own peculiar views, but we will endeavour to make clear our opinions, and lay them before the fancier to draw his own conclusions.

There appears to us to have been raised a local model in most districts where the culture of the Fantail has been at all cared for, and, as a consequence, we too often find that what one judge has denounced to-day as unworthy even of a commendation, a brother fancier and judge to-morrow pronounces perfect,

and signifies such by the award of a prize. Thus our exhibitions are frequently looked upon, from the fancier's point of view, as mere lotteries—scrambles for honour, or gain, or both, with a result far more gratifying to the wondering visitor than it is to those more intimately concerned. And it is to this reasonable cause, we think, may be attributed the fact that many staunch fanciers fall out of the ranks of exhibitors; and that others less skilled or educated in Pigeonology are deterred from taking part in so hazardous a speculation, and therefore either ride their little hobby in obscurity, or content themselves with such many-coloured spangled mongrels as may be seen upon our English farmsteads or at the poultry-shops in our busy towns, rather than submit to change of fashion or the various flights of fancy to which, as exhibitors, they are so often subjected.

We must not be supposed to be taking to task as referring to any of our qualified judges individually or collectively, for to all persons so engaged we would give our hearty support, and would strive to obtain for them the utmost freedom for their candid views, and also the greatest forbearance for their mistakes, for to such errors the most zealous fanciers or experienced judges are liable. In no variety is there greater allowance necessary than in the judging of a number of pens of Fantails, for in their carriage and deportment it may be truly said they are

as changeable as the shade, and in consequence due allowance should be made. It is simply our desire to settle *great* points and merge *little* differences, in order to bring about a better understanding amongst fanciers and judges with regard to this general favourite.

The following description, then, is the result of our careful study.

Fantails, as all fanciers are aware, and as most of your readers will guess, take their name from the peculiar fan-like shape of their tails, and which is, of course, one of the most important points in the bird, and to which the fancier should direct special attention. But it must also be borne in mind that the Fantail possesses other peculiarities besides its conspicuous tail. It has an eccentric shaking motion of the neck, which has been thought much of by some fanciers—so much, indeed, that this characteristic was once sought for as an estimable point, and in preference to a large and expansive fan. By such admirers they were called "Broad-tailed Shakers."

There have been many strange tales told about this kind of bird which we pass over without notice, but two of the most remarkable we think it well to refer to, as they proceed from eminent naturalists, and may mislead those who seek instruction from such writers. From one of the abovenamed sources we learn that "The Fantail is capable of expanding and closing its tail like," says one, "the Turkey," and another "the Peacock." But this notion must be imaginary; it is contrary to fact, for the Fantail does not even possess the same power over its tail as do the other varieties, for the Fantail cannot close its tail, but can only control the membrane upon which the feathers grow in an upward, downward, and sideway motion, which does not influence the spread of the fan in any way.

Another peculiarity noticeable in this variety is, that in its shaking motion it stands upon its toes, and by its backward jerking also a person unaccustomed to them might suppose it would topple over backward; but as a rule, notwithstanding the extent to which the birds throw back their heads, they should be able to maintain their equilibrium gracefully, and carry erect and at ease the expansive fans with which they are adorned, and by which they are partially overshadowed.

Fantails are, generally speaking, of a strong and vigorous

constitution, requiring but little care in their management beyond providing a suitable pen for keeping them dry and clean, and then, with ordinary attention, they will thrive and prove prolific birds, and good also to rear their young. Plenty of space should always be given, and all nooks and corners avoided, lest they should crush, break, fringe, or wholly destroy their tails. Brick nests on the floor have been found most suitable for these birds. They seldom fly much and cannot fly long; and whatever may have been said about their aërial rudder, powers of locomotion, or high flying under exceptional circumstances, we know well from experience that good Fantails cannot and will not fly much, but that they are the tamest and perhaps the most tractable of all Pigeons.

At present the recognised varieties of Fantails are *White*, *Blue*, *Silver*, *Black*, *Red*, and *Yellow*. Splashed and Saddle-backed ones are numerous, but are only looked upon as mongrels. It is a rare occurrence to find two of these latter kinds alike. There are also *Frizzled* and *Silky* Fantails. White Fantails are by far the most numerous, and amongst them are unquestionably to be found the best specimens.

The *general properties* or qualities of the Fantail are briefly summed up as follows, which, with the aid of our engraving, we hope will be sufficiently clear to elucidate our views. The *head* of the Fantail should be plain—capped ones were once numerous, but are now almost disregarded. The head partakes somewhat of the ordinary elongated shape of the common Dove Pigeon, but with a sudden rise from its small wart or nostril covers to the top of its head, and then as sudden a recedence to its *neck*, which should be slender and of a nice symmetrical curve. The *breast* must be very prominent; the *shoulders* or wing-butte generally hidden from view; the *wings* should suddenly slope from their sockets, and just meet at their tips behind the bird, and trailing, or nearly so, upon the ground; the *back* is very short, as a result of the neck and base of the tail coming in contact; the *tail* should be large and wide-spread, in form three-fourths of a circle, and possessed of three rows of broad feathers, about forty-two in number. The bird must not throw backward its head so as to protrude behind, and thus divide its tail. To fanciers more accustomed to other varieties forty-two feathers for a tail may seem a great many, and so, indeed, they are; but we have known a Fantail to have forty-eight tail feathers, but we prefer a bird possessing qualifications even in a less degree, but in all its integral parts, rather than having solely a preponderating number of tail feathers at the sure sacrifice of an erect carriage, without which many essential and minor points are entirely lost. Our engraving shows the desired combination.

The tail should not only be of a three-fourths circular form, but should slightly incline over the back, but not be aside, nor should it too much overhang, otherwise by its weight the bird's wings are uplifted, the body hanging forward, and the general appearance spoilt.

The *eye* of the White Fantail is dark hazel; the *legs* rather short; the *beak* and *nails* pinkish white; *legs* and *feet* coral red.

To admirers of the expansive, many, and broad-feathered "fan" at any cost, we would again observe that such a point is very desirable, but in our admiration of such a good point we must not forget the proud tip-toe strut, the graceful carriage, and nervous shake, so characteristic of a good Fantail, and without which the largest "fan" cannot be effectively displayed. We have had under our notice too many distorted specimens—toppling forward, and crouching beneath the weight of their bulky tails, their breasts in close proximity to the ground, their pinions crossed and pointing skyward—to adopt such point only as our standard. We should endeavour, as far as possible, to obtain the embodiment of all the essential qualities, of which good carriage plays so important a part; it is the means by which other good qualities are exhibited to advantage.

Blue Fantails are far less numerous than the White, and, as a rule, cannot be procured of such quality. The majority of Blues are of a dingy hue, but there are now many excellent Blue Fans of a good clear colour. Blue Fantails should be of a good, bright, uniform colour, the head and neck feathers of a little darker tint. Across the upper coverts (as in Blue Pigeons generally) there are two black bars; a rim of black is also upon the tail near to its extremity. The *eye* of the Blues must be pearl, the *beak* and *nails* dark.

Black Fantails should be of one uniform tone, and as near as possible jet black; but as yet this desirable object is only occasionally attained. They are much too frequently produced of a bluish black, with oftentimes a faint indication of a bar, which is objectionable, and conclusively shows a cross with a coloured specimen, and however desirable such cross may be to perfect other points, *colour* must assuredly suffer.

The *general properties* of Blues, Silvers, Blacks, Yellows, Reds, Frizzled, and Laced Fantails are much alike; indeed, they should all answer the one general description. Colour of *eye* and *feathering* in each of the *five first named* constitute the differences, and denote the variety to which the birds belong. Red and Yellow Fantails are very scarce. They should be of one even colour, or "self-coloured," and must be free from the slaty grey too frequently visible upon most varieties termed self-coloured. They are held of little value unless they are pure and uniform in colour throughout their feathering. The Reds and Yellows, also, seldom have such expansive tails or such broad feathers as the other kinds; their tails are more frequently of the tundish or shuttlecock shape, and in consequence are not so attractive as the Whites and Blues, but still they command attention from their novel appearance. Silvers are much like the Blues, presenting the appearance of a nearly-washed-out blue, save the bar and lower portion of hackle, which is dark—nearly black.

The *eyes* of the Blues, Silvers, Blacks, Yellows, and Reds should be of a pearlish colour. Good yellow-eyed birds are numerous in each variety (save Whites), but pearl eyes for Blues, Blacks, and Silvers should always be preferred. Of Yellows and Reds we are not so particular, but would prefer *pearl*.

Frizzled Fantails are scarce. They may be described as White Fans with their feathers turned upside down. *Silky* Fantails also present a singular appearance. They much resemble an ordinary specimen partially dried after a bath, but yet have, as their name denotes, a nice silky appearance. Good specimens are of a darkish tint on the eye, wattle, and nostril.

These two last-named varieties are extraordinary-looking birds, command a high price, and attract great attention at our public exhibitions from their very singular and rare appearance. —Birmingham Columbarian Society.

RABBITS AT THE COMING COLCHESTER AND PORTSMOUTH SHOWS.

One of the most pleasing features of the Colchester Show to me, being a Rabbit-fancier, is the sum of £12, offered for the four classes of Rabbits, being the largest amount ever yet given. I am glad to see that the claims of the Variety classes to be placed on an equal footing with the Lops have not been overlooked, the handsome prizes of 40*s.* and 20*s.* being allotted to all the classes. The Rabbits are to be penned singly. The entries are only 2*s.* 6*d.* per pen. I shall enter as many as possible. I have also before me the prize list of the coming Portsmouth Show. Supported as it is by so many of the nobility and gentry of the neighbourhood, and above all patronised by the fair sex, I cannot congratulate the Committee so warmly as I have done that of the Colchester Show. Five classes of Lops are to receive 15*s.* and 5*s.* There is only one class for Any variety, and one prize of 10*s.* The entrance fee in all cases being 2*s.* 6*d.* per pen contrasts very unfavourably with Colchester. It cannot be just to award ten prizes to Lops and only one inferior prize to the Variety classes, and still charge the same entrance fee.—S. G. Hudson, *Hull*.

Torquay Poultry Show. — The prizes offered are very liberal; there are three unusually valuable silver cups, and four prizes in each class, varying from £4 to 10*s.*, and for Pigeons £2 and £1.

OUR LETTER BOX.

Plymouth Show (*An Exhibitor*). — The subject, we think, needs no further comment. Reports are not usually subjects for criticism.

Breeding Golden-pencilled Hamburghs (*O. P. Q.*).—No one is so well able as yourself to judge of the birds you should mate. We can only answer for age, and we advise you to put a cockerel and a hen together, taking care that the last possesses all the points you require, and that the first has no real defect. The grizzled tail is a great defect, and the pencillings should not go round the feather—that has a tendency to produce mossy plumage. With such a hen you should put a scrupulously correct cock.

Unfertile Eggs (*Poussin*).—The result you complain of is not uncommon so early in the season and during very inclement weather. We should set her next eggs with confidence. Frost causes the yolk and white of the egg to mingle. When one becomes rotten life has to an extent been developed and afterwards allowed to perish; hence corruption. Those you found unturned and totally unchanged are termed "clear eggs," and are such as are produced where hens and pullets only are kept. Such eggs are frequently met with in the winter. Temperature has much to do with it. It will not occur again.

Fowls under Trees (*H. K.*).—We fear the confinement has done the mischief. There is nothing in their run to cause it, but if there be a time of year when it is likely to be unhealthy it is now. Snow is always trying, and rain with cold winds causes colds. Catch all that are running at the nostril and confine them. Let only the healthy keep about. If all

your birds are sick kill the worst, try to heal the others; if you succeed get some early eggs of a pure breed, hatch them and rear the chickens. In the warm, dry, summer weather no place is better for them than a copse. Of course your birds have a dry roosting place, and have access to dust and light soil. You must also recollect they want very good feeding at this time of year, the earth yields nothing now. If you care only for eggs keep the mongrels, some of them will get well; but if you care for poultry, keep only enough of them to hatch some pure chickens.

Change of Stock Birds (*Brahma*).—If the cock were changed now we think you may safely depend on his successor being the father of the chickens.

Turkey for Table (*Arthenice*).—Why do you not fatten the bird with the injured eye, and keep the younger for laying? Are you sure it was done by fighting. It may be cold and incipient roup—*raison de plus* for killing her. Her state of health offers no impediment. The young one will be quite old enough to breed from. She will not lay till the end of March.

Spanish Cock's Comb Drooping (*Young Henwife*).—The comb falls from want of condition, or from over-condition, or from hereditary defect. If from the first cause, improved health will perhaps rectify the defect; if from the second, it will not. If from the third, only one treatment is possible—that is, to fasten the comb with silver wire in the position in which it is desired to place it.

Brahma Cockerel Vulture-hocked (*C. W.*).—We consider a vulture-hocked Brahma worthless as a breeding bird, if anything more than an ordinary fowl is required. We kill numbers every year, and sell others at nominal prices only, because they have that fault. A vulture-hocked Brahma has no pretensien to be a prize bird, nor should it be sold as such.

Game Bantam Breeding (*Sworrabs*).—Few persons breed or keep the Black Game Bantams. They were never numerous, and are, we think, as much kept as ever. Their larger brethren, the Black Game fowls, are very little kept or shown. We do not believe it is well for any birds to breed in-and-in. You ask why? Because it is neither good for shape nor constitution. It is destructive of strength, and produces deformity. Game Bantams should not be short-legged, neither should they be stilty. A short-legged Game fowl is an abomination, and a long-legged one a lamplighter. Choose the happy medium.

Spanish Cock's Comb Black (*Berkhampstead Subscriber*).—It is more than probable the Spanish cock's comb is frosted. Rub it night and morning, but especially at night, with strong camphor ointment. The Dorking hen has left off laying because the weather is so cold. We have never been led to believe a Spanish cock is "difficile" in his choice of "compagnes." Powdered chalk is an excellent thing to mix with poultry food.

Roughness in Hens' Legs (*A M'D.*).—Rubbing in sulphur ointment often removes it.

Stewarton Hives (*Idem*).—In "Bee-keeping for the Many" is a description and directions for managing. You can have it free by post if you enclose five postage stamps with your direction.

Various (*Apicola*).—There seems to be no doubt that your stock has died of foul brood. The remaining honey should be drained and applied to any purpose except feeding bees, the combs melted down, and the hive itself, after its interior, the frames, floor-board, &c., have been well scraped, should be thoroughly washed both inside and out with a saturated solution of chloride of lime, and then left unused for a couple of seasons. If yours is a closed bee house the hives will require no further protection during winter. We cannot tell why the stock in your large hive is weaker than that in the smaller one. It may be owing, as you suggest, to the fault of the queen, or it may be due to incipient foul brood or some other cause, which can only be conjectured in the case of a hive with fixed combs, or determined with certainty by internal examination if it be a moveable-comb hive.

Song Thrush and Redwing (*T. H. T.*).—The specific characteristics of the Song Thrush (Turdus musicus) are upper parts yellowish-brown, the head tinged with red; secondary coverts and first row of small coverts tipped with reddish yellow; fore part of neck and breast yellowish, each feather terminated by a triangular brownish-black spot; lower wing-coverts reddish-yellow. Those of the Redwing (Turdus iliacus) are upper parts deep hair-brown, inclining to olive; a blackish-brown spot before the eye, a large whitish band over it; secondary coverts tipped with greyish-white; fore-part of neck and breast white, with longitudinal streaks of blackish-brown and pale brown; middle of the sides and lower wing-coverts light red. In the third volume of Macgillivray's "British Birds" there are full descriptions.

OUR METEOROLOGICAL REPORT.

In accordance with your request I have much pleasure in supplying the first of, I hope, a long series of brief weekly reports on the varying characteristics of our climate. In drawing up the table I have been guided by two leading desires—viz., to give those facts (1) which bear most closely on horticultural and agricultural pursuits, and (2) which will be most useful for comparison to my many friends among your readers.

Perhaps you will allow me to say a few words "for once and for all" respecting the data in the accompanying table; if in any respect I fail to make my meaning clear I will, with your permission, subsequently reply to any queries.

It will be seen that the table is divisible into two portions, the first giving absolute data for nine o'clock each morning, and the second giving the extreme temperatures and the total amount of rain.

The barometrical readings are, as all published readings should be, corrected for index error, reduced to 32°, and to what they would have been had the barometer been at the level of the sea. The use of barometric readings, especially in conjunction with the hygrometer, in indicating coming changes of weather, is too well known to require enforcement, and is of itself ample reason for the insertion of both barometric and hygrometric readings in a horticultural journal. But besides this, the humidity of the air as indicated by the difference between the dry and wet bulb thermometers, the direction of the wind, and the temperature of the soil, exert influences on plants which, carefully noted, would I am sure lead to useful results. Extremes of temperature are not less important, but shade temperatures alone are not sufficient: hence I have added the highest temperature registered by a vacuum black bulb thermometer, of which the bulb is 4 feet above the ground, and fully exposed to the sun; and also the lowest point reached by a very delicate spirit thermometer, which rests on grass. These two thermometers evidently give an approximation to the temperatures to which vegetation is exposed. Last, but not least, is the depth of rain collected by a rain gauge whose mouth is 6 inches above the surface of the ground.

As a good deal of confusion exists as to the date against which certain observations are to be entered, I may, in conclusion, state that, assuming that (as is far the best) observations are made at 9 A.M., it is obvious that nineteen times out of twenty the maximum temperature then read belongs to the previous day; it is therefore to be so entered. Again, the coldest time of the day is usually about an hour before sunrise, therefore the minimum read at 9 A.M. on any given day belongs to that day, and is so entered. Lastly, the rain measured at 9 A.M. was the product of the previous twenty-four hours, of which fifteen belong to the previous day, and only nine to that on which it is measured; therefore the rain, like the maximum temperatures, are always entered one day back—*e.g.*, 33.8, the maximum temperature of the 11th instant, was the reading of the instrument at 9 A.M. on the 12th.—G. J. Symons, 62, *Camden Square, N. W.*

REMARKS.

11th.—Overcast in the morning, snow began at 10 A.M., and from 1 to 1.35 P.M. fell heavily, lying 1½ deep at the latter hour. In the evening, about 8 P.M., another heavy fall occurred, making the entire depth nearly 2 inches, but the snow was very light, and hence, as above noted, it only yielded about one-sixteenth its depth of water, instead of one-twelfth, the usual proportion.

12th.—Overcast in morning, fine evening; barometer 30.229 at 9 P.M.

13th.—Cold morning, roads very slippery; about 7 P.M. a slight fall of rain and sleet, with partial thaw.

14th.—Complete thaw, temperature 14° higher than yesterday at the same hour. Wind began to freshen soon after noon; squally at night.

15th.—Fine early, but wet and uncomfortable after 11 A.M., a little snow mixed with the rain at 3 P.M. Gale at night

16th.—Fair in morning, but heavy rain at intervals all day.

17th.—Heavy rain at 10 A.M., and snow at 11 A.M., wild afternoon, starlight in evening.

The most noticeable feature of the week is the fall of the barometer from 30.229 inch on the 12th, at 9 P.M., to 28.876 inch (1.353 inch) at 8.30 A.M., on the 16th, and its long continuance at very low readings, even at 9 P.M. on the 17th having only risen to 28.990 inch.—G. J. Symons.

COVENT GARDEN MARKET.—January 18.

Prices remain quite stationary, and business nearly so, the chief operations being confined to rough goods, which are tolerably plentiful considering the severity of the weather during the last month. Hothouse Grapes are somewhat in excess of the demand, and large quantities of inferior ones can barely find a market. Potato trade steady.

From observations taken near London during forty-three years, the average day temperatnre of the week is 45.1°, and its night temperature 31.5°. The greatest heat was 57°, on the 29th, 1863; and the lowest cold 8°, on the 30th, 1857. The greatast fall of rain was 0.70 inch.

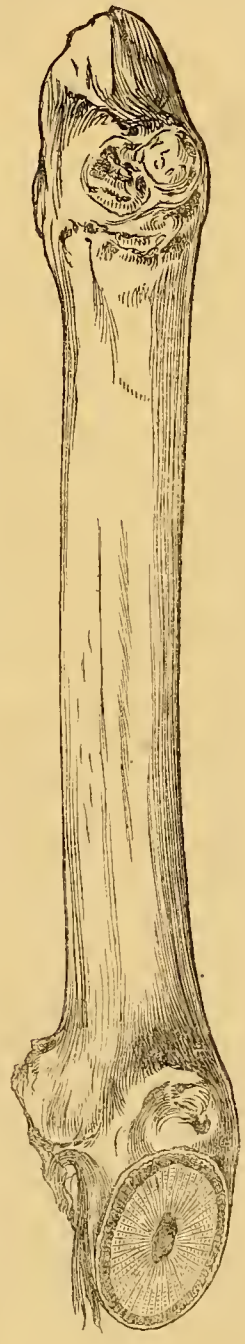
A NEW METHOD OF GROWING YOUNG VINES.

I HAVE for some time felt that our present method of preparing young Vines, especially for planting, is far from satisfactory, and that its imperfection is one of the causes that lead to the sudden decline in fruitfulness so often complained of in the case of the Vine. This being so, and having had to prepare about a thousand Vines for my own planting last spring, I adopted what is, as far as known to me, an entirely new method of growing them; this I will explain in as few words as possible, and those who wish further details will find them in the seventh edition of my little book on the Vine; these, for gardeners at least, will be unnecessary, and amateurs seldom raise Vines from eyes.

My objections to the usual system I had better state to begin with. The first is the rich soil used for growing the Vines. This gives rise to strong soft roots few in number, and which generally perish during the winter. The second is the coiling of the roots, first round the small pot, in which the eye is started, before it is shifted into a larger pot; then the same process continued in the larger pot; and lastly, when the Vine has to be turned out of the pot for planting, the extreme difficulty of distentangling the roots, in which process all the spongioles and small roots are destroyed, leaving a few long bare roots which have to be spread out in the border, reaching a long way across it, and from the points of which the newly-formed roots start, leaving a great part of the carefully-prepared border behind them.

To avoid such evils as I consider these are, I proceeded as follows:—On the pavement of what was intended for and is now a Pine stove, under which are hot-water pipes for giving bottom heat, I placed a complete covering of tough fibry turf taken off a sheep-walk; on this I placed 4 inches of fine fibry maiden loam. In this, at a distance of 6 inches or so from each other, holes an inch deep were made, and filled with white sand, and in the sand the Vine eyes were placed, and just covered with it. The bottom heat did not exceed 60°.

The Vine eyes started in the usual way, and out of sixteen hundred not six failed to make rapid progress. When they were about 9 inches high, with four or five fully-developed leaves, and their first set of strong quill-like roots beginning to interlace each other, I had each plant cut round with a knife, so that it rested on its own isolated bit of turf, and had the points of its roots cut off. They flagged a little for a few days, but soon began to grow again, and I had each plant raised on a square trowel, and transplanted to a similar bed of turf and fibrous loam, but this time they were placed from 9 to 12 inches apart, according to their strength, filling in all round with loam in which there was no manure of any kind. When raised on the trowel, the edges of the square of soil they were growing in was a mass of fine white needle-like roots springing from the large roots that were cut across. The



Vines seemed to suffer no check from their removal, but grew rapidly.

When the Vines were about 3 feet high, and just a week before I meant to plant them in the borders, I had them cut round again, but this time the blocks of loam in which they were growing were from 9 inches to a foot square, and 6 inches deep, and one mass of fine active roots more like those of a Box or Privet bush than of a Vine; they were moved entire to where they were planted with the greatest facility, not a root being injured.

The progress the Vines made after being planted in the borders was, in my experience, altogether unparalleled. The eyes were put in the soil on the 7th of February last, and I send you samples of the wood cut exactly to a day eleven months from the time the eyes were put in the soil. They were chiefly Muscats, Lady Downe's (black and white), Gros Colman, Alicante, and—strongest of all—the Golden Champion. You will note how little pith there is in the wood.

About seven hundred of such Vines as I did not require for planting I had potted for either fruiting in pots or planting, and they have been equally successful; therefore I can recommend the system for either purpose. An examination of the border shows that the roots are retaining the habit thus forced upon them, and are, so to speak, taking their work before them.—W. Thomson, *Dalkeith Park*.

[We received three cuttings from Mr. Thomson, they were of Golden Champion, Lady Downe's, and Gros Colman. No better-ripened, shorter-jointed, smaller-pithed, finer young wood was ever produced on a Vine; and when it is remembered that no more than eleven months before the eyes producing that wood were planted, we believe that such success is without a pa-

rallel. We accompany this with a drawing of a section from the Golden Champion cutting, exactly of the size sent to us.—Eds.]

HOP CULTIVATION FOR ORNAMENT AND USE.

No. 1.

It is not without considerable diffidence that I address myself to a subject which to a certain extent may be thought a departure from the line laid down of treating in these pages only on matters of a purely horticultural nature; I likewise feel diffident in meddling with a subject of which the most experienced cultivators often admit they know but little; but I am emboldened by the fact that if the Hop plant and its culture were better known amongst gardeners it might be introduced more frequently in places where its beauties entitle it to a place. In stating this, I believe I am not using stronger language than will be borne out by all, or at all events nearly all, of those who have seen a plantation of Hops in good condition in August, and I call upon them to say whether they have ever met with anything in the whole vegetable world that exceeded it in grace and beauty. As there seems to be no reason why the beauties of the Hop should be confined to the districts where it is cultivated, it would be well if those having the means would try a plant or two on some suitable spot, and by careful attention to the plant, its beauties would in favourable years well reward the grower for his labour; whilst the interest with which it is regarded where it is not cultivated as a profitable crop also enhances its importance.

Although the cultivation of the Hop on a large scale is limited to a few favoured places, there is no doubt but the number of these might be multiplied, and suitable and sheltered sites in most gardens or grounds might be tried with a stool or two of this plant. I remember many years ago visiting a garden in North Cheshire where there were specimens of Hops in excellent condition, the gardener, I believe, being a Sussex man. I have also seen very fair specimens of Hops growing in a thicket in a situation far from favourable in Northumberland, and I also remember once noticing a Hop hill in the garden surrounding Stirling Castle, but the produce there, as might be expected, was small, the great elevation and want of shelter being felt by other things as well as the Hop, though I have seen fair examples of Hops against the front of a public house in Yorkshire. The Hop, however, as an object of beauty and interest is far from being so widely scattered as it deserves to be, and I think it might often be employed as a summer climber to cover arbours and similar places, and with as good results as other plants used for the purpose, whilst in favourable seasons it would possess an interest which none of the usual plants would have.

The Hop is often met with in Kent in a wild state, but it is not generally regarded as a native plant, for it is supposed to have been introduced from the Netherlands about three hundred years ago. The mode by which our forefathers preserved their beer previous to that time seems not to have been transmitted to us; perhaps it was a secret they did not wish to be too widely known, like that of making beer from the wild Heath, which tradition says the Picts had the means of doing, but the secret died with them. Be this as it may, there is no difference of opinion at the present day as to Hops being an essential component in the manufacture of beer, and whatever else has been used as a substitute for them has always been regarded by John Bull as an adulteration.

It is, I believe, generally admitted that about one-half of the Hops grown in the United Kingdom are produced in Kent, and that Kent and Sussex together produce fully three-fourths of the entire crop. Of those grown in Kent, the bulk comes from the centre and the southern edge of the county, the western, northern, and coast district producing but few. In the districts where Hops are cultivated the diversities of soil are, perhaps, as great as where any other crop is attempted to be grown, the soils varying from the stiff clayey loam of the Weald to the dry chalky downs of East Kent. Plantations of Hops are likewise to be met with on the dry stony soil overlying the limestone, or what is here called Kentish rag, as well as on some peaty marshes by the side of the Medway, where it is necessary to maintain open ditches 4 feet deep, and only 15 feet apart, all over the ground, the height above water mark not admitting of any other kind of drainage. Extraordinary crops are reported to be sometimes obtained from land of this description, but the quality is inferior, the variety grown not having the best name at market; in fact it may be said that the Hops of the best quality are invariably produced on dry land abounding in lime or some of its combinations. Some dry valleys between the chalky downs to the south of Canterbury produce excellent samples, although not better than are often met with from the ragstone slopes facing the Medway. The greater part of the course of that river from Tunbridge to Maidstone is through a district rich in Hop gardens, some parishes presenting as great an area under Hops and fruit together as under all other agricultural crops; and as the ground devoted to the former two is all cultivated by hand, it need hardly be said that a farm or holding of fifty acres gives employment to a greater number of hands than are often met with elsewhere on a farm of many times that extent. The gathering-in of the crop alone gives employment to a greater number of persons than any agricultural crop that I am aware of. Some growers during the past season expended from £15 to £20 per acre in securing their crop. The anxiety with which the crop is watched may therefore be readily conceived, especially when the reader is told how exceedingly precarious it is—so much so, in fact, that it is not unusual for the grower to do the best he can and not realise a single shilling, and that may even be several times repeated; on the other hand there have been now and then instances where a crop of Hops has realised more than would have bought the land twice over, valuable as it often is.

So capricious is the Hop plant that, as mentioned at the beginning of this article, it is not unusual to meet with old cultivators, men who have made the plant their study through life, admit themselves puzzled and fairly beaten when their efforts to avert failure are of no avail; and on the other hand occasionally a recovery will take place in plants that seemed in a hopeless state of disease, and a fair average crop will be produced. These peculiarities in the Hop have no parallel, so far as I am aware, among other crops, the energies of the cultivator being almost as powerless to control the plant's going downhill as they are to stop the Potato disease. At the same time he seldom or never gives up in despair, the Hop-grower, in fact, being one of the most ardent of all cultivators, trying all manner of experiments, and examining his crop daily with a keener inspection than the plant-cultivator whose pets are in preparation for some show, for he will tell you to-day whether his prospects are better or worse than they were yesterday. He does this, not in the way of merely jumping at a conclusion, but as the result of the close inspection of a number of his plants, and he is generally right, though the superficial observer may call his conclusions the result of prejudice.

It is the uncertainty of success that has limited Hop-culture to certain localities, and it is doubtful whether science will ever be able to battle with this uncertainty. Much has certainly been done of late years in freeing the cultivation of the plant from some vexatious restrictions put upon it by those who buy the produce. Still Hops are a capricious crop; and though the past season has been favourable, the preceding three years were indifferent, although the skill and attention exercised were the same in all. The united crop of the three years referred to in many instances did not exceed that of 1870 alone, and there are often enough greater differences than this. Besides, the quantity of Hops really wanted is not very large, and as they deteriorate very much by being kept over a year, the anxiety to sell within a given period has, with other causes too complicated to be mentioned here, placed the Hop market in a condition more fettered and hampered by restrictions than that of anything else I know. Even the removal of the excise duty has not set the planter so free as he ought to be, but time will doubtless effect a reform in an abuse which legislative enactments are powerless in.—John Robson.

DOUBLE-FLOWERED PELARGONIUMS AS BEDDERS.

Not having a sufficient number of one sort of the above class of Pelargoniums to fill a bed last summer, our beds being large, I did not attempt planting any of them out. I have heard poor accounts of their success out of doors, the common complaint being their too vigorous habit, but there cannot be two opinions as to their suitability as pot plants. They are vigorous in pots, but not too much so when properly managed. I grew a large number last summer for the decoration of our conservatory, and those who saw them can testify they were good. They were—Andrew Henderson, one of the best of the

double-flowering varieties, its habit and growth being dwarf and compact; colour clear scarlet lake. The trusses are of extraordinary size, and the individual flowers are very full and double. I have seen nothing of its colour equal to this. Emile Lemoine, extraordinarily large trusses of large and very double flowers; colour carmine changing to scarlet. It is of medium growth, throwing its trusses well above the foliage. I should say it will make a good bedder. Gloire de Nancy, much in the way of Andrew Henderson, but not nearly so good; flowers rich rosy scarlet, growth vigorous. Surpasse Gloire de Nancy and Ranunculiflora plenissima, not worth growing. Victor, a remarkably effective variety, the flowers being of a bright orange scarlet, striped and flaked with white. This is a splendid variety. Madame Lemoine, a shrubby-growing kind with the leaves conspicuously marked with a dark brown zone; a free bloomer. The trusses are immense, the flowers very double and perfectly formed, of a beautiful bright pink colour. This is, of its colour, one of the best double-flowering varieties ever sent out. Wilhelm Pfitzer, an extremely attractive and dazzling variety, producing immense trusses of large double flowers of an exceedingly rich carmine colour. Marie Lemoine, this variety is said to be the same in style as Madame Lemoine, but with the trusses larger, and the habit dwarf and compact. I have not had it long enough to prove it. The other varieties I have proved.

I have now a stock of Madame Lemoine which I purpose bedding out next summer. The number of cuttings required were potted-off in August; each cutting had a thumb-pot. After the cuttings were potted they were well watered, a place in the yard was covered with coal ashes which were made level and hard; on this the pots were placed, no frame or other protection being put over them. The cuttings soon took root, and when frost was expected they were removed to a Melon pit, where they have been kept ever since. I shall have them potted in March in large 48-sized pots; they will be taken into the Peach house to remain until the last week of April, they will then be placed in the yard for a fortnight, and finally removed to the flower garden, where they are to be plunged in the bed in which they are intended to remain for the summer. The pots should be plunged just deeply enough for the rims to be covered. Every plant must be carefully watered before plunging. I expect to restrict the vigour of the plants by the above mode of treatment.

The method is not a new one. About twelve years ago when I lived under Mr. James McIntosh, at Drumlanrig Gardens, plunging vigorous varieties of the single Pelargonium was there practised with good results—in fact, some of those plunged in the beds hardly made more than an inch of wood, and had very small leaves. If any of your readers have tried plunging the double-flowering varieties, I shall be glad to know the result.—C. M. M'Crow.

ICE versus GLASS.

Many of your correspondents like "R. F." (see page 49 of last week's Journal), have no doubt had their attention directed to this subject in a way that has been anything but agreeable during this severe weather. The breakage of glass has been in many places very great. Having suffered a good deal from this cause, perhaps a few of my deductions may be useful to others.

Some years since I drew the attention of your readers to the fact, that much of the glass used for horticultural buildings had never been properly annealed. This is a subject on which many persons have never thought; those who have, know that if glass is allowed to cool quickly after it is made, it is liable to break on very slight changes of temperature. I once heard and saw a large and expensive looking-glass crack across when no one was near it. Tumblers that have not been annealed properly will not bear hot water, and those who have seen Rupert's drops know that hot glass cooled very quickly cannot even be scratched without falling into fine powder. Having badly annealed glass, a person must expect that in time it will all crack. To deal with a respectable firm, and not to be too anxious for cheap glass, is the only way to guard against this worst cause of breakage. Mere thickness is no safeguard, heavy glass if unannealed will break quite as soon as thin. It is very bad economy to use glass however good too thin. I shall never again order glass under 21 ozs. to the foot, it is much cheaper in the end than 15-oz. glass.

Then, again, glass is often used too wide, and in that case it is too weak to carry heavy snow or bear rough wind without breaking. Panes 15 inches wide are as wide as ever ought to be used, and I should prefer 14 inches. A wide lap is also one of the chief causes of breakage; so long as there is a lap it cannot be too narrow. A wide lap holds much moisture, and as ice occupies more space than water, such moisture when frozen must lift one pane up or press the other down, and in cold weather the glass will not bear this without breaking, even when good in quality. Some will say, "Why have any lap at all? Place the edges together merely, and if cut level they will keep out the water." My answer is, that in stormy weather a roof so glazed will admit water at every joint, as I have proved. Of course, a very flat roof is a cause of breakage, as more water is retained by the laps of the glass, and more snow accumulates on it. But I have proved that the greatest preventive to breakage by frost is to cut the glass to a slight curve instead of a straight edge. However slight the curve may be it causes all the rain to run down the middle of the pane, thus drawing it away from the putty—a most valuable effect; but in addition it prevents the moisture resting between the laps, because as it collects at the lowest part of the curve its weight overcomes the capillary attraction of the lap, and it runs off, or rather down. In my new houses in which I have adopted this plan, there is not one pane cracked with frost to twenty in those where the straight-cut glass has been used. Now, this great improvement costs little to carry out, next to nothing in fact. The curve being very slight, it is little more than removing the corners of the panes. The trouble to the glazier is nothing, because it is only cutting to a slightly rounded edge in place of a straight one. In addition to these advantages a house so glazed has a much better appearance than one glazed in the ordinary manner.—J. R. Pearson, *Chilwell.*

SETTING OF GRAPES.

After reading Mr. Pearson's excellent and useful article under the above heading (see vol. xix., page 509), I came to the conclusion that it might be of benefit to the amateur at least to know a little about the setting of the Grapes referred to by me on the previous page.

Taking them as there described, Grizzly Frontignan is the first, and requires no attention beyond a gentle shake when the flowers expand, and the same remark holds good as regards Royal Muscadine, Buckland Sweetwater, and Foster's White Seedling, Black Hamburgh and Frankenthal I never set artificially, as I find no need for it. Mill Hill Hamburgh with me was a bad setter, and shanked as well. In the late house, which receives little heat, I find no difficulty with Trentham Black and West's St. Peter's; but Lady Downe's, Alicante, and Barbarossa [Gros Guillaume] require a brush to be run over them, and should also be planted at the warm end.

My treatment of Vines when in flower is very simple, though I do not affirm it would do for Vines in flower now or earlier, but those flowering, say in March, have the benefit of more light and sun than those flowering earlier. When I see the Vines are about opening the flowers I cease syringing overhead, but maintain a moist atmosphere by keeping the troughs full of water, and by damping and syringing the floors and walls, for I do not consider anything is gained by keeping a dry atmosphere. Should the weather be unfavourable or unsettled I use a little extra fire, so that I may give more air at the back and a little in front, taking every advantage of sunshine to admit more air. I also leave a little air at night at the back. Where bees are kept every means should be taken to entice them into the vineries. I have frequently carried in both bees and blue-bottle flies, and shut them up for a few hours; the flies, though not extracting the honey, must do much good by disturbing the foliage. Should there be any cutting or searching winds at the time the Vines are in flower, it is better to dispense with the front air. With me the setting of the above Grapes is an easy matter, and they are very suitable to those who require quality rather than quantity and size, and especially to the amateur.

After reading Mr. Pearson's notes, I wish I had room for Mrs. Pince and Muscat Hamburgh, though I am afraid they would require more heat than I should care to give. I should like to hear how Golden Champion succeeds in Lancashire; I intended having a Vine of it in the summer, but was dissuaded, being told it was a bad setter—in fact, partaking, as Mr. Pearson says, of the Canon Hall Muscat. I have not seen it in fruit myself.

I have endeavoured to show the treatment of my Vines when

in flower in a few short lines, and in summing up the points to be observed, I put down the following:—1st, Withhold water from the top when in flower. 2nd, Maintain a moist atmosphere, though the degree of moisture will be regulated by the weather outside, as it is not good policy to keep the house so damp in wet as in fine weather. 3rd, Keep up a regular temperature, which should be 5° higher during setting. 4th, Give air back and front as weather permits, shaking the Vines gently from time to time.—Stephen Castle, *Bent Hill Gardens, Prestwich.*

EARLY AND SECOND-EARLY POTATOES FOR LIGHT AND HEAVY SOILS.

"Novice," I will presume, wishes for information having regard to production for market purposes; then there cannot remain a doubt about the Early American Rose being the "heaviest cropping" early; and the Early Goodrich (an American white and rather coarse-looking sort) as a second early would beat Paterson's Victoria in that respect both upon light and heavy soils; only when they are grown on the flat on the latter description of soils they will scarcely do to present upon the dinner table. Give them light soil, or plough and plant them upon the ridge system on heavy soil, and then he will get bountiful and very eatable crops, which few, except connoisseurs of Potatoes, would find fault with.

Paterson's Victoria is a better kind than either of the above to grow upon light and heavy soils, but it does not come in so early. In regard also to "heavy cropping," your correspondent has done right to procure Sutton's Red-skinned Flourball as a late sort, but he will do quite wrong to grow it upon the flat in the generally heavy soils of his neighbourhood, which I know quite well. It has the faults of the American kinds so grown in England—namely, a soddened look and a flavourless quality, which the best of cooking cannot rectify; but when grown on a light soil, or upon the ridge, it will produce a great bulk of large, white-fleshed, floury-looking Potatoes, which, as I said before, will satisfy most people, but which a Paterson's Victoria would distance for flavour. Rintoul's New Early White Don, as a heavy-cropping, good-flavoured second-early, would be well worth the attention of "Novice," and I do not think he need care to trouble himself with more sorts than those enumerated.

Messrs. Sutton sent me other American sorts, &c., which I proved on different descriptions of soils, but the Early Rose, the Early Goodrich, and the Red-skinned Flourball were the cream of the lot.

"Novice" also requests you to send him any "works" you have on Potatoes. Allow me to propose that you should send him nearly a quarter of a century's Journal of Horticulture with the index complete. He will there be enabled to learn a good deal more, I fancy, about Potatoes and their cultivation than any "works" at present extant would be likely to teach him. At page 55, in my answer to "R. S.," I have been made to blow both hot and cold at the same breath; drop the first, third, and fifth n's of the first sentence, and then the reading will prove correct.—Robert Fenn.

VIOLA CORNUTA ALBA.

I do not think this valuable little bedder has been brought under the notice of your readers; I consider it one of the best of the bedding plants which have been introduced during the last two or three years, especially as we are so short of such plants having white flowers. Where I am, it is a difficult matter to get the Madame Vaucher section of Geraniums to bloom freely enough to make a good display; and notwithstanding all precautions, as mixing plenty of soot with the soil, strewing soot over it, dusting with sulphur, top-dressing, giving plenty of water, &c., we can only obtain a week's or a fortnight's bloom from the white Verbenas before they are smothered with mildew. Oh for a white Verbena with the habit and the free blooming of Purple King and its twin brother Crimson King! I had beds of these two that were splendid, and I only wanted a white variety of the same habit to accompany them. Cannot Mr. Perry or Mr. Eckford raise us one?

The white Viola admirably fills up the wide gap in unfavourable situations. I had four small circular beds of it, with Coleus Verschaffelti in their centres, and they were pronounced charming by all who saw them. I shall hold this to be my best white bedder until I get some of the white-flowering variegated Geraniums. I think this Viola is best raised from seed every spring, as plants from seed grow much stronger, come into bloom later, and continue longer in flower than those raised from cuttings. I find the beauty of the plants propagated in the latter way is over before the other bedders are at perfection. I found last year that many of the old plants and those from cuttings died off. I should like to know if this was general.—J. T., *Maesgwynne, South Wales.*

INSIDE PARIS.

It will interest many of our readers to know that Dr. Hogg has received by balloon post, from Paris, a letter dated January 7th, from M. Henry Vilmorin, a name widely known and much honoured in the world of horticulture. M. Vilmorin says—"We were leading a happy contented life when all was suddenly disturbed, our household broken up, my wife sent far south, my brothers called to arms, and I remained here alone. I cannot give myself as an instance of peculiar misery, yet see what has fallen to my share. I had to leave Verrières, leaving all my usual work incomplete, many things were lost of course, and studies were broken, making much work already done useless. Several most important collections of ours will be more or less completely lost. Now the Prussians are at Verrières, but we hear that the place is turned into a military hospital and not much damaged. Les Barres also has been occupied, and perhaps is still so.

"My wife left early in September, and went with our little daughter Elizabeth, to Dax. Maurice joined in August the 6th Battalion of Garde Mobile de Seine et Oise, to which he belonged, although never before drilled, or even armed. Philippe had to go to Cherbourg in the beginning of September to enter the corps of Marines. I have heard only once from my wife since she left, she was well and baby, and so was Philippe, but we were not told where he was. As a married man, I am only in the Garde Nationale, and being mounted act as *estafette*. We seldom ride out of Paris. Our service is very safe, and sometimes very interesting; we like it and find that the hardest thing is to get food for our horses. It is very unpleasant also to be stormed at with shot and shell in our houses, as is the case now. I sincerely hope that no wider difficulties will arise out of the present unhappy war, and that your country will be able to settle peaceably all the impending questions at the Conference."

MONPLAISIR AND OTHER TEA ROSES.

Your correspondent on Tea Rose culture (page 43) wishes to know something about Monplaisir; he complains of its shyness, and raggedness when open. When this Rose was introduced I planted it as I plant the rest of my Tea Roses—that is, in a bed fully exposed to the sun, but well sheltered from all winds, and I had then the same complaints to find as your correspondent. I could not get it to open in the house nor out of doors; it certainly was of better shape outside than under glass. The following year I potted early a large plant in a pot that would only just hold the roots, with plenty of drainage; and a month before I turned my bedding plants out I plunged Rose and pot where it was to stand, with, I am glad to say, much better success. I do not think I had more bloom, but what I had opened well, and when that is the case you see a magnificent Rose both in form and colour. Monplaisir is a seedling from Gloire de Dijon, but how fertilised I do not know; the growth is very vigorous, and so pleased am I with it, that I intend planting six more. Evidently it does well if the roots are pot-bound, and from my experience I advise your correspondent to try my plan.

I do not agree with your correspondent in planting his Tea Roses facing the east; my estimate of these Roses is to give them a fully-exposed open situation, away from winds, and in the very hottest and driest time of the summer to give plenty of water, and occasionally liquid manure. It is also a good plan after planting to cover the beds or borders with very rotten dung to the depth of 4 inches.—Rosa odorata.

SPAWN OF MUSHROOM BED ECCENTRIC.

Upon looking through my Mushroom house this morning, I find that the bed which was made about five weeks ago is almost entirely covered with spawn in the shape of white "thread-like" mould. In some parts where the lumps of

spawn were deposited, thousands of little Mushrooms the size of pin heads are pushing themselves up one above another. I have grown Mushrooms for years, but never before saw such masses together. My question is, Would it be advisable for me to put more soil on the bed, or will the Mushrooms now pushing up come to maturity without further aid? My house is about 9 feet wide, lean-to, walk 2 feet wide down the centre, beds each side 3 feet 3 inches wide by 1 foot 4 inches deep. A flow and return pipe runs round the house, inside, at a distance of about 2 feet 6 inches from the bottom of the bed. The beds were made of two-thirds good horse droppings, and one-third maiden soil, well mixed. I spawned in pieces 4 inches apart. —D. W., *Sheffield.*

[In such a case the fresh moulding would not be advisable. We would take a clean hard hair broom, leave the knots of young Mushrooms you allude to, and sweep off clean all the spreading spawn besides on the surface of the bed. Most likely the bed will then produce. We have had several such instances, and adopted the treatment stated.—Eds.]

SELECTIONS OF GRAPES.—No. 2.

Vines in Heated Houses.—These houses may be of several descriptions—viz., 1, Greenhouses and other structures used for plant-growing and storing plants in winter, the borders being, as a rule, wholly outside. 2, Vineries used as store-houses for plants in winter and for growing them in summer, but with the borders inside as well as outside, the Vines being planted inside. 3, Vineries proper, by which I mean that Grapes are treated as the sole object, or, if other subjects are introduced, these are such as will not interfere with good Grape-cultivation.

1. *Greenhouses or Houses Employed for Plant Culture Winter and Summer.*—These have the borders outside, and generally are only suitable for the hardiest sorts and such as may be termed summer varieties, for, from the moisture caused by the plants and the borders being outside, the late-hanging kinds cannot be preserved from premature decay. *White Grapes.*—Chasselas Vibert, berries round, large; strong grower, and free-bearing. Foster's White Seedling, berries roundish-oval and of good size. Buckland Sweetwater, berries round, large; great bearer. General della Marmora, berries large, round; great bearer. *Black Grapes.*—Frankenthal, berries roundish-oval, bunches and berries large. Black Prince, berries oval, long bunches. Black Champion, berries roundish-oval, long bunches; it is earlier than the Frankenthal by about a fortnight. Trentham Black, berries large, oval. Black Hamburgh, berries roundish-oval; free-bearing.

The above are the kinds I have found succeeding best in entirely outside borders and in houses devoted to plant-culture, but with Vines for shade and utility. Of course there are many other kinds that succeed tolerably well in outside borders, but from their liability to spotting and shanking I think it best to omit them. I am aware that not very long ago outside borders were the rule, but now they are the exception. No one will advocate outside planting. It may sometimes be a necessity, but in no case is it advisable. Good Grapes were grown with Vine roots in outside borders; now we have a better order of things, and if no finer Grapes are grown we know they are obtained with greater regularity and certainty.

2. *Vineries used as plant houses*, but with borders partly inside as well as outside, the Vines planted inside. It is almost unnecessary to say that all the varieties named for outside-border-planting will answer admirably, and are what I advise for planting a house intended to afford Grapes in July, the Vines being started early in February; and to those named I would add—White Frontignan, berries round, medium-sized, with the full Frontignan flavour; free bearer. Muscat Hamburgh, berries oval, black, with Muscat flavour. Bowood Muscat, berries large, oval. The last two do fairly in the same house with Hamburghs and succeed them, but are best in a house by themselves along with other kinds requiring a higher temperature; therefore for a supply in August, September, and onwards, if there is a house for an earlier crop, the following are excellent—viz., Muscat of Alexandria, berries oval, well known; Bowood Muscat; and White Tokay, berries large, oval. These are white Grapes. Black kinds are Black Muscat of Alexandria (Muscat Hamburgh); Mrs. Pince, berries oval, a fine late kind, but good in September or when ripe; Black Alicante, berries roundish-oval, bunches large; Lady Downe's, berries oval, large; West's St. Peter's, berries large, roundish-oval; Mill Hill Hamburgh, berries round, large. The foregoing even with plants, keep until the New Year, the best two for hanging being Lady Downe's and Mrs. Pince.

Although plants may be grown in a vinery, there are times when it would be better both for the plants and Vines if the former were removed; indeed it is hardly possible to ripen Grapes perfectly without a dryness of atmosphere which is unfavourable to plant culture. Therefore, as soon as the Grapes change colour remove all plants in active growth, but such subjects as Gloxinias and Achimenes, which need heat with a drier atmosphere for ripening the growths, may remain with advantage. I find no place so good as a vinery in which Grapes are ripening in July and August, for ripening off Amaryllids; and these do not interfere with the ripening of the Grapes, for they need no water, or but little. It is also the best place for ripening the growths of winter-flowering Begonias. The moisture necessary for plant-culture is not only detrimental to the ripening of the Grapes, but also injuriously affects their keeping and the ripening of the wood. If the wood were properly ripened we should hear less of the bunches curling up like tendrils and of bad-setting kinds needing artificial aid. As a rule, there are but few evils to which the Vine is subject that do not originate from the immature growths of the previous year.

3. *Vineries.*—In these the borders are inside and outside the house, the Vines being planted inside. The varieties may be divided into three sections—viz., Early, Midseason, and Late.

Early varieties, or those which bear forcing well, and can be depended on to give Grapes of fine quality by forcing from March to July inclusive, are the following:—Buckland Sweetwater; Foster's White Seedling; Trovéren Frontignan, berries roundish-oval, large bunches; White Frontignan, which ripens in the same house a fortnight before Buckland Sweetwater, but is not so fine a Grape as the Trovéren, which is, undoubtedly, the finest of all the Frontignans; Golden Hamburgh, berries roundish-oval, large; Golden Champion, very large bunches and berries, and as free-bearing as the Black Hamburgh; Black Champion; Black Hamburgh; Frankenthal (Pope's, or Victoria Hamburgh); Duc de Magenta, berries oval, large bunches; Royal Ascot, berries oval, bunches not large, but very free-bearing. All these force well. I have omitted the Royal Muscadine, as I consider it superseded by Foster's White Seedling. For the successful forcing of Grapes I consider it well to have heated borders, especially if part of these are outside. For very early forcing, and where there are no heated borders, have the Vines in pots. Those which answer well for early forcing in pots are Buckland Sweetwater; Early Smyrna Frontignan, berries round, not large, but very early; White Frontignan; and Early White Malvasia, berries oval, but somewhat rounded, a great bearer. These are white Grapes. Of black kinds I would have Frankenthal, Black Hamburgh, Black Champion, Royal Ascot, and Duc de Magenta. It is desirable that pot Vines for early forcing should have the pots about three parts plunged in a bed of leaves or other fermenting material, but it will answer if the pots be set on hot-water pipes, though in a bed of fermenting materials the roots extend beyond the pots, and the produce is larger and finer.

Midseason Grapes, or those affording a supply from July to October, I would divide into three sections—viz., Muscats, Frontignans, and those having none of the Muscat or Frontignan flavour.

Muscats can hardly be produced in good condition before July. I would have Bowood Muscat, Muscat of Alexandria, Muscat Escholata, perhaps identical with Muscat of Alexandria, but if there is any difference, it is in the berries being more even-sized, and the bunches stouter; Tynningham Muscat in no way different from that excellent Grape the Bowood Muscat, but with berries larger than the Muscat of Alexandria, very often pear-shaped, and deeper in colour when fully ripe; Black Muscat of Alexandria (Muscat Hamburgh); Mrs. Pince; and Madresfield Court Muscat, berries, oval, large, jet black, with a splendid bloom. The last two are very valuable for hanging late, exquisite in flavour when fully ripe, and never finer (nor, indeed, are any of the Muscats) than they are in August and September.

Of Frontignans—Trovéren Frontignan, the finest of all. Duchess of Buccleuch, berries round, not large. White Frontignan. Chasselas Musqué, berries round, undoubtedly the richest-flavoured Grape in cultivation. It is liable to crack, but that may be obviated by grafting on the Grizzly Frontignan. Black Frontignan, berries round, small, bunches long and tapering. Purple Constantia, berries round, larger than Black Frontignan. Grizzly Frontignan, berries round; free bearer. The Frontignans require a dry, warm border, especially when

ripening, and to ripen perfectly they require a high temperature, especially by day, a dry atmosphere, and, of course, abundance of air. From their liability to crack the berries should be well thinned. The border may with advantage be formed of one-fourth chalk, in lumps from the size of a walnut to that of a hen's egg.

Other kinds, neither Muscats nor Frontignans, I must again divide into those not requiring much heat, and those which do.

Kinds not requiring strong heat are—Black Hamburgh, Frankenthal, Black Prince, Duc de Magenta, Trentham Black, and Black Champion, all black; Buckland Sweetwater, General della Marmora, Golden Champion, Golden Hamburgh, and Foster's White Seedling, all white or slightly amber-coloured. These ripen in August if assisted with a slight fire heat during March, and later in cold periods and when ripening, constant fire heat not being necessary for successful ripening.

Kinds requiring heat are—Mill Hill Hamburgh, a fine Grape, the finest of all the Hamburghs; West's St. Peter's; White Tokay; and White Nice. These require a temperature averaging 5° higher than is necessary for the Black Hamburgh and the other varieties just named.

Of late Grapes, the Muscats must take precedence. I recommend Muscat of Alexandria, Bowood Muscat, Mrs. Pince, and Madresfield Court Muscat (the first two are not in good order after Christmas—all four I would have in a house by themselves); Lady Downe's; Black Alicante, berries roundish-oval, large, also bunches; West's St. Peter's; Burchardt's Prince, berries oval, medium-sized, bunches long; Barbarossa [Gros Guillaume], berries round, large, enormous bunches; Trebbiano, berries oval, large, bunches enormous; Syrian, berries oval, bunches largest of all; Calabrian Raisin, or Raisin de Calabre, berries round, large; Royal Vineyard, berries round, medium-sized, bunches long.

The Syrian, Trobbiano, and Royal Vineyard, may be objected to on account of their poor flavour. In my opinion the Syrian when well ripened is as good as many others, and it and Trebbiano, for variety of dessert, are indispensable late in the season when there is no other white kind so good as Trebbiano. Royal Vineyard on the same score is also excellent for late purposes. White Nice is well worth growing, though it is not so good in flavour as many, yet its enormous bunches always command attention whether on the Vine or at the dessert.

In conclusion, I would direct attention to the advisability of, as far as practicable, growing in one house only kinds requiring a similar temperature. Frequently we see an extensive vinery planted with nearly every kind of Grape, and some not doing so well as they otherwise would had the house been divided by a partition of glass, and the varieties requiring least heat placed in one part, and those needing most heat in the other. There can be no objection to this arrangement, as the expense of a division is but trifling, and the modifications needed in the heating apparatus will not involve an expense that should deter anyone from adopting the separate system. It is owing to mixed planting and growing in one vinery kinds requiring different temperatures, that some kinds have not their proper place in popular estimation. For instance, Canon Hall Muscat is rarely seen in good condition, and its companion Black Damascus is little better. Both have one fault—*i.e.*, non-setting. What would they be were they grown in a house by themselves, their roots in a heated border, and with a temperature 5° higher than is given to Muscats?—G. Abbey.

OBTAINING MOIST HEAT.

I have a small propagating frame inside a warm house, with a flow and return round the house, and I have enclosed part of one end of the pipes with bricks, and put a frame on the top, covering the pipes with blue slate to support the soil for the cuttings; but I find it is too dry, and burns up the cuttings before they are rooted. I thought of having a zinc trough filled with water to fit inside the frame on the pipes, say 6 inches in depth, and then to put the slates on the top to obtain a moist heat. By having a tap at one end I might take the chill off the water before watering.—Young Beginner.

[You can have all the moist bottom heat you want by merely running a waterproofed rim round the slate, say 1 inch deep, cover it with small pebbles, and on that set the pots, with what plunging material you think best—not to make heat, but merely to retain it. A small pipe will enable you to keep the slate and the pebbles moist. Your proposed substitution of a small tank will answer, but if you cover the top securely your heat will be as dry as from the slate. With a tank, a cover of zinc or plate iron pierced with holes would be best.—Eds.]

SLOW COMBUSTION AND ECONOMY IN FUEL.

My house is a span-roof, 17 feet long and 9 feet wide, heated by a flue which runs round three sides under the stage. There is no ashpit door, and no damper. I at first tried stopping up the ashpit opening, after I had obtained a good fire, by loose bricks, slates, or anything else that came to hand. This answered pretty well, but I could never thoroughly depend upon it. Occasionally I found a too vigorous fire, and the thermometer inside registering 70°; or the fire burnt quite out in a few hours. The plan I now adopt answers much better. I leave the ashpit always open, and thoroughly cleared out. I obtain a good, large, bright fire, and keep it bright if the thermometer is lower than I wish it to be, until it rises to the desired height, which it will do in a very short time; I then throw on four or five shovelsful of fine ashes; I prefer the ashes wet if the night is likely to be cold, as they burn rather better than if dry. If the weather is mild, and I am anxious to keep the heat down, I use dry ashes, and leave the furnace-door about 2 or 3 inches open. I have frequently so left my fire at six o'clock in the evening, and found it still alight at three o'clock the next afternoon, and a nice steady heat maintained.—X. Y. Z.

[There are many roads leading to one place. We know your plan will answer, but it is a wasteful one, as when a furnace-door is left open, the air that freely passes over the fire cools the flue, and there is a consequent loss of fuel. We approve of getting-up the desired heat at once, and then having a slow combustion where a regular heat is wanted in continuous frosty weather. Why not secure the same result more easily and better by having a common, close-fitting ashpit-door, when you can regulate draught? You need no damper for a flue then. We generally use ashes for hacking-up.—Eds.]

CONSEQUENCES OF THE WINTER.

Now that the effects of the severe frost are pretty well known and felt throughout the country, it will be interesting and profitable to report from various parts to what extent we have suffered, and the lowest degree of temperature registered.

On the night of the 23rd of December our thermometer fell to 1° Fahrenheit, and on the 24th to 1° below zero. On both days we had a heavy fall of snow to the depth of 1 foot. Common Laurels, Aucubas, and Laurustinus are all severely injured—not a green leaf to be seen on them, and it will be a difficult matter to know how to cut them until the new growth commences. The Deodars are all severely injured, and must lose all their leaves, and I fear many of our choice Roses will be killed; a fine plant of Maréchal Neil on a south wall is killed, while one on a north wall appears to be unhurt.

What will most affect us at present (and to this I wish to draw particular attention), is the loss of our vegetable crops, as Broccoli, Savoys, and Brussels Sprouts. Cabbage stalks are all killed, and we are glad to bury them to get rid of the unpleasant smell. Young Cabbages which were well covered with snow are injured, but will recover if milder weather come.

Any suggestions which can be offered by your correspondents as to the best and quickest method of providing substitutes for the losses we cannot repair, will, I am sure, be thankfully received by those who may have suffered to the same extent as we have done here in East Kent. I will conclude these few remarks by suggesting a substitute for Peas, which I have heard of and am about to try—that is, to sow any common Peas in boxes in heat, and use the young green tops as a vegetable.—William Anderley, *The Gardens, Bourne Park, Canterbury.*

The Cabbage.—The close-headed variety, which is now more peculiarly called Cabbage, was for many years imported into England from Holland. Sir Anthony Ashley first introduced its cultivation, and made the English independent of their neighbours for a supply. This planter of Cabbages likewise made his name known by other deeds less creditable to his character. It is related that he had a command at Cales (Cadiz), where he got much by rapine, especially from a lady who entrusted her jewels to his honour; whence the jest on him (like on Butler about the spoons, whether true or false). The saying is, that he, Sir Ashley, got more by "Cales" than by "Cab" and Cabbage. As tailors are said to be fond of

"Cabbage," may not this circumstance have given rise to the accusation of "cabbaging," when cloth entrusted to them was appropriated to their own use? It is recorded that Cabbage was first introduced into the North of Scotland by the soldiers of Cromwell. Scotland is more peculiarly the "land of Kale." Old Scotch songs point to the fact. The poet says:—

"There's cauld Kale in Aberdeen,
An' castock's in Stra' bogie."

These castocks are the Cabbage stems, having the fibrous parts peeled off, and the remainder softened by boiling. Sauer krant, that excellent preparation of the Germans, is merely fermented Cabbage.—(*American Gardener's Monthly.*)

[The tradition can be traced far back towards the time in which Sir A. Ashley lived. There is a globular reticulated figure on his monument in the church of Wimborne St. Giles, which the tradition says was intended to represent a Cabbage, and it certainly is more like the globular heart of a Savoy than a "cannon ball," for no artist would represent this even for effect with a netted surface. A correspondent who wrote about the monument in *Notes and Queries* says:—"Evelyn, in his "Acetaria," calls Sir Anthony 'Sir Arth. Ashley, of Wiburg St. Giles.' He says:—'Tis scarce an hundred years since we first had Cabbages out of Holland; Sir Arth. Ashley, of Wiburg St. Giles, in Dorchester, being, as I am told, the first who planted them in England.' 'Acetaria' was published in 1699; so that, according to Evelyn, Cabbages were first brought to this country about 1599, between which date and 1627 (when Sir A. Ashley died) they had been introduced by him into England."—Eds.]

CUTTINGS OF EVERGREENS FOR BEDS IN WINTER.

I WONDER if any of your readers have adopted a plan of making bare beds cheerful in the winter by filling them with evergreen cuttings? The effect in comparatively small beds is admirable, and I am sure anyone who tries this plan would be astonished to find how long they keep fresh and bright in the winter. I would strongly recommend a trial where evergreens are available. Aucubas, Laurustinus, Hollies, Ivies, common and Portugal Laurels, variegated Holly, Carnation cuttings, and innumerable other plants which will suggest themselves to the horticulturist, will be found most effective for such winter decoration. The snow on my beds has now entirely thawed, and I was greatly astonished to find how the cuttings had withstood the hard frost to which they had been subjected; in fact, they look as fresh now (January 17th) as though they had just been inserted.

I first saw the plan adopted upon an extensive scale in a friend's garden, and his gardener informed me that the cuttings are placed in the beds immediately after the bedding plants have been removed and the bulbs planted, and that they remain quite fresh until the spring bulbs appear.—HORTATOR.

TREATMENT OF CAMELLIAS.

REFERRING to the latter part of the communication by "RUSH," (see vol. xix., page 469), respecting Camellias, I wonder at any one turning Camellias into hot pits when making their young growth. I have just had brought under my notice the case of a batch of young Camellias which were put in the Orchid house for the last two years when they ceased flowering, and the consequence is that one-half of them have no flowers now, and they are but a trifle larger as plants than they were two years since. I do not wonder at this, as let a plant remain in a temperate greenhouse or conservatory, when it is ready it will grow—that is, of course, everything else being suitable. And in addition to objecting to turning Camellias into heat I object to the use of peat. The best Camellias I ever saw were those for which no peat was used.

With regard to turning Camellias out of doors, I believe in most cases it is done as a matter of convenience, for in the case of large plants in tubs, &c., there is seldom a house suitable for their reception with the exception of the conservatory, and where the family remains at home in the summer they are placed out of doors on the plea of not being gay. I turn the large plants from the conservatory out of doors, because my vineries are not large enough to hold them. This is done simply as a matter of convenience, knowing that they would be better under cover. I can fully endorse the statement of "RUSH" as to the buds being more liable to fall from plants which have been out of doors, especially if not housed before the heavy drenching rains. This is a subject on which too much cannot be said.—STEPHEN CASTLE, *Bent Hill Gardens, Prestwich.*

ECONOMY OF FUEL.

I LIGHT my fire, putting on a little coal so as to make a nice fire, having all the dampers out. When the water is hot, I put on fuel which I have previously prepared, and which consists of the dust and chips of the coals used in the household. I take the dust mixed with cinders and damped a little. I fill my stove up to the top, close the slide that goes over the ash-pan hole all but an inch, also pushing in another damper, which goes in at the elbow of the flue-pipe, allowing about an inch for the smoke, but, of course, this requires attention to keep the flue-pipe free from soot. I also clear out the clinkers. I always make it a rule the last thing at night—say, at 10 o'clock, to stir up the fire and clear out the clinkers. With this management the fire lasts eight hours, burning regularly, and leaving nothing but clinkers in the fireplace in the morning, whilst the temperature of the house in the morning is 40°. Should it be a severe frost, I rise about 7 A M., go down to the stove, clean it out, stir up the fire, and add a little wood and a little small coal. My management of the stove is on the eight-hour system, and I consider my heating costs only my own trouble, for the ashes used to be taken away. Now that I have the boiler I have them sifted, and I no longer see wasted, as with my neighbours, lumps of nice coal not burnt out which by a little management can be used.—A. B.

[A small house like yours requires, no doubt, personal attendance to heat it economically with a boiler. In many such cases a pipe from a kitchen boiler would be sufficient. We are glad you have succeeded so well. We have no doubt the water-barrel so frequently running over the roots of the Vine causes the berries to crack. Why not move the barrel, or take a large-enough pipe from it into a drain, or away from the border?—EDS.]

ENTOMOLOGICAL SOCIETY'S MEETING.

THE first meeting of the new year was held at Burlington House on the 2nd inst., the President, Mr. A. R. Wallace, being in the chair. Amongst the donations to the Society's library received since the last meeting were the continuation of Sepp's beautiful work on the transformations of Lepidopterous insects by M. Snellen van Vollenhoven, the twelfth volume of Mr. Stainton's work on British Tineina, and the "Entomologists' Annual" for 1870, edited by the same author.

Mr. Butler exhibited a series of Lepidopterous insects recently received from Fantee, in tropical Western Africa, by Mr. Swanzy, including apparently new species of Godaria, Eurynome, Mylothris, and Belenois, species of which two last-named genera of "Whites" appeared to Mr. Butler to mimic each other. Mr. Bates, however, considered the apparent mimicry to be simply the result of the close affinity of the species. A beautiful new Moth of large size, allied to the Saturnia lucina of Drury, was also contained in the collection, which Mr. Butler proposed to name Brahmæa Swanzyi. Mr. Boyd exhibited a variety of Colias Edusa in which the black spot of the fore wings was obliterated.

Professor Westwood described a Geometrideous larva, of which he could find no published description, which he had observed boring a cylindrical hole into Rose buds in the summer. He also noticed that Sepp had illustrated the parasitism of a two-winged fly of the genus Anthrax upon a Moth belonging to the genus Agrotis (A. porphyrea). Hitherto the genus had been supposed to be parasitic only upon bees.

A paper containing descriptions of five new species of Diurnal Lepidoptera by Mr. Hewitson was read.

A specimen of Plusia interrogationis, taken by Mr. Jenner, was exhibited by Mr. Verrall.

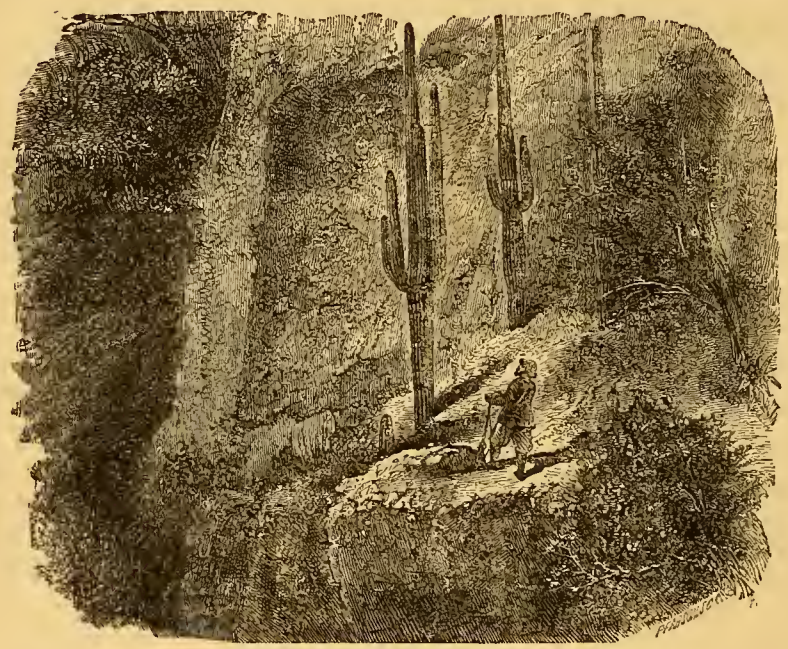
ANOMALOUS PLANTS.

NEARLY thirty years have passed since I was walking, during the cool of the evening, in the Botanic Garden of Calcutta, with its genial curator, Dr. Wallich. We had rested under that tree—a grove of itself—the Banian, and talked of "Giant Plants;" we had gazed on the Amherstia, admired its pale green foliage, pendulous clusters of pink flowers, and long, slender, weeping branches waving before the gentle breeze, and we agreed that it is the worthiest representative of "Graceful Plants." It was our humour then to note such representatives, and we visited the Plantain and Cotton shrubs as worthy members of the "Useful Plants," and the Upas, of fabled power, yet worthy by its virulence to represent "Poisonous Plants." At length we returned to the house, and as we passed the trelliage arched over the steps by which the Ganges is reached, I made some observation on the beauty of the flowers

of the Night-blooming Cereus with which the trelliage was partly covered. "That," observed the Doctor, "represents 'Anomalous Plants.'"

I think that evening's stroll and fanciful grouping of plants had not recently been remembered by me until, walking round the Horticultural Society's conservatory at South Kensington, I came to two cases of "Anomalous Plants," a gift to the Society from Dr. Waggett. They contain exclusively species of the natural order to which the Night-blooming Cereus belongs—the Cactaceæ. The remembrance thus awakened led to a reference to notes made at the time of relative observations by Dr. Wallich, and extracts from works to which he referred me; and these would have again slumbered had I not seen in *Nature* an engraving of the Cereus giganteus, taken from Mr. Bell's book, published by Messrs. Chapman & Hall, entitled "New Tracks in North America."*

Most characteristic is the title, "Anomalous plants," applied to the Cactaceæ. Of the five hundred species, less than a dozen have any leaves, and that dozen belong to one genus, Pereskia, the Barbadoes Gooseberry—they are all stems and branches, and these assume most "anomalous" forms. They are globular in the Melocactidæ, Melon Thistles; they are columnlike in the Cereideæ, Torch Thistles; and they are planiform in the Opuntiæ, Prickly Pears. They vary in size from a few inches to 40 or more feet; some creep along the soil's surface, and others are as erect and high as maypoles. Leafless and thus without the usual means of absorbing moisture from the rains and dews, yet they are among the most juicy of plants, retain their succulence in the hottest climates and the most parched soils, and are there the chief sources of refreshment to men and animals. This and other characteristics of the Cactaceæ I find in the following extract from M. Meyen:—



Cereus giganteus.

"Nature has tried to make up for the imperfections in the form of these plants by the profuseness and splendour of their flowers, for often it seems as if their whole effort was to produce the greatest possible quantity of the gorgeous flowers, with which they are so often completely covered. The extraordinary effect on the physiognomy of vegetation, which is produced by the contrast of the Cactus forms with the other groups of plants, is seen not only in nature, but also everywhere in our gardens.

"In Chili and Peru there are wide plains, which for vast distances, are covered solely by groups of pillar-like Cerei, and thus present a singular and striking, though cheerless prospect. In the Llanura de Rancagua, lying to the south of the Rio Cachapual in Chili, only a few Caven-bushes (Acacia caven, *Mol.*), grow amongst these Cerei, which are often covered with the scarlet flowers of Loranthus aphyllus, from amongst which hang the long, white flowers of the Cereus. When travelling in the interior of Chili we often bivouacked near these Cerei, and their dry woody cylinders furnished the best fuel for our fires. The wood of these plants attains a thickness of 1 or 1½ inch, and the whole cylinder is as much as 12 or 15 inches in circumference. The wood of the Cactus is applied to the most various purposes in the treeless regions of the western coast of South America. As it is very light, it is carried up the Cordilleras, and on the plateaux, which lie far above all arborescent vegetation, doors and beams are made of it without any previous working.

"The columnar Cacti ascend high up the Cordilleras. I have found them on the Cordilleras of Southern Peru, close to the equator, above the heights of 7000 and 8000 feet, and these are also the most beautiful forms which I have ever seen."

Among these is the Cereus giganteus, or Monumental Cactus, which is thus noticed by Mr. A. Smith, in "The Treasury of Botany":—

"It is the Suwarrow or Saguaro of the Mexicans, the largest and most striking species of the genus. It is a native of the hot, arid, and almost desert regions of New Mexico, extending from Sonora, in lat. 30° N., to Williams River, in lat. 35° N., and found growing in rocky valleys and upon mountain sides, often springing out from mere crevices in the hard rock, and imparting a singular aspect to the scenery of the country, its tall stems with upright branches looking like telegraphic posts for signalling from point to point of the Rocky Mountains. While young the stems are of a globular form, gradually becoming club-shaped, and ultimately almost cylindrical, and from 50 to 60 feet in height, with a diameter of about 2 feet at middle height, and gradually tapering both upwards and downwards to about 1 foot. They are most frequently unbranched, but some of the older ones have branches, which issue at right angles from the stem and then curve upwards and grow parallel with it. The stems are regularly ribbed or fluted, the ribs varying in number from twelve to twenty, and have, at intervals of about an inch, thick yellow cushions bearing five or six large and many smaller spines. The flowers are produced near the summit of the stems and branches, and are about 4 or 5 inches long, by 3 or 4 in diameter, having light cream-coloured petals. The fruits are about 2 or 3 ins. long, of a green colour and oval form, having a broad scar at the top caused by the flowers falling away; when ripe they burst into three or four pieces, which curve back so as to resemble a flower. Inside they contain numerous little black seeds imbedded in a crimson-coloured pulp, which the Pimos and Papagos Indians make into an excellent preserve; and they also eat the ripe fruit as an article of food, gathering it by means of a forked stick tied to the end of a long pole."

Referring again to M. Meyen's work, he remarks:—

"In perfect contrast to the long, slender form of the candelabra-like Cacti, are the spherical genera Melocactus, Echinocactus, and Mammillaria. These plants are spherical, having warts and spines arranged in a stellate form regularly distributed over the whole surface; they are often of enormous size, and are seated directly on the barren ground, or in the clefts of bare rocks. These singular plants seem to thrive best in the most desert regions, where all other vegetation ceases; and in hot countries, where almost all vegetation disappears during the dry season, they are as fresh and green as at the time when there was the greatest abundance of water. As their succulent tissue contains a great quantity of watery sap, they are eagerly sought after and sucked by the thirsty animals, which roam over the dry deserts of South America. In kicking off the prickly coat, these animals often injure themselves so much that they can no longer move about, and at last die. At times when there is a want of water, travellers usually open these juicy plants, which have been called the springs of the desert, with their knives, and thus enable the animals to enjoy the sap without danger.

"Just as characteristic are the great unshapely and many-branched Tunas; the Cactus Ficus-indica, *L.* and Opuntia Tuna, with its long spines, are the best known forms of this group of the Cactaceæ. These plants have found their way to Europe, in the south of which they are now naturalised. In Europe as well as in America they are used for making fences, and there is, perhaps, scarcely anything which answers this purpose better, for they have even been successfully applied to

* Messrs. Chapman & Hall have obligingly enabled us to illustrate our correspondent's notes with that engraving.—Eds.

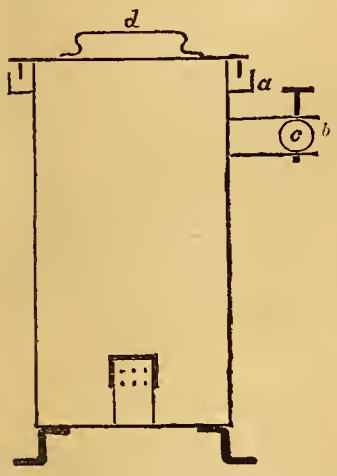
the purpose of military defences—viz., as chevaux-de-frise. Their cultivation is of the greatest importance in desert and barren countries, as they delight in the very driest soils, and not only produce an abundance of edible fruit, but also a considerable quantity of firewood. These Tunas hedges are also need for breeding the American Cochineal insect, and are planted in some provinces of Mexico to a very great extent for this purpose, as formerly the exportation of cochineal from that country was very large."—G.

SLOW-COMBUSTION STOVE.

As some of my friends have had stoves made upon a model I devised about two years since, and as they report very favourably of them, I think it possible some of your readers may be interested, and perhaps helped, by an account of my experience.

About two years and a half ago I constructed a greenhouse entirely of wood and glass; length 10 feet 6 inches, breadth 9 feet, height 9 feet to the centre of the pitched roof. The question of heating it arose as the winter drew on, and I gave an ironplate worker an order for a stove, the performance of which I will presently describe. Having improved upon the first model, I append a sectional drawing of a better form which has been made recently.

The body of the stove consists of a cylinder of sheet iron 6 inches in diameter, in fact a length of 6-inch iron pipe. Its height is 2 feet. The bottom has one opening in the centre, admitting air to a piece of gas-pipe 1½ inch in diameter, 4 inches long, and capped at top. Upon the screw at the lower part of this gas-pipe are two nuts, one fitting above the bottom and the other below; these fix the gas-pipe into its place. The upper part of this pipe (not the cap), is bored by fourteen holes about one-quarter of an inch in diameter. The lid of the stove fits loosely; and outside the pipe and around the upper part is secured, by soft solder, a zinc gutter about three-quarters of an inch deep and the same in width. This, when the stove is in use, is filled with water, and effectually prevents the escape of any of the products of combustion. It is desirable to tin, as it is technically called, that part of the pipe against which the water rests, as it will prevent oxidation. A flue-pipe, *b*, 1½ inch in diameter, proceeds from the stove and contains a throttle, *c*—that is, a flat circular piece of metal, of the same diameter as the inside of the flue, turning upon a pivot, so that, when its transverse diameter is in the same direction as the length of the pipe it does not impede the escaping gas, but when turned across the pipe it closes it. The chimney of my stove is of zinc, and travels from the centre of the end to the opposite extremity of the side of my house, and descends gradually during its whole course.



a, Gutter. *b*, Chimney.
c, Throttle valve. *d*, Handle.

I will now endeavour to explain the philosophy of the arrangements I have pointed out. The fuel chosen is charcoal broken small. Charcoal may be obtained of the requisite size for this stove at a lower price than in larger lumps. The charcoal in burning is converted into carbonic acid and ash. The ash, being that part of the wood from which the charcoal was made, which the tree took up from the earth, is a most valuable manure, and adds wonderfully to the power of potting soil. This ash falls to the bottom of the stove, and so leaves free the holes by which air is supplied. The carbonic acid formed by the union of the oxygen of the air with the carbon of the charcoal is about one and a half of the specific gravity of the atmosphere, and so when cold it falls; but as it is produced in the stove at a high temperature, it is expanded and rises. As it passes into the chimney it cools, and, becoming heavier than the air, tends to descend; for this reason the chimney is made to slant downwards. It thus assists the draught, and acts also as a damper; for if the fire should be dull the chimney pours out its heavy well-cooled charge of carbonic acid, and so draws up the fire; but if the fire be burning fiercely the heat is not expended so readily, and the carbonic acid when it has reached the chimney, still tending to rise, has to be forced out by the rising hotter air in the stove, and this checks the combustion.

The object of the throttle has already been hinted at. By its means the fire may be governed as easily as an ordinary gas-burner.

When my stove was finished I lighted and filled it, and turning the throttle very low left it untouched, watching how long it would burn. It continued alight for a hundred hours. The amount of heat given was very small, but my experiment was to ascertain the lowest combustion attainable. In ordinary frosts I light my fire about nine at night, and next morning put on about a quart of charcoal, turn the throttle very low, and about seven in the evening pour the contents of the stove into a fine round garden sieve. I riddle the lighted contents, and so get rid of the dust, pour back, and refill; and I repeat this day by day with what variations the weather may necessitate. The fire has never once gone out without my intending it during two winters, nor have my plants suffered from frost all through this severe weather owing to the stove failing, although I have had no mats on the roof, and my greenhouse is 100 feet at least from any building, so that it is very much exposed.

There are other points which might need explanation, such as the method of lighting, the reason why plate iron will not answer for the chamber supplying air, cost of fire, &c.; but as I must be trespassing on your space I will leave these matters, promising to take them up should any of your readers need information respecting them.—F. Cheshire, A.C.P.

DECISIONS OF THE FRUIT COMMITTEE OF THE ROYAL HORTICULTURAL SOCIETY.

We are much surprised at reading the report of the Committee's judgment upon the Main Crop Potato at the last meeting, and we would like to ask under what conditions the Potatoes are placed before the Committee, as all the varieties of this important vegetable lately submitted for their inspection appear to receive uniform condemnation. The system of boiling at a place where cooking is not carried on to any extent appears to us to be objectionable, and we think the Fruit Committee should lay down some specific course of action.

We recommend, as the fairest way, that a notice be given, "that no Potato will be judged until it has been grown in the Chiswick trial grounds." Under the present conditions even this trial is no safety, because our Main Crop Potato, which is really a first-class variety, was grown at the Chiswick trial grounds in 1868, and we have reason to believe was then considered to be one of the best, if not the best, of the red-skinned class. We should like to ask Mr. Barron, the garden superintendent, who grew it, to write his opinion of it as grown and tested by him at Chiswick. We fail to see how a Potato can change its character in two years, and we know that when tested on Wednesday, the 18th, the dish of Potatoes had such an appearance when served up, that no gentleman would permit them to be placed on his table. We are strongly of opinion that a bad variety cannot be too soon condemned. We are also equally sure that all varieties should have a fair and proper trial. Having this in view, we should like to ask why the report of the Chiswick trial has never been made public?—James Carter & Co.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Lose no opportunity of bringing the ground into a good working condition for the crops which must soon be committed to it. A generous soil always pays well for the extra labour of frequently turning it. *Asparagus*, a fresh bed should now be planted; a very considerable proportion of leaves should be used in the formation of the bed. The beds in cutting should have air freely admitted during mild weather. A crop of *Beans* should be planted in boxes or pots, which should afterwards be placed in a forcing house. At the same time a crop should be planted in the open ground where it is in good condition. Make a sowing of Early Horn *Carrot* on a slight hotbed, to come in for a first crop. Where the soil is light and dry, a sowing may be made on a south border. Those who are short of old *Onions*, or who wish to grow some of a large size, should now sow some White Spanish in a box, which should be placed in a forcing house. The Underground sort may now be planted.

Sow *Peas* in pots or boxes for planting out in March, also two crops in the open garden, one of an early variety, the other of an approved kind which does not come in so quickly. Sow another crop of *Radishes* in a frame where there is a little bottom heat, or they may be sown where Potatoes are planted. A crop should also now be sown on a south border. Keep up a succession of *Sea-kale* and *Rhubarb* either by covering the roots with pots and fermenting material, or by planting them in pots and placing them under stages in the greenhouse or stove. The latter method has the advantage of giving much less trouble than the former, a great consideration in the busy time which is approaching.

FRUIT GARDEN.

Planting in every part, both against walls and in the open quarters, should be completed without delay. Mulch the newly-planted trees, and at once stake those requiring support. Prune and nail Apricots, and continue the same with other wall trees not yet completed. The following composition is recommended as a dressing for Peach and Nectarine trees—viz., Scotch snuff, fresh slaked lime, sulphur vivum, of each 1 lb.; mix with soap-suds to the consistency of paint, add sufficient soot to make the whole of a grey colour, and lay it on with small paint brushes. I suspect this composition has a more important influence than the destruction of insects or their eggs, as the leaves of the trees to which it is applied are generally of a more healthy appearance throughout the summer than those left without dressing. Where Filberts are brought under the dominion of the knife and spade—by far the best method of cultivating them—let all suckers be effectually removed, and some manure forked in about the trees. Shorten all the strong shoots of last year's growth, but do not interfere with the small ones, as it is from these the nuts are principally produced. It is better to thin out the large branches if they are crowded with wood.

FLOWER GARDEN.

Proceed as rapidly as the weather will permit with the removal and planting of large shrubs. Layering may be successfully performed where the plants have become bare and unsightly at the bottom. Fork over the borders in the shrubbery, sweep and roll the grass edgings and walks, remove everything unsightly, and let the whole assume an air of neatness and order. Those who are much annoyed with worms may try the following receipt—Take 1 oz. of corrosive sublimate, grind it fine, and dissolve it in sixteen gallons of water; then with a watering-can and fine rose water the turf infested. This will bring all the worms in a great hurry to the surface, when they may be picked up in a watering-can and carried to a distance. Anemones and Ranunculuses may be planted if the ground is in a dry state, and the weather mild. If the soil of the bed be in a poor condition, throw it out to the depth of 1 foot, place a layer 6 inches thick of well-rotted hotbed and cow dung, and fill up the bed with fresh maiden loam from a pasture. Before planting, lay the roots between the folds of a wet piece of flannel for twenty-four hours. Carnations and Pinks in pots should be attended to; remove all damp, and protect them from heavy rains. Keep Auriculas and Polyanthuses tolerably dry at this season. Prepare a rich compost for top-dressing by frequent turnings. Hyacinths may still be planted; to have them in perfection apply plenty of rotten cow dung to the beds. Those beds which were planted in autumn should be stirred on the surface with a fork, and top-dressed with the same material. Prepare beds for Pinks, Carnations, and Pansies. Look over the Dahlias, and remove all decayed portions from the stems and roots.

GREENHOUSE AND CONSERVATORY.

Now that the shortest day is past some of the plants which it is intended to make the most of during the growing season may be started gently preparatory to being potted about the middle of next month. Any nice compact plants of the finer varieties of Scarlet Geraniums which are intended to make specimen plants for vases, baskets, or single specimens on the lawn during summer should now be shaken out of their pots, and repotted in fresh soil. Give them, if possible, a gentle bottom heat for a week or two until they make fresh roots, and keep a moderately moist atmosphere, with a temperature of from 45° to 50°. After they have fully recovered the check remove them to a light airy part of the greenhouse, and place them in large pots or tubs towards the end of March, where they will produce trusses of splendid bloom from June until September or October. Herbaceous Calceolarias from this time forward should be grown rapidly, potted in similar compost to the Geraniums, and kept in a moderately moist, close atmosphere of from 45° to 55°; draw a syringeful of clean tepid water over them about one o'clock on clear sunny days, and remember that the green fly will quickly devastate your Calceolarias if you do not fumigate with tobacco about once a-fortnight. Cinerarias, if they happen to be underpotted, or have been standing near the heating apparatus during the late severe weather, must be sharply looked after, or they will soon become smothered with insects. Fumigate them in time, and assist those which are coming into bloom with a little clear liquid manure once a-week. Fuchsias must also be looked to without delay, where fine specimen plants are required. Shake the old plants out, reduce the roots, and repot them, introduce them to a forcing house at a temperature of about 60°, and as soon as you can take cuttings an inch long, strike them, and grow them as quickly as possible, remembering that if you want large plants they must be grown to a considerable size before they show bloom. For soil use light, turfy, sandy loam, such as the edgings of gravel walks, with turfy peat, half-decomposed leaf mould, a little charcoal, and some sand.

STOVE.

Some of the plants will now begin to grow, such should be potted if they require it, and be placed in the warmest and lightest part of the house. Seeds of stove exotics may now be sown; some will require to be placed in a hotbed, particularly the seeds of many of the Leguminosæ, while others will do better in a stove where there is a greater amount of air and less heat.

PITS AND FRAMES.

Give plenty of light and air to these structures in fine weather. Inspect the plants at every opportunity, and pick off all damp and decaying leaves. Fumigate with tobacco if the plants be infested with green fly; this ought to be attended to prior to taking off cuttings, as this insect soon increases in number when brought into a higher temperature. Pot off autumn-struck cuttings of Scarlet and Ivy-leaved Geraniums, Fuchsias, Verbenas, shrubby Calceolarias, &c., that are still in the cutting pans; place them in a little heat till they are well rooted. Make a hotbed for cuttings and seeds with fermented dung well sweetened. Those who do not possess great advantages, and yet are expected to have the flower garden very gay in the summer and autumn, may do much with a small supply of fermenting material by making a hotbed 3 feet high at the back, 2 feet high in front, and the size of a single-light box.—W. Keane.

DOINGS OF THE LAST WEEK.

Up to this, the 21st instant, we have had a trying week for gardening. What with dense fogs and mists, heavy rains, boisterous winds, snow, sleet, thaw, and frost, fitfully and almost hourly succeeding each other, we hardly knew what to do as respects all out-door gardening. No better proof than we have had of late could be given of the advantage of a small house of glass over a pit or frame, as with the latter little could be done in such weather. A house, with means of *heating* it, is also a great improvement over a house not heated at all, or heated imperfectly; for nothing is a greater damper to enthusiasm in gardening than to see plants perishing from cold, and be destitute of the means of preventing it. For all small houses, heating by a brick or iron stove inside the house will ever be the most economical plan, and a little care will prevent dust from ashes. The firing, &c., can all be done under cover. The next cheapest mode is having a little flue either beneath the floor-level, the top of the flue forming part of the tiled pathway, or the flue may be placed above the floor, where it will be least conspicuous. We prefer the former, as the flue is not seen. Hot water will always be found the best where there is much heating to be done. Where the place is very small, heating by gas, with or without a little boiler, is very handy, and so is heating from a kitchen boiler, when the position suits, and it will only suit when all the heating pipes are above the level of the boiler.

The work as a whole was very much a repetition of what we have alluded to in previous weeks' notices, and, therefore, without any particular arrangement as to departments, we shall allude to a few matters that have come more prominently before us.

Window Gardening.—When Geraniums and other plants have been kept in warm rooms, they are apt to be lanky and sickly after such a winter, and may want a little nipping back, but as this done now would be apt to retard blooming, it is better to avoid it, if the plants are at all stubby. We have received many complaints from those who grow in pots and

boxes Scarlet Geraniums, which they either cut down in the boxes in which they grew, or cut down, took up out of the ground, and packed firmly like faggots. The complaint is, that from covering up in a dry room in the hardest frost, the plants seem alive, but make no growth. All the better for them if they do not for a month or more. If such plants make some leaves the size of a sixpence by the middle of March, they will be quite early enough for blooming in a balcony or garden in June.

The great enemy to window plants grown inside of our rooms in winter is the dust, which will collect on the foliage, and soon makes the plants sickly and woebegone. The great cure is frequent sponging and washing the leaves. The plants look very different after such a bath. The water used should be fully as warm as the room, say from 60° to 65°. If used warmer, it is apt to make them tender. A very quick way of doing this washing, in the case of moderate-sized plants, say in 5 or 6-inch pots, is to have a pail of the warmed water, place a piece of cloth firmly over the surface of the pot to prevent soil falling out or the water wetting it too much, reverse the plant, and pull the head gently through the water, so as to wet every leaf and bit of stem. Then use a sponge, or draw your fingers softly through and along the leaves, so as not to injure them, and then swinge the head again in a pail of clean water. At this season excess of watering is to be avoided. If the room is hot and dry a sprinkling over the top will often be more beneficial than saturating the roots. In no case, except, perhaps, that of a strong vigorous flowering bulb, should any water be left, except for a minute, in the saucers. Pricking up the surface of the soil, and adding a little fresh, will much improve the appearance of the plants, and they will also rejoice in clean pots. A dirty slimy pot is a disgrace to a window, and a plant will not thrive in it so well as in a clean pot. All such pots are apt to be tell-tales in more ways than one.

When we advise very careful watering we do not wish that the soil should be allowed to be dust-dry. When it is necessary to water, give enough to moisten all the soil containing roots, and then wait patiently until your services are required. Do not be afraid to turn a ball out now and then, or put your finger down into a pot, so as to render yourselves sure as to its condition. Without such trouble perhaps you may gain the knowledge wanted just by ringing the pot with your knuckles. If it emits a dull heavy sound you may keep away the watering pot. If it emits a clear sound like a clean whole vessel of earthenware, you may be sure the soil is dry.

There is hardly, however, any rule without exceptions. Thus some of our window gardeners have taken to Cinerarias and Calceolarias in winter and spring. Both like moisture, and they will thrive all the better from standing on a cool bottom, such as a little moss kept moist in the bottom of the saucer. Such treatment would ruin the Cactus tribe, which we are glad to find are becoming favourites with many window gardeners, owing to the splendid colour of the blooms in summer. If the room is not very warm, they will need little or no water in winter, unless the succulent stems show signs of shrinking. Damping the stems will often be better than watering the roots until the days become longer and yield more sunlight. Fuchsias kept in cellars or spare rooms, if now beginning to break, showing little leaves, should be brought to the light, and ere long be repotted in the same-sized clean pots, getting rid of a good portion of the old soil. The more growing plants are exposed to the full light the better, and much may be done in a window by frequently turning and moving, so that all may obtain a due share of light. The safest place for all such favourites in severe frost is the middle of the living room at bedtime, and even then in very severe weather a clean cloth thrown over them will be a great means of protecting them, and keeping them clean.

In alluding to old *Scarlet Geraniums* either saved in the boxes in which they grew, or taken up and packed, the great point after all the leaves have been removed late in autumn, is to keep them over the winter, and give no encouragement to growth until the spring. Very little water will be required in winter if they are kept in a cool airy place, free from frost, and nothing is better than a little dry hay or short litter shaken over them, and then any spare room will keep them well. If a little water should be necessary to prevent their becoming dust-dry, instead of deluging the pot or box it is better to make a few holes with a pointed stick, and pour the water gently into them, allowing it to percolate gradually through the mass. Were many of our readers thus to treat old Scarlet Geraniums, they might have the same plants on their balconies year after year, for a score of years, by merely picking away the surface soil in spring, and adding rich compost. The succulence stored up in the old shoots acts as a reservoir of supply, just like a tuber or a bulb. It is very different with all young plants raised from cuttings in summer and autumn. These must have light and air, and be kept slowly growing all the winter. The old-established plants are, therefore, the best for the millions of window gardeners who have no house or pit to help them.

Raised Banks in the Kitchen Garden.—Besides what was lately alluded to, we have met with instances of the advantage in such severe weather of dry and even northerly exposures. For instance, on a bank on a north aspect young Coleworts have stood untouched by the frost, whilst those on a southern exposure and on the level have somewhat suffered. Lettuces sown and planted out at the foot of walls, &c., with east, west, and south exposures, have suffered severely, though protected with laurel boughs and a little litter, whilst plants on broad ridges having a row along the centre and three or four rows on each side, have as yet stood uninjured. The greater dryness no doubt helped them.

We have been collecting material for hotbeds, some to be rather permanent, and others for temporary purposes. As stated in previous years, we make the most of stable manure, not working it too much before using it, and covering with a layer of sweet warm tree leaves. We have some excellent dung at present, pretty well made to our hand. In the severe frost it was not safe to take the horses out for exercise, and a ride was made in the stable yard by spreading the dung there day after day. It has thus been well cut up and mingled by the horses' feet, and after lying a few days will be in fine condition for Cucumber beds, and even first-rate, after one or two turnings, for Mushroom beds.

Prepared beds for *early Potatoes*, Horn Carrots, Radishes, Lettuces, &c., as referred to last week. We think we gather Ashleaved Potatoes earlier when we have them several inches in height in small pots, and the pots filled with roots before planting them in a bed. There is no better plan of securing early Potatoes than growing them singly in 6 or 8-inch pots, earthing the pots over as the plants grow, but letting the tubers come on in the pot. They in general come considerably earlier than when planted out in a bed, and where the roots have more free space to run in.

Radishes protected in an earth-pit are still pretty good, but are not so crisp as younger ones raised on a little heat. We generally grow a good many in an early Carrot bed, the seed being sown broadcast, and in various ways; but we think we obtain the largest supply of Radishes and Carrots, and the one interfering but little with the other, by sowing the Carrots in rows 7 or 8 inches asunder, and the Radishes in rows between. The Radishes will be gone by the time the Carrots want all the room. There is nothing that can yield better than a small bed of the Dutch or Early Horn Carrots, and they are very sweet when assisted with a little heat. Instead of thinning so much, we prefer thinning as we pull for use.

Coolness for Calceolarias.—We have alluded to the importance of a small heated house for an amateur, over a pit or a frame. Perhaps there is just one thing where artificial heat would not be of much advantage, and that is in the case of our bedding Calceolarias. We feel sure that bad results in the summer and autumn are often owing to the coddling the plants receive in heated places in winter. We think they do better when, from taking the cuttings in October up to planting-out time, they never in any way receive fire heat; not but that they will thrive very well in a house that is a little heated, but they ought to be as cool and airy as possible, and must be kept much moister than would suit Geraniums of any section. Ours seem all right as yet in a cold pit, though it was covered up more than a fortnight, but they were too cool to grow much.

Verbenas.—It is only fair that failures and misfortunes should be chronicled as well as successes. Generally we have had no trouble with Verbenas, striking them thickly in pots in autumn, keeping them in these pots all the winter, and cutting the tops off for spring propagation, as we generally preferred spring-propagated plants for free growth and free flowering. Last autumn we used fresh sandy loam, and other modes the same as usual, and the plants struck well and looked well until the winter fairly set in, and then they began to show brown and black blotches at the points, and then the same discoloration proceeded farther down until the plants almost died outright. A number of years ago we prided ourselves on having a good collection of bedding Calceolarias, but the most tender of them began to be affected in much the same way, and many

varieties we had to give up. We failed to find out the cause of the disease. If we have had nothing of the sort amongst the Calceolarias of late years, there is no credit whatever due to us; for, just as with the Cucumber disease, we are quite ignorant of what caused it or what enabled us to get rid of it. We are equally ignorant of the cause of this attack on the Verbenas, though from the great dryness of the summer, and an inability to give water for months, we had an unusual difficulty in securing cuttings. Have others had their plants assailed in a similar way? or could they assign a reason for this gradual withering up? We may add that they were not affected by frost, and were kept much the same as we have treated them successfully in other years.—R. F.

TRADE CATALOGUES RECEIVED.

E. P. Dixon, 57, Queen Street, Hull.—*Catalogue of Seeds for the Farm and Garden.*

D. Gold McKay, Market Hill, Sudbury, Suffolk.—*Illustrated and Descriptive Spring Catalogue of Flower, Kitchen Garden, and Agricultural Seeds.*

Smith & Simons, 36 and 38, Howard Street, St. Enoch Square, Glasgow.—*Cultural Guide and Descriptive Seed Catalogue.*

C. H. Dickson, 23, Market Place, Manchester.—*Catalogue of Vegetable and Flower Seeds.*

Peter Lawson & Son, 20, Budge Row, Cannon Street, London, E.C., and George IV. Bridge, Edinburgh.—*Catalogue of Garden Seeds, Bulbs, &c.*

Edward Taylor, Malton. — *Catalogue of Agricultural, Kitchen Garden, and Flower Seeds, &c.*

R. Dean, 8, Denmark Villas, Ealing, London, W.—*Descriptive Catalogue of Vegetable, Farm, and Flower Seeds.*

James Vick, Rochester, New York.—*Illustrated Catalogue and Floral Guide.*

TO CORRESPONDENTS.

Salt or Saltpetre for Mushroom Beds (*A. Y. Z.*).—Such saline manures are very injurious to all fungi. A little salt put upon a Mushroom reduces it to a black liquid and pulp.

Roses (*A. B.*).—The first you name we think must be Hybrid Perpetual Enfant du Mont Carmel, the second Reine d'Angleterre (Gallica), and the third Duchesse de Cambacérès (H. P.). The reason you could not find them is, they have been superseded by better varieties.

Hays' Stove.—"*K.*" wishes to know if any of our readers has one of these stoves to dispose of. If so, let them communicate with the publisher of this Journal.

Musa Cavendishii after Fruiting (*J. C.*).—After fruiting, the plants are of no value except for affording suckers. Immediately the fruit is cut take the plants out of the old tubs or pots, partly disrnot, pot, and plunge them in a bottom heat of 85°. Suckers will be produced readily, and should be transferred to small pots, and shifted into larger pots as required.

Alocasia metallica and macrorhiza Culture (*Idem*).—Pot them now or early next month, or just when they are beginning to grow, using for the former a compost of two parts fibrous brown peat, one part old dry cow dung, one part light fibrous loam, and one part charcoal in lumps between the size of peas and hazel nuts, the whole being torn in pieces with the hand, and not very finely, using the compost rather rough. Add one part of silver sand, mixing the whole well together. For A. macrorhiza employ the same ingredients, but let the compost be finer than for A. metallica. After potting place the plants in a house with a brisk moist heat, and if the pots could be plunged in a bottom heat of 80° to 85° all the better. The top heat should range from 60° to 65° at night, and 70° to 75° by day until March, when the temperature may advantageously be raised to 65° or 70° at night, and 75° to 85° or 90° by day, admitting air moderately, and maintaining a moist atmosphere. Shade will be necessary from very powerful sun.

Blue Gown Cucumber (*H N.*).—It has been awarded three first-class certificates, and is described as "a superior black spine, growing to a length of 26 to 30 inches, of uniform size, and having a fine bloom." Our correspondent also wishes to know where "Tindall's No. 2" Cucumber seed may be obtained.

Mulberry Propagation (*E. M.*).—Cuttings may be put in either in spring or autumn. You may put them in from now until March. Take the well-ripened shoots of the previous year, giving the preference to those from the upper part of the tree, and each cutting must have a joint of the two-year-old wood at its base. Insert the cuttings in light, sandy soil in a shady place, leaving two or at most three eyes above ground. All they need is weeding, watering in dry weather, and protecting from frost in winter, strewing some dry litter over them in severe weather, and removing it in mild periods. You wish to put in a branch; cut it off immediately below a fork or joint, and trimming off the shoots to a height of 18 inches from the base, insert it in the ground in light soil in a warm border, but shaded, and a foot to 15 inches deep. Make firm with a stake, and water in dry weather. The age of the branch is immaterial, only it should have some portion of wood more than a year old.

Pruning Laurels (*J. R. W.*).—The mode of pruning pursued by your gardener is good, and we have no suggestions to offer, only as you object to the appearance of the shrubs for a time after pruning, they must have been cut back very much, so as to remove all or nearly all their foliage. We should cut them back in March, or when they are beginning to grow, and go over them again in July or August, and remove any irregularities of growth. This for the common Laurel, but the Portugal Laurel we would only prune every alternate year, and instead of close pruning every year, we would every alternate season merely remove any irregularities of growth. When hard cut every year they become weak and stunted in growth.

Planting Under Large Chestnut Trees (*M. D.*).—As turf will not grow we know of nothing that would serve you so well as Ivy. We advise Rægner's Ivy, which has large distinct dark green foliage. Periwinklee would also answer, and are very pretty, Vinca elegantissima being especially fine.

Plants for Greenhouse (*Amateur*).—Your house will be suitable for the following, but having a temperature of 65° it is not a greenhouse, but a stove; 45° is the highest temperature from fire heat any greenhouse plant requires:—Acacia armata, A. oleifolia elegans, A. pulchella, Acrophyllum venosum, Beaufortia splendens, Aphelexie macrantha purpurea, Boronia Drummondi, Chorozema cordatum splendens, Citrus japonica, Correa Brilliant, Cyclamen persicum vars., Cytisus racemosus, Eutaxia floribunda, Hydrangea japonica variegata, Kalosanthes miniata grandiflora, Myrtus communis, Nerium rubrum plenum, Rhododendron jasminiflorum, Statice brassicæfolia, and Vallota purpurea. Azaleas: Brilliant, Criterion, Mars, Queen Victoria, Stella, and Duc de Nassau. Camellias: Fimbriata, La Pace, Madame Pepin, Monarch, Valtevaredo, and Alexina. You can add Fuchsias, Pelargoniums, Cinerarias, Calceolarias, and Primulas, which are effective in their season. The back wall we would cover with Camellias, or Habrothamnus elegans and Luculia gratissima, all winter-flowering. If the back wall be shaded by plants in front, no flowering plant would thrive on it.

Gesnera Treatment (*M. A.*).—Your plants being those of G. exoniensis, you have failed from their requiring a stove temperature. They will not succeed well in a greenhouse, or only for a short time when in flower. Your only plan will be to keep them in a light and warm position in your greenhouse, giving no water beyond enough to keep the foliage fresh or from flagging, and gradually dry them off. In July repot, and place them in a hotbed, growing there as long as you can, and before cold weather sets in remove them to the greenhouse, but we fear they will not flower unless you can give them a temperature of 55° at night. We grow our plants in a late vinery, and transfer them to the stove for flowering. They have been in good bloom the past six weeks, and we shall now dry them off.

Anonymous Correspondence (*Quæstor*).—The observations were directed generally to check unworthy conduct. Your observations are altogether personal, and written to annoy without the possibility of being beneficial.

Hot-water Piping (*A Subscriber*).—If you did not object to the first expense, you would need from three to four 4-inch pipes all round the house.

Advertising (*S. E. F.*).—Your advertisements will be 3s. each.

Applying Sulphur (*Lupus*).—Using a pair of bellows is the common mode, well known to gardeners.

Roses (*W. H. B.*).—The varieties you name would do very well at Upper Norwood.

Cucumber (*Thomas Eads*).—We do not know where Dale's Conqueror Cucumber is to be had. Seedsmen who possess it ought to advertise it.

Fruit Trees in Orchard House (*A Subscriber*).—For such a lean-to house, and where the plants are to be allowed to grow some size, we would, as there are trees against the back wall, have two rows of Peaches and Nectarines in front, and say at 4 feet apart, or eight in the row. These might be of Peaches—one Acton Scott, one Grosse Mignonne, one Noblesse, one Royal George, one Violette Hâtive, one Barrington, one Walburton Admirable, one Tèton de Venus. Of Nectarines—two Elruge, two Violette Hâtive, two Rivers's Orange, one Downton, one Roman. By having small plants you could have twenty-four plants instead of sixteen, and some put them as close together as 2 feet apart, but we do not think anything is gained by crowding. In such a house with pipes round it, Vines in pots will do very well until those on the roof come in. With Peaches on the wall, and the pyramids and standards in front, we would not plant Vines so closely as 4 feet apart. If you do, as they fill the house, the trees shaded by them will do little good; from 6 to 8 feet apart would be better. You cannot beat Black Hamburgh for such a house, and Royal Muscadine and Buckland Sweetwater as Whites. If you want to have them late, then Raisin de Calabre and Lady Downe's. With late Grapes, however, you cannot use the house much until they are cut. Six feet will do for a Vine border if you cannot have more, but we would have the border inside and outside too if you could manage it, and plant inside.

POULTRY, BEE, AND PIGEON CHRONICLE.

FRENCH FOWLS.

In your report on the Bristol Show, I see you remark that not a single La Flèche cock was exhibited in the French class. I have been for some time a fancier and breeder of this description of fowl, and have taken many prizes, and I must say I would never think of sending my fowls to any show where the French breeds are all classed together, knowing well that my fowls would stand a bad chance of winning when competing with breeds of a larger description, such as Crêve-Cœurs and Houdans. The entries in the French classes at the above Show were very large, and were worthy of separate classification. Generally speaking, the committees of poultry shows do not give the breeders of French fowls much encouragement. —George Alex. Stephens, *Dublin.*

Light Brahmas.—The Torquay Show bids fair to become as distinguished this year as last, and I hope it may be so in every class. To insure a collection of Light Brahmas, such as has not been hitherto seen west of Bristol, I hope to get up a good cup for the best pen of this handsome variety, one which has perhaps

been established more by the perseverance of a few admirers in offering cups than any other. Mr. Pares has kindly offered his assistance, and I now appeal to every admirer in the fancy to give me his support, and also to send specimens to the Show.—JAMES LONG, *Princess Square, Plymouth.*

OUTRAGE ON A PRIZE BIRD.

HAVING had a most mischievous outrage—and I regret to hear by no means an uncommon one—perpetrated on a valuable bird on its way from the Bristol Show, I venture to suggest a remedy which might be practicable if secretaries would only be willing to lend their aid towards it. My Silver-Grey Dorking cock, which had just taken the first prize at Bristol as at various other places, has been on his way home entirely stripped of sickle feathers, as well as of some of the other side tail feathers, one of the great ornaments of this breed, as every connoisseur well knows. A handsome bird is thus for a year made useless for showing as well as unhappy to look at, and is also weakened. Such outrages are made possible by the way in which baskets are fastened at shows, with little bits of wire, easily untwisted and twisted up again at any station. I beg to suggest that exhibitors of specially valuable birds should keep a padlock for each basket, with two keys, one of which should beforehand be sent by post to the secretary, and he or his deputy alone use it, and after the show return it to the owner.—O. E. CRESSWELL.

KENDAL POULTRY SHOW.

THIS was held in Albert Buildings, on the 19th, 20th, and 21st inst, and in all respects was much superior to any of its predecessors. The number of entries in the Poultry department was 658. The success of the Show this year must be a great satisfaction, both to the Committee and the excellent Hon. Secretary, who did all in their power to add to the comfort both of the visitors and the very valuable stock placed under their care. The great number of cups and other articles of plate offered by private gentlemen, and some by the Committee, no doubt caused the large increase in the entries. Mr. Hewitt, who was to have been one of the Judges, was prevented by indisposition, and the awards were made by Mr. Teebay, of Fulwood, Preston, and Mr. Dixon, of Bradford.

The *Game* classes were of very great merit, in fact we never saw a better lot brought together. The five classes contained fifty-four pens, most of the principal Game exhibitors in the country competed, and a great many first-class birds had only a high commendation. Of the *Hamburghs* there were not large entries, but nearly all the pens were everything that could be desired. Mr. Belden took the cup with a beautiful, and we think we may say a perfect pen of Gold-spangles. The adult *Dorking* class numbered sixteen pens, the chickens twelve pens, and Silver-Greys ten pens. The cup for the best pen went to the chickens of Messrs. Gunson & Jefferson, of Whitehaven. The *Cochin* classes were all of very high quality, and the entries were large in all the classes. The cup went to Mr. Taylor, of Mauchester, but the best class in the Show was that for the Whites. We never saw so many first-class birds of such faultless purity brought together before. Mr. Sichel's first-prize pen was a treat to look upon, and Mr. Smalley's was scarcely inferior; both these gentlemen may be proud of their birds. Many of the *Spanish* were of great merit, Mr. Brierley taking the cup with a wonderful pen. The *Brahmas* were mostly good, and the entry large. The Selling Class contained seventy-three entries, nearly all breeds being represented, and all were to be sold by auction during the Show. The entries in the Bantam classes were large, and all the classes were really good. The cup for a single Game cock was won by Mr. Julian, of Hull, in a splendid class of seventeen. The cup for Ducks was won by Mr. Stott, of Rochdale, with Rouens in a class of twenty-one. The East Indian Ducks were capital in plumage, and an entry of seventeen is something to be proud of. Mr. Burn took both first and second prizes. All the *Pigeon* classes contained some capital pens; most of the local classes were very good, and several pieces of plate and cups were awarded in them.

GAME.—*White and Piles.*—1, T. Mason, Lancaster. 2, C. W. Brierley, Middleton. 3, J. Stabler, Driffield. *hc*, R. Knight, Gilthwaiterigg; J. Brough, Carlisle; H. C. & W. J. Mason, Drighlington. *c*, H. Thompson, Penrith. *Black-breasted and other Reds.*—1 and Cup, C. W. Brierley. 2, T. Mason. 3, H. M. Julian, Hull. *hc*, J. W. Will, Errol; E. Ackroyd, Ecclesbill; J. Barrow, jun., Bradley Field, Kendal. *Chickens.*—1, J. Mashiter, Ulverston. 2, J. W. Will. 3, H. M. Julian. *hc*, E. Ackroyd. *Any other Variety.*—1 and 3, H. M. Julian. 2, —Woodhouse, Ulverston. *hc*, H. Jowett, Idle; J. Mashiter; W. J. Cope, Barnsley. *c*, H. Jowitt; C. W. Brierley. *Hen.*—1, C. W. Brierley. 2, J. Barrow, jun. 3, F. Sales, Crowle. *hc*, T. West, St. Helens; T. Mason; T. Kew, Burton, Westmoreland. *c*, Mrs. A. Dawson, Kendal.

HAMBURGHS.—*Silver-spangled.*—1 and 2, D. Lord, Stacksteads. 3, H. Beldon Goitstock. *hc*, Ashton & Booth, Mottram. *Golden-spangled.*—1 and Cup, H. Beldon. 2, H. Pickles, jun. 3, J. Ogden, Hollinwood. *hc*, J. Newton, Silsden. *Silver-pencilled.*—1, H. Pickles, jun. 2, W. M. Mann, Kendal. 3, H. Beldon. *hc*, H. Smith, Keighley; J. Robinson, Garstang; H. Pickles, jun. *Golden pencilled.*—1, H. Beldon. 2, C. Moore, Poulton-le-Fylde. 3, J. W. Will. *hc*, H. Pickles, jun.

DORKINGS.—*Coloured, except Silver-Grey.*—1, D. Gellatly, Meigle. 2, Mrs. Arkwright, Sutton Scarsdale, Chesterfield. 3, J. Robinson. *hc*, S. H. Stott, Roehdale; R. D. Holt, Windermere; J. Copple, Preacot (2). *Chickens.*—1, Gunson & Jefferson. 2, Miss Fairhurst, Ormskirk. 3, W. W. Ruttlidge, Storthead. *hc*, W. H. King, Roehdale; S. H. Stott; Mrs. Arkwright; J. White, Warlaby. *Silver-Grey or any other variety.*—1, R. Smalley, Lancaster. 2, W. Jackson, Bolton-le-Sands. 3, J. Robinson. *hc*, R. D. Holt.

COCHIN-CHINA.—*Cinnamon and Buff.*—1 and Cup, W. A. Taylor, Manchester. 2, G. H. Proctor, Durham. 3, J. Sichel, Timperley. *hc*, Gunson & Jefferson; J. Watts, King's Heath, Birmingham. *c*, R. Hine, Bedlington; W. Marsland-Milverton; J. Hine, Kendal. *Brown and Partridge-feathered.*—1, E. Tadman, Whitchurch. 2, J. White, Whitley, Netherton. 3, T. Sharp, Ackworth. *hc*, W. A. Taylor (2). *White.*—1, J. Sichel. 2 and 3, R. Smalley. *hc*, R. Smalley; E. Fearon; J Sichel; J. Stephens, Walsall. *c*, H. Yardley; A. D. Cochrane, Stourbridge.

SPANISH (Black).—1, C. W. Brierley. 2, H. Beldon. 3, H. Wilkinson, Earby. *hc*, G. C. Wilson, Milnthorpe; Hon. Miss D. Pennant, Penrhyn Castle, Bangor. (2). *c*, H. Yardley; H. Monson, Bishop Auckland.

BRAHMA POOTRAS.—1, J. H. Dawes, Birmingham. 2, Mrs. Arkwright. 3, J. Sichel. *hc*, J. W. Brockbank, Kirksanton; W. Masland; E. Leech, Rochdale; Hon. Miss D. Pennant; J. Mashiter; J. Watts. *c*, Mrs. W. F. Wharton, Birmingham.

ANY OTHER VARIETY, EXCEPT BANTAMS.—1, H. Beldon. 2, W. A. Taylor (Cuckoo Cochins). 3, R. Smalley (Crève-Cœurs). *hc*, Mrs. W. F. Wharton (Houdan); J. Robinson; J. Watts.

SELLING CLASS.—1, R. Smalley (White Cochin). 2, J. W. Fawcett, Old Hutton (Rouens). 3, H. Wilkinson, Earby (Black Spanish). *hc*, W. Bentley, Scholes-in-Cleckheaton; W. M. Mann (Silver-pencilled Hamburghs); H. Yardley; H. Lickbarrow, Kendal; G. Fawcett, Lyth; S. Cox, Stacksteads (Rouens); T. J. Harrison, Kendal (Black Spanish); T. Whittaker, Melton Mowbray (Pile Game); E. Fearon; J. Swinbank, Crook (Black East Indian Ducks); J. Robinson; J. J. Waller, Kendal (Dorkings); H. Pickles (Polands); J. Watts. *c*, Miss C. E. Palmer (Golden-spangled Hamburgh); Gunson & Jefferson.

SINGLE GAME COCKS.—1 and Cup, H. M. Julian. 2, C. W. Brierley. 3, J. Bowness, Newchurch. *hc*, J. W. Will; M. Redhead, Kendal; W. H. Stagg, Netherayon; J. Brough. *c*, T. Mason. *Cockerel.*—1, J. Mashiter. 2, T. Whittaker. 3, J. D. Oates, Halifax. *hc*, H. M. Julian; W. H. Stagg.

GAME BANTAMS.—*Cock.*—1, S. W. Smith, Thrapstone. 2, T. Sharples, Rawtenstall. 3, J. Blamires, Great Horton. *hc*, G. Hall, Kendal; Bellingham and Gill, Burnley; W. Caton, Kirkby Lonsdale; J. R. Robinson, Sunderland; T. C. and E Newbitt; H. Beldon. *c*, W. Rogers, Sunderland. *Black-breasted or other Reds.*—1 and Cup, G. Hall, Kendal. 2, T. C. & E. Newbitt. 3, H. Beldon. *hc*, J. & W. Towerson, Egremont; S. W. Smith. *Any other Variety.*—1, T. Sharples. 2, T. C. & E. Newbitt. 3, J. Stabler. *hc*, H. J. Nicholson, Holborn Hill, Cumberland. *c*, J. Watts.

BANTAMS (Any variety, except Game).—1, M. Leno, Dunstable (Laced). 2, J. Walker, Halifax. 3, H. Beldon. *hc*, H. Yardley; M. Leno (Laced); Mrs. Arkwright (Gold-laced); W. J. Cope; J. Watts (2).

DUCKS.—*White Aylesbury.*—1, E. Leech. 2, J. Robinson. 3, W. Stonehouse, Whitby. *Rouen.*—1 and Cup, S. H. Stott. 2, A. Dickinson, West Croft. 3, R. Parkinson, Ulverston. *hc*, Mrs. Banks, Kendal; J. J. Waller; W. Willison, Kendal; W. Evans, Prescot; E. Leech; J. White; J. Newton. *Black East Indian.*—1 and 2, S. Burn, Whitby. 3, G. S. Sainsbury, Devizes. *hc*, G. Cartmel, Kendal; S. Burn. *Any other Variety.*—1, M. Leno (Mandarin). 2, C. W. Brierley. 3, H. B. Smith. (The whole class highly commended).

PIGEONS.—*Carrier.*—1, H. Beldon. 2, C. E. Stretch, Ormskirk. *hc*, W. Jackson; E. Horner, Harewood (2). *Tumblers* (Almond).—1, H. Yardley. 2, H. Beldon. *hc*, E. Horner. *Any Variety.*—1, F. Moore, Burnley. 2, T. Kew. *Owls.*—1, J. & W. Towerson. 2, H. Beldon. *hc*, A. Jackson, Bolton-le-Moors. *Pouter or Croppers.*—1, E. Horner. 2, T. Kew. *hc*, T. Kew; E. Horner. *Barbs.*—1, W. Jackson. 2, E. Horner. *Fantails.*—1, H. Yardley. 2, E. Horner. *hc*, J. F. Loveridge, Newark (2); J. Walker, Newark; J. W. Edge, Birmingham; H. Beldon. *Turbits.*—1 and 2, R. Thompson, Penrith. *hc*, J. & W. Towerson; E. Horner. *Trumpeters.*—1, E. Horner. 2, H. Beldon. *Jacobins.*—1, J. & W. Towerson. 2, R. Thompson. *hc*, R. Thompson; F. Moore. *Any other Variety.*—1, R. Thompson. 2, W. Jackson (Spangled Porcelains). *hc*, R. Thompson; H. Yardley; W. Bearpark, Aisdersby Steeple; H. Beldon; J. Watts; E. Horner.

LOCAL CLASSES.

GAME (Any variety).—*Chickens.*—1, 2, and *hc*, J. Barrow, jun. 3, Graham and Robinson, Kendal. *Pullet.*—1, A. Walker, Troutbeck. 2, W. Wells, Kendal. 3, Graham & Robinson. *hc*, J. Barrow, jun.

HAMBURGHS (Any variety).—*Chickens.*—1 and Cup and 2, W. M. Mann. 3, T. Stuart, Staveley.

SPANISH (Black).—*Chickens.*—1, 2, and 3, T. J. Harrison, Kendal. *hc*, J. P. Harrison, Kendal.

DORKINGS (Any variety).—*Chickens.*—1, R. D. Holt. 2, W. W. Ruttlidge. 3, Mrs. T. W. L. Hind.

COCHINS (Any variety).—*Chickens.*—1, R. G. Pears, Yanwath. 2, A. Fulton, Sedgwick. 3, G. Hall, Kendal. *hc*, J. Glessall.

BRAHMAS (Any variety).—*Chickens.*—1, A. Walker. 2 and 3, T. W. L. Hind. *hc*, J. Glessall.

BANTAMS (Any variety).—*Chickens.*—1 and 2, G. Hall. 3, J. Smith, Kendal. *hc*, J. Rauthmell, jun., Kendal; W. Caton, Kirkby Lonsdale (2).

DUCKS (Any variety).—*Ducklings.*—1, A. Walker. 2, J. J. Waller, Kendal. 3, R. Willison, Underharrow. *hc*, J. Banks, Kendal; R. S. Willison, Underharrow; A. Stuart.

TURKEYS.—1, T. J. Harrison. 2, C. W. Wilson, High Park, Kendal. 3, T. and G. Airey, Preston Patrick. *hc*, Mrs. Bindloss, Castle Green, Kendal.

GEESE.—1 and 2, R. Rawlinson, Kendal. 3, C. W. Wilson.

ABERDEEN POULTRY AND PIGEON SHOW.

THE Northern Poultry Club held their fifth annual exhibition on the 14th inst., in the Artillery Gymnasium, Aberdeen. There were 369 entries of Poultry, and 250 of Pigeons. The following awards were made:—

GAME.—*Cocks.*—1, A. Dewar, Linton, Cluny. 2, J. M. Campbell, Bonnykelly, New Byth. 3, W. Meldrum, Forfar. *hc*, J. Mollison, Ruthven, Meigle. *c*, J. Wood, Dunecht, Waterton of Echt. *Hen.*—1, J. Mollison. 2, W. Meldrum. 3, J. W. Will, Errol. *Chickens.*—1 and Cup, A. Dewar. 2, C. Jamieson. 3, J. Blair, Blairgone, Dollar. *hc*, W. Tosh, Forfar. *c*, P. Campbell, Oldwhat, New Deer.

SPANISH.—*Cocks.*—1, D. Normand, Kennoway. 2, T. Skinner, Woodside, Aberdeen. 3 and *c*, J. Wood. *Hens.*—1 and 2, A. Shepherd, Meigle. 3, J. Wood. *hc*, H. Yardley, Birmingham. *c*, W. Webster, Middlefield, Woodside. *Chickens.*—1 and Cup, J. Waddell, Airdriehill, Airdria. 2, Miss K. Douglas, Liberton. 3, W. Fraser, Kirkton, Durris. *hc*, W. Webster; A. Gibb, Panmure Fens, Broughty-Ferry; J. Morrison, Moroingside, Edinburgh.

DORKINGS (Silver-Grey).—*Cocks.*—1, Mrs. M'Donald, Forres. 2, Miss Swann, Douglas. 3, A. F. Williamson, Caskieben, Blackburn. *hc*, E. Taylor, Fichnie. *c*, D. Gracie, Stonehaven. *Hens.*—1, T. Raines, Bridge Haugh, Stirling. 2, D. Annan, The Torr, Moonzie, Cupar. 3, G. Black, Mill of Craibstone, Auchmull. *hc*, A. F. Williamson. *c*, Mrs. M'Donald. *Chickens.*—1, J. Waddell. 2, T. Raines, 3, D. Annan. *c*, J. Wood.

DORKINGS (Any other Colour).—*Cocks.*—1, Mrs. A. Bruce, Westhill of Airdrie, Meigle. 2, B. C. Urquhart, Meldrum House. 3, J. Clark, Fochabers. *Hens.*—1, A. Shepherd. 2, Mrs. M'Donald. 3, A. Haggart, Leslie. *hc*, Miss H. R. Lind, Ladieskford, Fraserburgh. *c*, L. M'Donald, Pitrodie, Errol. *Chickens.*—1 and Cup, A. Shepherd. 2, A. Bowie, jun., Carnonatie. 3, Mrs. M'Donald.

COCHIN-CHINA.—*Cock.*—1, B. C. Urquhart. 2, J. Pollock, Bushy, Glasgow. 3, W. Hendry. *Hens.*—1, 3, and Cup, Mrs. J. Wood. 2, T. M. Hendrie, Inverness. *hc*, A. Cowie, Cromblybank, Ellon. *Chickens.*—1, J. Wood. 2, T. M. Hendrie. 3, F. Downie, Aberdeen.

BRAHMA POOTRA.—*Cock.*—1, J. Wood, Dunecht, Watertown of Echt, Aberdeen. 2, D. A. Pearson, Johnston, Laurencekirk. 3, Capt. Bunter, Tillery. *Hens.*—1 and Cup, Mrs. Gillison, Milngavie, Glasgow. 2, T. Raines. 3 and *c*, Capt. Hunter. *Chickens.*—1, W. Harvey, Sheffield. 2 and *c*, Capt. Hunter. 3, J. Mackie, Ellon. *hc*, R. Brownlie, Kirkcaldy.

HOUDANS.—*Cocks.*—1, Mrs. Bain, Aberdeen. 2, J. Logan, Eastshield, Lanarkshire. 3, B. C. Urquhart. *Hens.*—1, J. Mackie. 2 and 3, Mrs. Bain. *c*, J. Logan.

HAMBURGHS (Gold or Silver-pencilled).—*Cocks.*—1, J. Will. 2, H. Pickles, jun., Earby. 3, J. M. Campbell, Bonnykelly. *hc*, A. Scroggie, Oldwhat. *c*, A. Mathers, New Pitsligo. *Hens.*—1 and Cup, A. Pratt, Kirkcaldy. 2, H. Pickles, jun. 3, G. Laing, Persley, Aberdeen. *hc*, R. Fraser, Woodside. *c*, P. Campbell, Oldwhat.

HAMBURGHS (Gold-spangled).—*Cock.*—1, H. Pickles, jun. 2, J. W. Will. 3, J. Thom, New Deer. *hc*, J. Campbell. *Hens.*—1, W. Abel, Buxburn, Aberdeen. 2, J. W. Will. 3, Mrs. Brown, Creiff. *hc*, R. Mearns, Aberdeen. *c*, H. Pickles, jun.

HAMBURGHS (Silver-spangled).—*Cocks.*—1, G. Caithness, Carnoustie. 2, H. Pickles, jun. 3, G. Campbell, New Pitsligo. *c*, J. M. Campbell. *Hens.*—1, H. Pickles, jun. 2, J. W. Will. 3, J. Logan. *c*, J. Annand, Stoneywood, Aberdeen.

ANY OTHER VARIETY.—1, H. Pickles, jun. 2, J. Logan (Crève-Cœur). 3, W. Harvey. *c*, B. C. Urquhart (La Flèche).

GAME BANTAMS.—*Cock.*—1 and Cup, J. W. Will. 2, T. Raines, Bridge Haugh, Stirling. 3, R. Brownlie, Kirkcaldy (Black Red). *hc*, J. D. Skeno, Queen's Cross, Aberdeen; Sir G. M. Grant, Ballindalloch; R. Frew, Sinclairton, Kirkcaldy. *c*, J. Dick, Dunphail, Forres (Black Red); T. Skinner. *Hens.*—1 and 3, R. Brownlie. 2, T. Raines. *hc*, J. Dick (Dorkings and Black Red). *c*, W. Horne, Buxburn, Aberdeen.

BANTAMS (Any other Variety).—1, T. Watson, Bridge of Earn (Gold-spangled). 2, Miss J. M. Frew, Kirkcaldy. 3, H. Pickles, jun. *hc*, J. Waddell. *c*, Master A. Frew, Kirkcaldy.

DUCKS.—*Aylesbury.*—1, J. W. Will. 2, S. Ford, Huntly. 3, Mrs. Hendrie. *hc*, A. Copland, Kintore. *c*, J. Clark. *Any other Variety.*—1 and 3, W. M'Knight, Boghead, Pitcaple. 2, A. Bowie, jun. *hc*, A. Valentine, Blackburn, Kinellar.

TURKEYS (Any variety).—1, Mrs. W. Auld, Nethermuir, New Deer. 2, J. Willox, New Deer. 3, J. Clark. *c*, Miss Taylor, Fichnie.

GEESE.—1 and 2, J. Logan. 3, J. Waddell.

SELLING CLASS.—1, L. M'Donald, Pitrodie, Errol (Dorkings). 2, P. Symon, Errol (Spanish). 3, A. Bowie, jun. *hc*, Mrs. Gillison; T. Gray, Fordyce, Portsoy; J. Clark. *c*, Mrs. Gillison; J. W. Will (Game).

PIGEONS.

POUTERS (Blue Pied).—*Cocks.*—1 and *hc*, J. Millar, Glasgow. 2 and 3, D. Stewart, Perth. *c*, G. Ure, Rosebank, Dundee. *Hens.*—1, 3, and Cup, G. Ure. 2, J. Miller. *hc*, D. Stewart. *c*, J. Hawley, Bingley.

POUTERS (Black Pied).—*Cocks.*—1 and *hc*, G. Ure. 2 and 3, J. Miller. *c*, J. Morrison. *Hens.*—1 and 2, J. Miller. 3, W. B. Van Haansbergen, Newcastle-on-Tyne. *hc*, G. Ure.

POUTERS (Red or Yellow Pied).—*Cocks.*—1 and *hc*, G. Ure (Yellow and Red). 2, J. Miller (Red). 3, J. Walker, Newark. *c*, W. B. Van Haansbergen. *Hens.*—1 and 3, G. Ure (Yellow). 2, J. Miller. *hc*, J. Hawley. *c*, W. C. Thomson, Broughty-Ferry (Red).

POUTERS (White).—*Cocks.*—1, J. Miller. 2, W. Rotherford, Edinburgh. 3, J. Grant, Edinburgh. *hc*, H. Yardley; J. Grant. *c*, J. Sharp, Johnstone. *Hens.*—1, J. Miller. 2, G. Ure. 3, J. Sharp. *hc*, J. Grant. *c*, F. M'Crae, jun., Aberdeen.

POUTERS (Any other Colour or Marking).—*Cocks.*—1 and *c*, J. Grant (Chequers and Mealy). 2, J. Morrison. 3, D. Stewart. *hc*, W. B. Van Haansbergen. *Hens.*—1, W. Rutherford, Edinburgh. 2, D. Stewart, Perth. 3, W. Moon, Edinburgh. *c*, R. T. Moon, Driffield.

CARRIERS.—*Cocks.*—1, 3, and Cup, W. Massie, Spalding. 2, H. Yardley. *hc*, T. W. Kilburn, Bishop Auckland. *c*, W. Hendry. *Hens.*—1, H. Yardley. 2, T. W. Kilburn. 3, W. Hendry.

SHORT-FACED TUMBLERS.—*Almond or Mottled.*—1, W. Harvey. 2, J. Hawley. 3, H. Yardley. *Any other Colour.*—1, J. Hawley. 2, F. M'Crae, jun. 3, W. Hendry. *hc*, J. Grant.

BARBS.—*Black or Dun.*—1, H. Yardley. 2, *hc*, and *c*, W. Hendry. 3, W. Massey. *Any other Colour.*—1, W. Massey. 2 and 3, W. Hendry.

FANTAILS.—1 and 2, G. Ure. 3, T. Rule, Gilesgate, Durham. *hc*, J. G. Spence, Edinburgh. *c*, A. Smith, Bronghty-Ferry.

JACOBINS.—1, W. B. Van Haansbergen. 2, J. Miller. 3, J. Hawley. *hc*, H. Yardley, Birmingham. *c*, T. Rule.

TRUMPETERS.—1, J. Miller. 2, J. Hawley. 3, T. Rule. *hc*, W. B. Van Haansbergen. *c*, T. Rule; J. Bawley.

TURBITS.—1 and 2, W. Hendry. 3, T. Rule. *hc*, W. B. Van Haansbergen. *c*, C. Anton, jun., York.

OWLS.—1, W. Harvey. 2, H. Yardley. 3, W. Goddard, Earlston.

NUNS.—1, F. Graham, Birkenhead. 2, T. Imrie, Ayr. 3, W. Symon. *hc*, W. B. Van Haansbergen. *c*, Master A. Ridpath, Edinburgh.

DRAGOONS.—1 and 3, F. Graham. 2, H. Allsop, Birmingham. *hc*, W. H. Mitchell, Moseley, Birmingham. *c*, W. Massey.

ANTWERPS.—1, H. R. Wright. 2, W. Hendry. 3, H. Yardley. *hc*, W. H. Mitchell, Moseley, Birmingham. *c*, T. W. Kilburn.

ANY OTHER VARIETY.—1, 2, and Timepiece, J. Miller. 3, J. Sharp, Johnston. *hc*, T. W. Kilburn. *c*, W. Goddard (Austrian Pouters (Black), and Ice Pigeons).

SELLING CLASS.—1, G. Ure (Red Pouter Cock). 2, W. Harvey, Sheffield. *hc*, J. Grant. *c*, — Hendry (Black Barb).

JUDGES.—For *Game*, *Dorkings*, *Brahmas*, *and Bantams*, Mr. John Anderson, Blairgowrie; for *Spanish*, *Cochin-China*, *Hamburghs*, *Ducks*, *Geese*, *and Turkeys*, Mr. Alexander Paterson, Airdrie; for *Pigeons*, Mr. M. Stuart, Glasgow.

BIRMINGHAM COLUMBARIAN SOCIETY'S SHOW.

THE sixth annual Show of this Society was held on the 19th inst. in the Town Hall Auction Rooms. There were seventeen entries more than last year. The competition was divided into two sections—viz., birds bred in 1870, and birds of any age.

In Class 1, young *Carriers*, a promising Dun was first, and a Black second; many fanciers thought these positions should have been reversed. Of Carriers of any other colour, a very promising bird was first, but sadly deficient in colour. In *Almonds* and *Short-faced*, a Yellow Wholefeather was first, a Kite second; an Almond and Red Agate were also shown. These four birds were good in head, eye, stop, bill, and carriage; in fact, such as might have reasonably been expected from the author of the article on the Almond in "our Journal." *Mottles* and *Rosewings* were good in marking. In *Jacobins* and *Trumpeters* there was no competition, so the prizes were withheld. In *Barbs* a very promising Black was first, and a good Dun second. *Dragoons* were a good class, White being first, Blue second, and Silver third. There were four of the latter colour in this class. Dun *Antwerps* were promising birds, also the Red Chequers, but the pride of place must be accorded to the first-prize Blue Chequer, by far the best bird in any of the classes. These classes did not present the severe competition that is usual at this Show through the strongest exhibitor having purchased the whole of the stock of Mr. Noyé, the rule of the Society being that all young birds must be bred by the exhibitor. The *Any other variety* class was a splendid one; Satinettes were first, Owls second, and the remainder consisted of Blue and Silver Swallows, Mains, and Baldpates.

In the division for birds of any age, in the class for *Carrier* cocks, Black or Dun, all the prize birds were Black. The first prize went to a wonderfully good-billed bird, the wattle of which was by many good judges considered perfection, narrow skull, eye wattle rather too small, good colour and carriage. For hens, Black or Dun, the first prize went to Blacks with good eyes, rather too light in bill, and looking rather overshown; second a Dun with a remarkably large eye, bill good, but not quite so straight as it ought to be. Of hens of any other colour, Blue, good in all points except colour, were first, Silver second, and White highly commended. This was the best-eyed bird of this colour seen for some time. *Pouter* cocks and hens call for no special remark. *Almonds* and *Short-faced Tumblers* were very good in every point, Almonds being first and Kites second. *Fantail's*, no competition. Of *Owls*, Blue English were first, and foreign Whites with black tails second. These should have been first, although the cock was deficient in frill. In *Mottles* and *Rosewings* the latter were first, a perfect match; Mottles second. A splendid cock was in this pair; the hen exhibited rather too much white. In *Saddles* and *Badges*, Blacks were first, Reds second and third, Blues highly commended. *Nuns* and *Archangels*, Black Nuns obtained all the honours. These were three grand pairs. *Barbs* good. Blacks obtained all the honours in this class also. *Dragoons.*—In Blue a splendid pair was first. In any other colour, Silvers were first and second, Yellows third. This was a grand class, all the winners were fully up to the standard set forth by the Society. Silvers and Whites were highly commended. Five pairs of the former colour were exhibited. *Antwerps* —Of Blue, a remarkably good pair were first, the others require age to mature them. Dun Antwerps were a strong good class, one exhibitor carrying off all the prizes, the portrait cock being in the first-prize pair. Blue Chequered were good and all well marked, all the prizes again falling to one exhibitor. Red Chequered Antwerps were well represented by some grand specimens.

The *Antwerp* cock class was the strongest in the Show, there being twenty-five pens. Duns were first and second; Blues third; Red Chequered and Blue Chequered were highly commended. A veteran eighteen years old was exhibited by Mr. Crosland in perfect health and condition.

In pairs of *Any other variety*, Brunettes were first, and had an extra prize given by the late Hon. Sec., Mr. Noyé. Blondinette Satin were equal first; Dentillettes and Silver Turbits equal second; Blue Turbits and English Owls were equal third; Blue Blondinettes and Turkish Rollers were highly commended. Eastern Blues, Satinettes, Mains, and Swallows composed the rest of the class. In the class for single birds, a Damascene was first, and a Blue Blondinette second. This specimen was in bad condition, or the positions would have been reversed. The bird is as small as an Almond, of a deep blue colour, with pink bars, and on the end of every flight feather is a spot of white the size of a horsebean, and every tail feather has the spot the same as the Satinette. A Red Barb was third. The remainder of this class was made up of a Swallow, Starling, Owl, Jacobin, Archangel, Magpie, and Capuchin.

The Variety classes were certainly the greatest attraction in the Show, and were well worth seeing, as most of the specimens sent over to England from Smyrna by Mr. Noyé were exhibited. Carriers, Almonds, Dragoons, and Antwerps were good, the latter especially so, as no exhibition as yet has produced such classes with such keen competition.

An Antwerp courier hen was exhibited as extra stock by Mr. Ludlow, the Secretary. She has won ten flying matches from Paris to Belgium, and is a remarkably good-looking bird. This is a proof that if the short, strong-billed Antwerps are trained from the nest they are as good flyers as their longer brethren.

In drawing these notes to a close, too much praise cannot be accorded to the Committee and members of this Society for the liberal manner in which they provide a show for public inspection, and give free admission to any respectable applicant, either by ticket or on production of his card. Upwards of three hundred tickets were taken at the doors, and fully that number of visitors were admitted without ticket. Such liberality ought to receive support, and many fanciers were surprised to hear that the Society was supported on so small a yearly subscription—namely, 6s.; the secret is, all are fanciers, all put their shoulders to the wheel, and therefore the expenses are small.

BRED IN 1870.

CARRIERS.—*Black and Dun.*—1 and *hc*, J. Watts, Hazelwell Hall, Birmingham. 2, H. Hallam, Lozells, Birmingham. *Any other Colour*—1, J. Watts.

TUMBLERS (Clear-legged).—1, E. D. Careless.

DUMFRIES AND MAXWELLTOWN ORNITHOLOGICAL SOCIETY'S SHOW.

THE twelfth annual exhibition of Poultry, Pigeons, and Canaries took place in the Mechanics' Hall, Dumfries, on the 17th and 18th inst.

In number of entries the Show was considerably behind that of last year, but in respect to superior quality the exhibition was one of the best, if not the very best, the Society has had. The arrangements were excellent, and reflected great credit on the committee of management, and the indefatigable secretary, Mr. John Maxwell. A very noticeable feature in the prize-cards was a new form of card for the first prizes in the Poultry classes. A very tastefully designed card has the particulars and class, and the date of the Show printed in gold on the margin, which is crimson or blue morocco leather. In the centre of the card is a beautifully executed coloured specimen of the class of bird for which the prize-card is intended.

The following is a comparison of the entries:—

	1870.		1871.
Poultry	229	Poultry	172
Ducks	31	Ducks	16
Bantams	67	Bantams	43
Pigeons	77	Pigeons	73
Cage Birds	129	Cage Birds	88
	533		393

The competition in Pigeons was nearly equal in the number of entries to the Show of last year, and in regard to quality was first-rate, as in some of the classes nearly the whole were highly commended. Of Carrier Pigeons there were five entries, and this class commanded a good deal of attention, the interest being, doubtless, stimulated by the feats which these swift-winged messengers are now doing at Paris.

Of cage birds there was a great falling-off in the entries, the number being 88 against 129 last year. Some of the Dumfries Canary champions were fairly beaten on this occasion, even the redoubtable James Thorpe, having only succeeded in gaining two first prizes and five seconds out of sixteen entries. Only four other prizes were gained by competitors in Dumfries and Maxwelltown. The rest of the prizes were won by exhibitors from a distance. The first-prize Goldfinch Mule was said by the Judges to be the finest specimen of its class they had ever seen.

GAME.—*Black Reds, Blacks, and other Reds and Blues.*—1 and 2, J. Brough Carlisle. *hc*, F. W. Thwaites, Carlisle; T. West, Eccleston, Lancashire *Chickens.*—1, J. Brough. 2, J. Harding, Dumfries. *hc*, D. Hardie, Priesthangh Hawick. *Duckwings, Whites, and others Greys.*—1, J. Brough. 2, R. W M'Cracken, Thornhill. *hc*, D. Harley, Edinburgh. *Chickens.*—1 and *hc*, T Davidson, Longton. 2, D. Harley.
DORKINGS.—*Silver-Grey.*—1, J. Cunningham, Dalbeattie. 2, A. Skirving, Croys, Dalbeattie. *hc*, Com. G. F. Lyons. R. N. Kirkmichael; R. Reid, Hollinhirst, Canonbie. *Chickens.*—1, J. Thomson, Blaiket. 2, Mrs. Hume, Auchendolly, Castle Douglas. *hc*, Miss M. Johnstone, Terregles; Miss M'Holme, Troqueer; D. Hardie. *Any other Colour.*—1, R. Reid. 2, D. Hardie. *hc*, A. Shepherd, Meigle. *Chickens.*—1, Mrs. J. Bell, Hillowtown, Castle Douglas. 2, R. Reid. *hc*, A. Shepherd.
SPANISH.—*Black.*—1, A. Shepherd. 2, W. Paterson, Langholm. *hc*, H. Wilkinson, Earby. *Chickens.*—1, W. Paterson. 2, H. Wilkinson. *hc*, A. Walker, Kilmarnock; A. Shepherd.

CANARIES, &c.

SCOTCH FANCY.—*Yellow.*—*Cocks.*—1, R. Bryden. 2 and 3, T. Scott, Carluke. *Hens.*—1, J. Thorpe. 2, T. Scott. 3, W. Welsh, Dumfries. *Buff.*—*Cocks.*—1 and 3, T. Scott. 2, J. Thorpe. *Hens.*—1, T. Scott. 2, J. Thorpe. 3, J. M'Quhae, Maxwelltown.
PIEBALD.—*Yellow.*—*Cocks.*—1 and 3, T. Scott. 2, D. Gibson. *Hens.*—1 and 2, T. Scott. 3, J. Knocker, Southwick. *Buff.*—*Cocks.*—1, T. M'Millan, Wishaw. 2 and 3, T. Scott. *Hens.*—1, R. Bryden. 2, T. Scott. 3, R. M'Innes.
GOLDFINCH MULES.—*Yellow.*—1 and 3, J. Coupland. 2, J. Thorpe. *Buff.*—1, A. Law. 2, J. Little. 3, W. M'Donald, Newabbey.
GOLDFINCHES.—1 and 2, J. Thorpe. 3, A. Martin, Castle-Douglas.

JUDGES.—*Poultry:* Mr. R. Teebay, Fulwood, Preston. *Pigeons:* Mr. J. Huie, Glasgow. *Canaries:* Mr. W. Allison, Glasgow, and R. Crawford, Kilbirnie, Ayrshire.

THE SCOTTISH COLUMBARIAN ASSOCIATION, EDINBURGH.

(*Concluded from page* 40.)

IF the Pouter classes at Edinburgh manifested the constancy of the Scotch fancier, no less did the other varieties demonstrate his versatility. These appeared in numbers but little inferior to the late Glasgow gatherings, and in quality fairly representative—facts the more encouraging seeing how closely the Exhibition followed upon those of London and Birmingham. It will not savour of indifference to the general classes, whose characteristics are so often discussed, to single out Fantails for honourable mention. They indeed are rapidly becoming a speciality, only second to Pouters, with fanciers north of the Tweed, whose taste has led them to the cultivation of those smaller varieties endowed with so many graces of form, carriage, and gesture, and differing in many essential respects from the woodcut in a late number of this Journal. The unrivalled excellence and charm of the Fantails were generally admitted; their unceasing tremulousness so desired by competitors, and their dainty, tiptoe, gyratory motion, exciting amongst visitors the liveliest curiosity, and in some an almost pitying wonderment. Few could be persuaded that these highly valued properties were natural ancestral features, and those who conceded that possibility evidently cherished the conviction that Darwinian principles must at some time have got into strange alliance with habits of the "Grecian bend" order. If it would not seem hypercritical, exception might be taken to the provision of separate classes for young birds as superfluous, and to the small number of coloured specimens appearing—a deficiency, however, to be easily rectified, but at no sacrifice to the peculiarities so apparent in the Whites. Both the President and Vice-President have long been leaders in the endeavour to popularise the Fantail classes, and both must have been gratified with the success now recorded, quite irrespective of their honours as prizetakers.

The prize list, already published in full, included many new and welcome names in addition to those of familiar note, and the judgment was entrusted to Messrs. Corker and Wolstenholme, who, with that fatality which so frequently clings to the office of judge, were fettered in their labours to the loss of some four or five hours of precious daylight. The maturity of every arrangement could not reasonably be expected on a first occasion, but, with experience gained, the Association must be among the first, by stringent measures, to protect both judges and competitors from prejudice; and in a place of such accessibility as Edinburgh no excuse must be admitted for late arrival of birds, especially in the case of local exhibitors. Of the awards themselves, it must ever be borne in mind that in any show of sterling quality many birds of great stud value will remain unplaced; and although first prizes should proclaim the "Derby cracks" for the year, yet secondary awards in some cases may stand on a similar level of merit, the placing indicating no more than the tendency of taste in the judges for the time being.

Future Prospects.—This, the first show of the new Association, cannot be dismissed without some general and anticipatory remarks. The change from Glasgow to Edinburgh for the annual Scottish tournament was admittedly an experiment, but one more than justified by the event. It implies no disunion amongst the competitors themselves, but rather is the natural outcome of their growing interests. In short, the Edinburgh public has proved so sympathetic, that what before was compassed by the arduous and costly effort of the fanciers alone will in future be accomplished with all the advantages of external support and appreciation; for after an exhibition so pleasantly inaugurated Edinburgh will look forward to a yearly renewal of the gratification, while that capital better meets the convenience of southern friends, who are ever cordially welcomed across the border.

Whatever may be the plans under discussion for future adoption, there is a path open to the Scottish Columbarian Association especially worthy of its notice, and more than suggested by the estimation now attaching to the fancy Pigeon interest. For some years Scotland has

led the van in the superior arrangement and conduct of competitive exhibitions, and while Edinburgh displays an unflagging zeal in the same direction, much may yet be done to develope the art of exhibiting, to infuse into public shows a character of refinement, and to excite a higher regard for tasteful surroundings, particulars in which the Association has considerable opportunity for distinguishing itself and of becoming an influence for good. And in such a care for externals a harmony may be discovered, for the culture of fancy Pigeons strongly appeals to the artistic sense. Without taste, without nice perception, without superior powers of discrimination and comparison, as well aspire to be an artist of distinction as a successful fancier, no matter what the variety selected for cultivation.

Tasteful and appropriate exhibition arrangements should follow as by natural sequence; and shows ambitious for national or metropolitan distinction, so far from being behindhand in such matters, must set the fashion. Edinburgh has begun well, and seems thoroughly to understand, in common with the National Peristeronic Society and the London Exhibition Committee, that the arena of competition, the furnishings, the style and distribution of the pens, the care bestowed upon the birds, and, pre-eminently, the comfort and convenience of the visitors, are all elements for good or for evil, and greatly influence the public. The adoption and maintenance of worthy exhibition surroundings will not fail to have a favourable reaction on the birds. Competitors will more than ever realise the importance of bringing their birds to exhibition in "race horse" condition—bright, sleek, and sound, and by sheer contrast a death blow will be dealt to that jaded, overworked, and bedraggled appearance which is the very negation of the artistic or the refined.

Directing attention, therefore, to the "internal" rather than the "local" surroundings as most concerning the fancier, the Scottish Columbarian Association, in conclusion, may be congratulated on its merited success, and may be commended to a further development of those exhibition refinements so consonant with the pursuit as an art, and so appealing to the uninitiated.—W. Volckman.

A PIGEON FANCIER'S NOTES BETWEEN BIRMINGHAM AND SMYRNA.

I am at Smyrna, after fifteen years' life in good old England the memory of which I shall cherish for life, while I will retain, so far as it depends on myself, the friendship and brotherly love of those I proved true, looking with joy at their portraits, and the souvenirs they have honoured me with. I embraced the first opportunity of fulfilling what I promised to my fellow columbarians, and shall always be ready to forward all I consider desirable acquisitions to my fellow fanciers at large, on condition that orders from unknown correspondents must be endorsed by the approval of the Editors of this Journal, or my successor, Mr. J. W. Ludlow, Edward Place, Vauxhall Road, Birmingham.

Commencing to sketch my journey, the first country I entered on leaving England was Belgium, the mother of the Antwerps. What a chance, I thought, to stay in Brussels till the Pigeon market-day (Sunday), to see if I could procure any suitable specimen of this fast tribe, to send to my Birmingham friends for crossing purposes? I visited the market, which was very largely attended, being the day of the Belgian Independence, but in vain, as there was not one bird worthy of my purpose. I witnessed the departure of nearly all the birds from the cages of their owners, who liberated them to lighten their burden homewards, and immediately afterwards I took my departure through Germany (sadly interrupted by the various trains to and from the seat of war), for the Austrian capital, in which I stayed long enough to see if I could find there any acquisition of Pouters (pigmy), as it is of no use to look for improvement upon the specimens in the possession of our Scotch and English fanciers. There were some pretty birds of this tribe, but I was advised not to risk sending them, as it was not very safe for human beings to find their way through Germany, much less birds. Losing all hope, I resumed my journey by train, then by the romantic Danube, and then by the Varna railway to Varna, and from Varna through the Black "frightfully Black" Sea, to Constantinople, the most noble and beautiful city in the world seen from a distance, but the most filthy and barbarous in itself! Here I found a few pretty birds, but knowing that I was going to their birthplace, where I had, seventeen years ago, known the most beautiful of all Toy Pigeons, including the exquisite Satinette, which I extensively introduced then, I passed them, and resumed my journey. Arriving in Smyrna, I commenced at once inquiries for my old friends and fellow fanciers, in the absence of Pigeon dealers; but, alas! few—very few—of my old friends are left. I contrived, however, within a month to procure twenty-four pairs of new varieties—Toy birds—and forwarded them by the steamer direct to Liverpool, for my friend, Mr. Ludlow, to be disposed of to members of our Society, and I am gratified to find the result was all I could wish. I intend to send in my next communication full descriptions of the birds I sent, and of those existing in this part of the world.—H. P. Caridia, *Smyrna*.

BIRMINGHAM MUFFED TUMBLERS.

I beg to convey through your Journal my thanks to the Birmingham Columbarian Society for the additional information relative to these Tumblers, contributed in reply to my own observations; and I have to acknowledge the compliment of the very explicit nature of this information upon peculiarities the Society state to be not worth mentioning, since exemplified at any Pigeon shop—in Birmingham, I assume—by birds sold at the cheap rate of 10s. per dozen. As I do not frequent the Birmingham Pigeon shops I feel favoured by this intimation, and hope it may not be profitless to myself and other strangers to the Birmingham mart, curious as to the blood of the Tumblers confessedly exhibited and identified with the Tumblers the subject of our notice. The summary, if I understand the Society, is that birds with the clear and muffed legs and the odd eyes do appear in the broods from parent birds the opposite in each peculiarity, or in apparently reverse relation of parents to offspring; and that the diversity of clear and muffed legs is to be attributed to a back cross of the Long-muffed with the Clear-legged Tumbler to break or diminish the muff of the progeny. Thus, that extreme variations of leg occur —*i.e.*, a clear, a diminished, and a long muff, from the same parentage, though such parentage be diverse itself, and so betrays its own pedigree of the back cross inferred; but that the odd eye is a mystery, and called a "bull eye," and is black, and not hazel, as stated by me, which eye—the evil eye—the Society, however, will "get rid of" as soon as practicable. Very well. The Society will forgive me repeating, though, that this odd eye is hazel—*i.e.*, the iris is hazel and the pupil black, else my own eyes are "colour-blind"—an infirmity the Society will pardon me the vanity of repudiation. Precisely as the gravel or pearl eye is so termed from the colour of the iris, so is the odd eye in question, from its iris, properly called a hazel eye. Substantially, therefore, the Society and I are agreed upon the peculiarities I submitted to be omitted in a former contribution from the Society, and now amply supplied.

The Society complains rather jealously and testily of some who would "anathematise" the Muffed Tumbler, and very rightly retorts that it would be wiser to "improve" this Tumbler until of the excellence in size and shape of young England's standard bird—our old English Tumbler. And so should I, as an Englishman, like to see the Muffed Tumbler a model bird of its class, for already I am proud to affirm that my own Tumblers of this variety, not "Pigeon-shop" birds, are no despicable specimens, nor aught loth to show their mettle by flights sky high and acrobatic gambols, the admiration of the neighbourhood. The Society, too, I must not omit to notice, now challenges comparison with our English Tumbler, in picked birds, in round "Brummagem" style and excusable laudation of its own ware.

I will try to approach the standard of the old English Sky Tumbler by another cross over to young England's fancy, so as to preserve the muff and retain the spirit of the Birmingham and old English Sky Tumbler in the progeny. The present Birmingham Muffed Tumbler comes from Continental or European (be it Dutch or German) ancestry doubtless, but grafted on our own stock of English blood, it will neither belie nor disgrace its family tradition.—Reader.

P. S.—The hazel eye is very likely transmitted from a hazel-eyed Bald, or a Magpie with dark eyes, crossed for flight in the former, and feather in the latter bird, or they may be accidentally so crossed.

COLCHESTER AND PORTSMOUTH RABBIT SCHEDULE.

I am surprised to find that the fancy variety men who have written so much upon the injustice done to the variety classes at most shows, should now praise the one-sided schedule of the coming Colchester Show. The sum of £12 is offered in prizes, only £3 going to the Lop-ears, the other £9 going to the fancy varieties. The extra weight to be paid for in carriage to and from the show will be double that of the single fancy Rabbit. Let us compare the two varieties. The very best fancy Rabbit there is you can buy for £2 or under, but to purchase a good Lop-eared Rabbit you must give from £5 to £10; also, there is no difficulty in breeding a good fancy Rabbit, but you may try for years before you can breed a good Lop-eared Rabbit. I contend that on account of value alone, the Lop-ears should always take the preference in a schedule, but at the same time I would do justice to the variety classes. But Mr. Hudson has just shown us he would do the opposite. Of the two schedules, I maintain that that of Portsmouth is the better. The Colchester Committee will find out their mistake when the entries close.

If the Rabbit fanciers of England would have the whole matter put on a just level, they must co-operate, and neither side should try to swamp the other. I have often thought it would be a good plan to have a "United Kingdom Rabbit Club" formed, say each member to subscribe 1s. a-year; to appoint a secretary to correspond with each poultry show committee, to suggest classes for the shows, and attend

to the interest of the Rabbit fanciers. If something of this kind were carried ont, it would, I doubt not, put an end to all jealousy betwixt the various fanciers, and they would increase both in numbers and respectability.—M. Millington, *York*.

SILVER CUPS AT THE CRYSTAL PALACE CANARY SHOW.

What does it mean when yon are told to "wire in?" Is it an electrical, mechanical, physical, or mental operation? I can find it in no dictionary, not even in the newest claiming to have some thousands of new words, nor in any published list of obsolete terms. I am told it is an English way of rendering a common expression found in I forget what language (but it is written in characters about as legible as those mysterious Arabian-Nights-looking blotches on tea chests), and is a verb neuter, signifying to eet about a thing with energy, but that it conveys more meaning than words can tell, something like our word "humbug," than which a more expressive word we have not.

In the columns of "our Journal" there is to-day a statement from "Yours ever, H. A." respecting the above, from which will be seen what is intended to be done. The cups can all be raised if the snpporters of each division to which a cup is appropriated will only "wire in." Isn't it a famous word? I have the Belgian piece of plate in hand, and if Belgian fanciers will at once send in their donations to me, or, better still, direct to Mr. Ashton, their cup can soon be made a certainty. I am aware that the classification of the Belgians is neither on so extended a basis, nor have they so liberal a prize scale, as more favonred varieties have extended to them; but the indifference of exhibitors is to blame for this, as I am sure a proper representation made in the proper quarter would remedy this defect. This should not deter any from subscribing a mite, but all should "wire in" with a will, and snpport what is undoubtedly the show of shows, and by a display of enthusiasm induce Mr. Wilkinson to make such an alteration in the schedule next year as will meet the views of all classes of exhibitors.

Mr. Stansfield, of Bradford, who has the Mule cup to fill up, writes me he has about a hundred names on his list. Well done! I can only repeat my sloggan "Wire in," and most likely you will have enough for two cups, which assuredly there should be, noless Jonques and Mealies are to be weighed in an even balance irrespective of colour. And the "Any other variety" class, containing as it does most extraordinary hybrids, will it have a separate cup? If ever a man had a "call" (I think that's the right word), a call to "wire in," Mr. Stansfield is the man, and the "Any other variety of Mnle" class is his field of labour.

Remember, all who are collecting for cups, the Show will open on February 11th—that is, in a fortnight; and you, whose name is legion, who intend to respond to "Yours ever, H. A.," in this movement, send in your donations at once, that on the opening day the cnps may decorate the table in the snng little corner behind the door of the tropical department.—W. A. Blakston.

As the Crystal Palace Canary Show is now not very far distant, allow me through your valuable paper to inform Canary fanciers that I am again trying to raise money for silver cups, as last year; bnt as the time is so short I have, instead of doing it all myself, asked different fanciers to take a class each, and the following have most kindly consented:—Mr. Blakston for Belgians, Messrs. Moore and Wynne for Norwich, Mr. Stansfield for Mnles, Mr. Waller for London Fancies, Mr. Harrison (I think), for Cinnamons, and myself for Lizards. I hope that all intending exhibitors will not delay, but send in their names and the amount they wish to snbscribe at once. I think those who won cups last year ought certainly to subscribe this year.—Howarth Ashton, *Polefield Hall, Manchester*.

Northampton Poultry Show.—Your readers will see by an advertisement in this Journal, that we hold our second annnal Show on the 8th and 9th of March. About fifty classes will be open for competition—twenty-five for poultry, and the remainder for Pigeons and Rabbits. The prizes will be uniform throughout, unless any special prize be subscribed for. We have introduced a class for Malays, and hope breeders and admirers of this class will snpport us. We can at present afford only two prizes for the best and the second best cock and hen, but we think it needs only to be mentioned to bring us sufficient to snpport the class with four prizes—viz., for the best and second best cock, and the best and second best pair of hens, the same as in our other classes for large fowls. In the Pigeon classes there will be two classes for Poutere instead of one, and the same for Carriers.—William Humphreys.

FOUL BROOD.

To the controversy so ably carried on by Mr. Lowe and the "Devonshire Bee-keeper," seven years ago, we are indebted for much of the valuable information that has appeared in the pages of "our Journal" on the subject of foul brood. The former never had any experience of the complaint, and believing that bees enjoyed immunity from anything of the nature of an epidemical visitation, endeavoured to show that all the evils complained of by the latter might be traced to an improper interference with hives, whereby the young larvæ were killed and left to rot in their cells. In elucidation of his views he drew an amusing picture of the doings of experimentalists, but in writing that article, which bore all the features of a caricature, I am well assured he had not the slightest intention of giving offence to anyone. Taking it for granted that the laws of Nature had been violated, and that the appearances which presented themselves in Mr. Woodbury's apiary were due, not to the presence of disease proper, such as scarlet fever or small pox, but to some evil or defect artificially created, he intimated that health would certainly be restored by complete excision of the affected parts.

The question, therefore, in the first instance, to be solved was this, Is foul brood a real disease, a spreading epidemic, and infectious? or is it merely an artificial malady, caused by chilled and dead larvæ, and one that can be eradicated by a simple removal of the evils introdnced? To determine this point certain experiments were undertaken, which have been detailed in the Journal, and I think it was clearly proved in the cases described that foul brood was communicated by infection, that it found its way into hives where no chilled and dead larvæ were previously present, that it could not be cured by any amount of excision of the tainted combs, and that it was a true disease—a pestilence extending itself—and as contagious as any which afflict the human family.

Now I, for one, will not charge Mr. Lowe with either ignoring or disbelieving the evidence adduced on the subject, although he may not have stated in the Journal that he is completely satisfied with the proofs that have been offered. If I mistake not he is ready to assent to the view that foul brood is of the nature of a pestilence, infectious, and incurable by excision, and wishes us to regard his present contention as relating entirely to its causation or origin. It has been shown by Mr. Woodbury and others that chilled brood, even in a putrefying state, when placed in a hive does not necessarily produce disease; but whilst accepting the fact, and also admitting that in the summer season a strong swarm will speedily clear out all decaying larvæ, I yet do not think I am precluded from holding the view that putrescent matter may have much to do with the introduction of foul brood into our hives.

The theory which finds most favour at the present time is that which ascribes putrefaction to the presence of living organisms developed from germs floating in the atmosphere. In the dead subject these microscopic objects find a suitable nursery for their propagation; and I can conceive that under peculiar conditions of temperature, moisture, &c., and whilst they are being developed, there may be evolved an element of destruction—call it a virus, if you like—which, fastening upon young larvæ and killing them, may produce putrefaction of a specific character, or true foul-brood corruption. It may be said that no such metamorphosis in the character of putrefaction has ever been witnessed, and that a corruption which is infectious has not arisen from corruption non-infectious. Well, fever may not be directly caused by filth, but the disease is, nevertheless, frequently generated amid unsanitary conditions. There seems to be no reason for thinking that some particular combination of elements may not give rise to diseases of the zymotic class, although their prevalence in any locality may often be due to infection or contagion. It is said that true Asiatic cholera, without infection being present, spontaneously arose in the House of Industry, at Coventry, in 1838, and many are of opinion that this fell plague has its origin in the exhalations arising from animal and vegetable matter in a state of decomposition. Now, when making some remarks on the theory of Dr. Preuss I stated "with a *caveat*" that there appeared to be some cases of weak hives that were healthy allowing in spring or autumn chilled brood to decay in the cells without any attempt to remove them, and that injurious results had followed the use of combs from which putrid larvæ had been extracted. But I am not satisfied yet with the proof I possess, and I would be glad if any apiarian who has made observations on the point, would record his experience.

In regard to the cure of foul brood, there can be no doubt that chloride of lime has sufficient power to cope with the fatal influence, whatever that may be. It was used with complete success by the "Devonshire Bee-keeper," in the purification of his boxes, and his facts have been fully corroborated. It cannot, then, be said we are still without a remedy, but we would like to know of an agent that we can make use of for

disinfecting the combs. Dr. Abbe informs us that it may be done by means of hyposulphite of soda.

As to overheated and suffocated brood causing disease, which is the doctrine advocated by "A Renfrewshire Bee-keeper," I can say little, having had no experience in the matter; but if bees are up to the mark it is difficult to see why they should permit dead larvæ, during summer weather, to rot in the cells without making a hasty and determined effort to remove them. Perhaps I am wrong in supposing they are not removed, for it is not to the presence of decaying bodies but to the mixing of condensed moisture with unsealed honey that evil is ascribed; but I would respectfully ask whether it is the case that honey in a hive so mixed with moisture ferments, and whether it is found by experience that fermentation is a consequence of mixing sealed with unsealed honey?

I do not remember witnessing the facts stated, nor have I seen honey in the unsealed cells covered with a white mouldy fungus, although I have seen the fungus often enough in cells containing bee-bread. In a wet season the honey collected abounds in water or moisture, but it does not ferment.—R. S.

OUR LETTER BOX.

Inquiry (*W. M., A. F., and Others*).—We are glad that most of you escaped by wisely requiring references or prepayment. With those who sent their fowls and have not been paid for them we cannot sympathise. If a post-office order payable ten days after date were required to be sent before the birds were forwarded, both seller and purchaser would be protected. Payment could be stopped if the birds were not approved. It may be useful to observe that the party who applies for birds but will not prepay, writes from various places—Aldgate, Wild Street, Culford Road, &c.

Bristol Poultry Show.—"In the report of this Show inserted in the Journal of January 12th, of Dark Brahma hens, it is stated, 'The cup was taken by the first-prize Birmingham hen, though only highly commended at Manchester the week before; such is the uncertainty of judging.' This is not correct, the Birmingham first-prize hens were not shown at Bristol. The hens that won the cup at Bristol were the same pair that won the first prize at Manchester, so that the uncertainty of judgment belongs to your reporter.—Richd. Teeday."

Best French Fowls (*E. V. O.*).—Beyond doubt we should recommend you the Crève-Cœurs. They are the best French fowls. They are more civilised than the Houdans, and their eggs are one-half larger than they are. You can keep a sufficient number of breeding birds in the space you name, to exhibit with such success as their quality may warrant. There will be nothing in the locality in which they are kept or its space to prevent it, but you will not find it large enough to rear chickens.

Malay Characteristics (*Yorkshire*).—Where all the points and characteristics of a fowl are required, we can hardly spare the space necessary for the description of them. The best plan is to buy a book that describes them. We will give an outline. The Malay cock should describe three downward curves; one from the head to the top of the shoulders; the next from the shoulders to the tail; and the last from the insertion of the tail to its extremity. The comb should be flattened on the head, but be fixed perfectly tight. The feathers should be as hard as metal and very scanty; the point of the breastbone and the exposed joint of the wings should be red and naked; the throat skinny and divested of feathers. The same rules are required in the hen, save the third curve, which may be dispensed with.

Cross Between Dorkings and Brahma Pootras (*R. H. F.*).—The best cross is from a Brahma cock and Dorking hens. It depends on the time of year. In November, a fortnight; in January, six weeks. If the fowls are not laying it is immaterial.

Fowls for Small Space (*A. R.*).—In such a place as you describe, we should advise you to take to Dark Brahmas. They are more than average layers, and are amongst the hardiest fowls we know. A small space will serve for the adults, but you cannot rear chickens in a small place.

Hardy Fowls (*Sarah Ann*).—If you want hardy fowls for general purposes we advise you to keep the Brahma Pootra. If you look for your profit from eggs you must take care to keep pullets of the proper age every year. Your feeding is good, but we do not like rice for food. Greaves are good at times, but as general food they are too stimulating. If your fowls have a grass run, ground oats slaked with water morning and evening, with whole corn for a midday meal, alternately barley and maize, are good-enough feeding. If you are getting eggs now you have no cause to complain; you are more fortunate than many. Feed your old Ducks on oats put in water with a sod of growing grass. Your young ones will want oatmeal or ground oats, and a little raw meat at times will help them if they are hatched early. It would be too long to go into the question of fattening fowls. You had better procure Baily's book, it treats at full length of the process.

Spanish for Exhibition (*Young Exhibitor*).—On no account show the cock with a falling comb; it is a disqualification. The bird with the upright comb and the smaller face is in all probability preferable in every way. If the breastbone be as slightly crooked as you say, we think it unimportant, and redeemed by such large size at an early age. The dead white face would be the most desirable if it be of an average size and not too small. Blue in the face of a pullet may be excused, but there is no hope for eye a blush of red.

Spanish Cock's Excess of Face (*A. C. J.*).—Your Spanish cock has an *embarras de charmes*, and is suffering from excess of beauty. The only thing you can do is to cut some narrow strips of good adhesive plaster, and stick the eyelids back, so that they shall not conceal the eye.

Cochin's Comb, &c., Black (*Large*).—It may be they are frosted, or the bird may have picked up something poisonous; either would cause the appearance. The treatment will be to rub the comb with strong camphor ointment, to give a strong dose (a good table-spoonful) of castor oil, and to follow with bread steeped in strong ale twice per day for three days.

Floor of Roosting-house (*R. H. F.*).—It may be of crushed chalk over coal ashes, as you mention, or fine gravel, with 2 inches of sand over. The floor requires no washing, but to have the fowls' excrements raked off every morning. The surfacing of sand should be entirely renewed once a-year.

Blue on White Rumps in Blue Dragoons (*Pinch Eye*).—This was the subject of a very lively discussion in our pages just five years ago, chiefly between Mr. Jones Percival and Mr. Ludlow, the former advocating the blue rump, the latter the white; each disputant as usual maintaining his own opinion to the last. Singular to say, the Indian Blue Rock has the dark rump, the European the white. As to Dragoons, supposing two pens were of equal excellence, but the one had blue rumps the other white, we think that the former being the rarer colour (and rarity in fancy birds goes a great way always towards constituting excellence), ought to win the prize.

REMARKS.

18th.—Slight fog in morning; rain at intervals throughout the day.

19th.—Overcast, with rain nearly all day; fog in evening.

20th.—Misty morning, with occasional dripping showers.

21st.—Dull and overcast, but no rain during the daytime; a little wind after 9 P.M.

22nd.—Foggy morning; mingled snow and rain at 10 30 A.M.; at 5 P.M rain began, and from 8 to 10.30 P.M. it fell heavily.

23rd.—Overcast, with showers at intervals.

24th.—Dull. Flakes of snow about 2 P.M., and a moderate fall in the evening, whitening roofs and nonconducting materials (such as planks, &c.), resting on ground. Fresh wind from N. after 10 P.M.

The week is principally noticeable for an almost unbroken canopy of clouds, continuous cold rain, extreme dampness, and singularly uniform temperature, the range at 9 A.M. being less than 2°, and the entire weekly range only 13°—viz., from 30.1° to 43 1°.—G. J. Symons.

COVENT GARDEN MARKET.—January 25.

We are now experiencing the effects of this disastrous war in being shut out of our Paris markets for Lettuces and similar things, which are not to be obtained of good quality from our own growers. Trade generally has experienced a slight improvement, and good descriptions of Grapes and Pears are in greater demand. The Potato trade report large arrivals both by rail and coastwise. Prices, however, remain much the same, although the stocks are heavy.

POULTRY MARKET.—January 25.

It is a long lane that has no turning, and the market is getting clearer, When the House meets we look for better things, as good as may be pending the abominable war. We have no doubt small supplies of good fresh poultry will make remunerative prices.

From observations taken near London during forty-three years, the average day temperature of the week is 45.6°, and its night temperature 32.3°. The greatest heat was 57°, on the 3rd, 1850; and the lowest cold 10°, on the 5th, 1838. The greatest fall of rain was 0.67 inch.

EXOTIC FERNS.

DURING winter, when the snow lies thickly on the ground, and trim lawns are covered with a sheet of dazzling white, it is very refreshing to rest the eye for awhile on a mass of verdure, and it is during such a period that a healthy collection of exotic Ferns is most appreciated; the different species of Palms are noble and worthy companions to them, both are highly valuable for decorative purposes in winter, and well do they repay us for the requisite attention to keep them in a healthy flourishing condition. The Palm claims our esteem for its elegant, and in many cases majestic, appearance; the Fern for its grace and infinite variety, both in the form of the fronds and different shades of green, ever changing, ever pleasing to contemplate. In a previous article in your columns I gave in detail my method of cultivation, and some description of the most desirable kinds; since that time many fine sorts have been introduced to our notice, more experience has been gained, and the present dull dreary period of the year reminds us of their value to add grace, beauty, and dignity to our stoves, apartments, and conservatories.

The crossing of Ferns by natural and artificial means has been doubted by some, but the mass of evidence gradually accumulating must make hybridisation an established fact. There is a wide field of interesting and instructive study in the fructification of Ferns; at what time hybridisation is effected, whether in an early or late period of development, I know not; of this, however, I have no doubt, that if kinds of Ferns bearing affinity to each other are placed in a warm stove in juxtaposition, and if they remain so during the early and late stages of fructification, and until the spores are scattered in the air, there will be found young Ferns springing up in abundance bearing a form intermediate between their parents. Thus Gymnogramma ochracea and G. tartarea will produce intermediate forms dusted with sulphur-like powder; the progeny are not equal to either of their parents in ornamental effect, but I have grown dozens of them to a large size. Lomaria gibba and Blechnum brasiliense have produced numerous intermediate forms, and plants raised from this cross have been named. Lomaria intermedia, again, has taken with L. ciliata. The interesting forms of Scolopendrium and others of our native Ferns, exhibited by E. J. Lowe, Esq., of Highfield House, Nottingham, at the first meeting this year of the Royal Horticultural Society, may be sports, and selections, doubtless, they are, excepting the beautiful Adiantum Capillus-Veneris *var.* admirabile, which I could easily believe to be a cross.

There is yet another instance of peculiarity in Ferns—that most beautiful of all Adiantums A. farleyense can only be propagated by division, its fertile fronds producing a distinct variety, A. scutum. There are two very fine recently-introduced forms of Lomaria gibba—viz., L. crispa and L. Bellii. The latter seldom produces fertile fronds, which is much in favour of its usefulness as a decorative plant, as in the normal form the pinnæ are much narrower on fertile fronds, and they also decay much sooner; in L. crispa the fertile fronds differ but little from barren ones in appearance, and there are both barren and fertile pinnæ on the same frond. I sowed spores of L. crispa in November last year; and in a close, moist atmosphere, with a minimum temperature of 60°, the young plants are now developing themselves.

Of late years there have been some very fine species of Adiantum introduced, and assuredly the best of all is A. farleyense. When this species was first introduced it was in many cases coddled under bell-glasses, where its proportions could not be seen, or its waving gracefully-drooping fronds and elegant pinnæ, deeply fringed at the edges, could not be appreciated—it is grown here in an ordinary stove, and, under proper management, is as free in growth as any of the genus. The plant shows to the best advantage if the pot in which it is grown is placed on an inverted pot of the same size. The fronds are very delicate, easily injured or even destroyed by tobacco-smoke which would not injure any of the others; or, if exposed to a draught, such as from opening and shutting the door, or placing the plant too close to the side ventilators, it will not give satisfaction. It succeeds well in a compost of equal parts of turfy loam and turfy peat torn to pieces by the hand, with a liberal proportion of silver sand. Careful watering is also an important element of success. The other day I measured a noble plant of A. farleyense, in Messrs. Veitch's nursery at Chelsea, having a spread of fronds 4 feet across and 4 feet high. The variety, A. scutum, has been grown here for several years; it is a very desirable Fern; the fronds are not so very susceptible to atmospheric influences as those of A. farleyense, but it does not grow so freely, nor does it make such handsome specimens. A. peruvianum is a stove Fern of free growth, somewhat resembling A. trapeziforme, but having its fronds, which are thrown up freely, more pendant; it is very elegant in growth, and a desirable acquisition. During last season I noted a very desirable variety of Adiantum Capillus-Veneris named maximum; the pinnæ are much larger than in the normal form.

There was also a very fine Davallia, perhaps the best, introduced to the public last year, and one of the most beautiful of stove Ferns; it is well named Mooreana. It has pale green gracefully-arching fronds over 2 feet in length. As it is easily cultivated and free-growing, it ought to be in the most select collection of Ferns. There is also Gymnogramma Pearcei, a very pleasing species with finely-cut fronds. There is in the hands of Messrs. Veitch a very beautiful miniature tree Fern, Leptopteris Wilkesiana; the imported plant has a stem a foot high, the fronds are very thin in texture, and the plant requires a moist warm atmosphere. The best way to grow Leptopteris, and the nearly allied genus Todea, is to have a small glass structure erected in a shady part of the greenhouse, and if some arrangement can be made to plunge the pots in sand or shell gravel, the plants will require but little water, as the glass case must be kept close. Leptopteris Fraserii and superba, Todea pellucida and

T. arborea, do well in such a place. I tried to grow T. pellucida under a bell-glass in a stove temperature, but it did not make any progress until it was removed to the greenhouse, when it began to flourish at once.

It may be remarked here, that in raising Ferns from spores, if it can be managed it is best to remove the pans to a house where there are no specimens, as, if it is a scarce Fern difficult to raise, numerous spores from common kinds will find their way into the pan. To prevent this in a measure, a square of glass neatly fitting over the top is desirable.—J. Douglas.

POTATOES—DISEASE—MERITS.

A great deal has appeared in the Journal lately on the subject of this favourite esculent, and if I take off my coat to enter the arena it is not that, like Paddy, I would trail it along the ground and ask, "Is there any jintleman that would like to tread on it?" for I do not feel at all inclined to dispute. I have nothing to do with the subject of cultivation; so much has been said by so many of your correspondents—and well said—that it leaves little for anyone else to say; and I know that in the case of some, such as Mr. Sage, their theory is borne out by their practice, for a more perfect example of Potato-growing I never saw than with him when he was at Sir Edward Dering's at Surrenden, where, indeed, under difficult circumstances he displayed in all departments of his garden the skill of an adept. There is one point in connection with Potatoes which I would like to say a word about, and that is the subject of the disease.

I am more than ever persuaded that this is a mystery totally unsolved, as great a mystery as it was in the days when it first made its appearance. Let me take the past season as an example. I rather astonished some good horticulturists from various parts the other day, when I stated that I had never had the Potato disease so badly in my garden as last year. "Disease! What, last year! Why, we have not seen a diseased root!" Yet so it was. A few miles off the Potatoes were perfectly free from disease, although small, but all around me they were bad. Some of the cottagers here had not one good Potato in five; they grew out—supertuberated as it is now called—grew away like wildfire, but the produce was very disappointing. "Perhaps you too highly manured," says one. Well, one place where I grew mine was a portion of a meadow which had not been turned up for twenty years and had not a spoonful of manure put upon it, so that will not hold. "Ah! but," whispers my friend Mr. Radclyffe, "you did not dig up early enough." Well, I dug up some Lapstones early in August and others early in September, and there was no difference. "But perhaps you grew only delicate kinds." Wrong again. I grew thirty-six different varieties, a thing I am not likely to do again, and one thing only I have found—that the coarser the Potato the less liable it seems to be to be attacked. But this again varies in other places, for I remember seeing this year some of the very coarsest red Potatoes grown (called March Reds here), as badly diseased as any, so that I believe the Potato disease to be one of those things "no fellow can understand." That it is dependant somehow on atmospheric influence cannot be denied, and that the first week of August seems to be about the time of its commencement is also undeniable. I have never but once seen early Potatoes suffer from it, and if by early planting the crop could be ripened off by the beginning of August I expect the tubers would be pretty safe. This is Mr. Radclyffe's plan, and I believe it answers with him.

With regard to what constitutes a good Potato I have very decided and perhaps hypercritical notions, but unless we have a good standard we shall be inundated, as we already are, with rubbish. These qualities come, I think, in the order named—1, Flavour; 2, Texture; 3, Colour; 4, Form. With regard to flavour, there are some people who discern no difference. A Potato is a Potato, and that is all; it may be earthy or not, mealy or waxy, it is nothing to them. Now to this I cannot subscribe. So necessary an article of food ought to be as good as we can get it. It is as useful as bread, and we ought to be as careful to have good Potatoes as good bread. If a Potato is earthy and strong I think all its other good qualities avail it nothing. And here let me protest against a statement made some time since in a contemporary, that it was a mistake to boil Potatoes in their skins, that they always had an earthy taste. Now, I would never boil a Potato, they ought either to be steamed or baked. To boil Potatoes peeled is to boil all flavour out of them; and well do I remember Power, the inimitable Irish actor, describing his visit to England, saying, "Them's a barbarian people, they peels their taters afore they biles them." A Potato should not be sweet, but should have a peculiarly delicate flavour unlike any other vegetable one can name. As to texture, mealiness is an essential to a good Potato, but this, withal, not of too decided a character; there ought to be firmness as well—no medium. Mr. Fenn's Onwards is too floury, and I believe when that is the case flavour suffers; but this is a much rarer defect than the opposite, closeness. Some people prefer a waxy Potato, and there is no accounting for taste, but I think no true judge of the esculent will agree with this perverted judgment. Colour, of course, is not so material a point as the others, but a Potato ought neither to be yellow nor red; when it is yellow there is generally a tendency to waxiness, and when red to coarseness. A Potato ought always to be white inside. As regards form, my own preference goes decidedly in every respect for the kidney or pebble-shaped Potato, although some prefer round ones. But whichever they are they ought to be shapely, the eyes not sunk deeply, and of medium size. I quite agree with my friend Mr. Radclyffe that middle-sized tubers are the best; even the very best kinds when overgrown are not so good as when smaller.

Having thus laid down what in my opinion are the points to be considered in a Potato, I proceed to examine those which have come under my notice. The soils in which I have grown them are a pasture whence the top spit was taken in the spring, and my garden, which is of a good blackish loam, such as is generally called good garden soil. In giving my opinion of the sorts grown by me I mean simply to speak of them as I found them. I know soil and situation have a vast influence on the Potato, and my judgments may not square with those of growers in other localities.

First with regard to the American varieties. Of these I grew Early Rose, Early Goodrich, King of the Earlies or 50-Dollar Potato (what fools there are in the world!) Prolific, and Climax. These are all from one raiser, and all of the same stamp.

Early Rose I grew on a warm bank, in light garden soil, and I found it a well-flavoured Potato. Some grown in another place were very indifferent, and I very much question whether in any ordinary season it will be good. With regard to all the others, I think them essentially bad. They are no doubt good croppers, and where pigs are kept this may be an advantage; but as to flavour they have none, except a nasty one. Their colour is bad, their texture close, and their form large and coarse. I may add that through the kindness of one of our great London seedsmen, to whom I mentioned my opinion of them, and who somewhat questioned its truthfulness, I was enabled to cook a dish of each of these varieties as imported from America, so that I was able to give them a fair trial; and of the things to eat, drink, and avoid, I should place in the latter category these American Potatoes. I do not see one redeeming feature in them, and did I not know what varying opinions and tastes there are in the world I should most heartily wonder at their being ever sold. "*Omne ignotum pro magnifico*" may be true of them before trial. They come from a long way off, and the Americans may have different notions on these subjects—in fact they must have. Mr. W. Robinson exhibited on January 18th some of the favourite Potatoes of the Mormons, and they were hardly distinguishable from Bovinia, so fit only for pigs; but that anyone having once grown them should wish to again try his hand at them surpasses my belief. If this be American taste we are in the matter of Potatoes far ahead of them.

My opinion of the English varieties I must postpone.—D., *Deal.*

POINSETTIA PULCHERRIMA CULTURE.

So much has been said about the cultivation of this plant that to some it will appear superfluous to say any more; however, the fact of its being one of the very best plants for conservatory and house decoration in winter, and the hope that my experience in its cultivation may induce others to grow it more largely, must be my excuse for these few remarks.

I have in our conservatory just now about one hundred plants from 6 to 12 inches high, many with bracts 10 inches across. Your readers can imagine much better than I can describe the effect such a display will have amongst a collection of miscellaneous decorative plants.

My practice is, when the plants have done blooming to put them all together in the corner of a light pit, the temperature of which is intermediate, giving them only just enough water to keep their roots alive—much the same as one would treat a

pot Vine at rest in winter. My oldest plants are but two years old; all these I throw away, keeping only those struck last year for growing on another season, and to propagate from, because I consider the summer-struck plants by far the most effective.

When the plants begin to move, which will not be before the beginning of April if kept as mentioned before, they should be cut back to three eyes; and those who have not a sufficient stock can easily increase it by inserting the eyes in shallow pans or small pots, and growing them in a genial heat throughout the summer; but they do not make such good plants as cuttings. After being cut down, the plants should be syringed once or twice a-day according to the weather, kept close, and in the course of a week or ten days should have a thorough watering with tepid water. When they have fairly started into growth turn them out of their pots, shake the old soil entirely out, and with a sharp knife cut their roots well back. Repot, not too firmly, in clean pots, and as small as you conveniently can, using a compost of two parts turfy loam, one of peat, and one of rotten cow dung, with a liberal admixture of silver sand. After potting return the plants to the same pit; or a more shady situation would suit them better for about a fortnight, or until they have again started into growth, because if they are allowed to flag for any length of time at this stage, through negligence or any other cause, it will be very injurious to them. When they have overcome the effect of their potting, put them back in a light pit, and keep them close to the glass. Give air freely in the morning, plenty of water, and as much room as you can afford them. Close the pit early in the afternoon, having previously syringed walls, pipes, and all other available spaces. When the plants have filled their pots with roots shift into a larger size, and treat as before recommended.

At the beginning of August (not later), after the plants have again filled their pots with roots, have in readiness, if possible, a dung frame with a genial sweet heat. Take off the cuttings with four or five large leaves attached, insert each cutting singly in a 3-inch pot without removing a leaf from the shoot, and keep them close for about ten days or a fortnight (take care there is no rank heat in the frame), and they will be struck. When they have filled their small pots with roots, which will be very soon, pot and treat as recommended for the others, until the bracts appear, when they will do better in an ordinary stove, watering them two or three times a-week with weak guano water.

Anyone who will faithfully follow the practice I have endeavoured to describe, cannot, I am sure, fail of success.—C. Thomas, *Drayton Manor Gardens.*

CALCEOLARIAS, THEIR CULTURE AND FAILURES.

Mr. Record having at page 44 directed attention to the behaviour of the Calceolaria during the past summer, I am inclined to endorse much that he has said on the matter, and to give my reasons for differing from him as regards some of the details. First of all I have not had so much experience as many with what is very properly called "disease" in these plants; although in certain seasons they have done badly, but seldom have any died off in that sudden manner of which others complain, after the plant has attained a good size and shown every indication of good health. On more than one occasion, however, there has been so destructive an attack of aphis just before the plants were turned out, that they never recovered it. At another time circumstances have prevented our attending to them in time, and they have stood too long in the cutting bed and become drawn up and been otherwise injured; both these evils I admit are capable of amendment, but at a very busy time it is not always possible to prevent something being neglected, and on more than one occasion the two evils alluded to have marred our Calceolaria bloom considerably. The difficulty of ensuring them the attention they require has induced me on more than one occasion to treat them with what I may justly call undue harshness, rather than allow them to spoil each other by the stifling indulgence of remaining in the cutting bed; in other words, I have tried planting them out long before the period generally thought proper, and with a result that will be described. As the mode in which they are wintered, and other circumstances, have considerable influence on their condition at planting-out time, I will commence with their propagation.

Adjoining one of the walks in the kitchen garden, running east and west, are two brick pits, each 120 feet long, and rather less than 6 feet wide inside, the brickwork 4½ inches thick, and with a timber wall plate back and front, and the height above ground is a little less than 18 inches in front, and something more than that at back; but the inequality of the ground makes the actual difference between the back and front about 18 inches. There are no rafters proper, but the back and front walls are tied together by cross pieces of timber set flush with them, and 10 or 12 feet apart, and there are a few brick partitions dividing the pit into compartments. The whole is as simple and inexpensive a pit as could well be imagined. The absence of rafters allows of our digging, and of putting in cuttings, more conveniently than if they were there, while any width of light or shutters will fit if long enough to take a bearing on each side. In one of these pits adjoining the vegetable quarter of the kitchen garden I have for many years been in the habit of wintering Calceolarias, and none of our bedding kinds, excepting, perhaps, a new or choice one, has had a place in a pot, pan, or box for at least eighteen years, and their treatment has been the reverse of coddling, yet I am constrained to say that in general they do not flower so well out of doors as they did at the commencement of that period; but as this, in my case at least, is owing to causes in no way connected with their treatment in winter, I may as well, when stating the character of the cold pit, describe the mode in which they are treated there.

As allusion has been frequently made to the time of putting in the cuttings, I may remark that I do not think the mere fact of their being put in, say at the beginning of October or end of November, is always the cause of their doing well or badly, for I have put them in as late as Christmas and as early as the end of September. In general, however, the condition of the weather and the character of the cuttings point out the time for propagating; as a rule, before doing so, it is better to let the dry weather, which sometimes continues for a week or more into October, be fairly over and moist weather fairly set in. Do not wait until severe frosts have injured the plants, not but that they will bear a little frost; still it is better not to be too late. In general the most of our cuttings are put in during October; but as we rarely put the lights on for a long time afterwards, there is no inducement to hasten their rooting, and sometimes their appearance, if a dry, withering wind occur, is not inviting; on the approach of frost, however, they are covered up with such odd lights as there are to spare, and, if these be not sufficient, with wooden shutters made of half-inch boards. At the commencement of the late severe weather, happening to have as many old lights as covered all the Calceolarias, and some shutters to spare, the latter were laid over a portion of the glass on December 20th, and remained there till January 21st, the Calceolarias being thirty-two days in darkness, and by their appearance I do not expect to lose any, except some plants of C. amplexicaulis; even where there was glass only, the Calceolarias seem to have survived. A covering of snow during the most severe period was of much service, and a little snow was also thrown against the brick walls forming the sides, and as they were not uncovered until nearly ten days after a thaw had set in, the evils of a sudden change of temperature were avoided.

Calceolarias will endure moisture and confinement to a degree which few other plants of similar growth will resist; nevertheless, for some years I have been in the habit of putting in the same pit Gazanias, Cupheas, Cineraria maritima, and other plants, and with a fair share of success; rows of these between different kinds of Calceolarias look very well at the present time, January 23rd. I have never been able to do much with Verbenas, and Centaurea candidissima has not always succeeded well, although C. gymnocarpa usually does. As the character of the Calceolaria cuttings has been alluded to by Mr. Record, I may say that if I had the choice I would prefer short-jointed, rather stubby cuttings slipped, not cut off, with the ragged heel, which I would leave on, taking off only one, or at most two leaves; but as the character of the season determines the kind of cutting, it is not always that a choice can be made. Usually when Calceolarias have been arrested in their growth, say in the middle of July, by the dry weather, they flower out whatever shoots they have, and grow no more, or very little, until the moist weather of September or later again starts them into growth, when a rapid long-jointed growth often takes place, so that as a matter of necessity the cuttings must be shortened, as was the case with the bulk of those here the past season. Of course a less robust growth is met with when plants have been occupying some indifferent position; but the propensity of the plant to furnish roots in winter is so great,

that whatever the kind of cuttings, most of them root pretty freely; succulent long-jointed shoots, with hollow stems, seem to stiffen after being inserted in the ground, and eventually furnish stocky plants.

Our mode of putting in the cuttings is to level and dig the ground in the pit, and add as much roadside or drift sand as seems necessary to make the soil open; but before that, if it should happen that the same place has had a heavy crop of Calceolarias upon it the preceding season, the soil is thrown out upon the kitchen-garden side, and as much taken from thence as will replace it, the exchange being equally beneficial to kitchen-garden crops. Of course all stones of large size are kept out, and the ground for the Calceolarias is not dug more than 6 inches deep. Sufficient sand having been added, and a board for the workman to stand on, he inserts the cuttings in rows, as nearly 3 inches apart as possible, and certainly not more than 2 inches from each other in the row; this gives twenty-four to every square foot, and I think there are sometimes more than that. The cuttings remain till, probably, the beginning of March, when they will be well rooted, and alternate rows are lifted out by a sharp spade being thrust in on each side of them. These rows are bedded out in some sheltered place in suitable soil, and the places they occupied are filled up with fresh soil, so that the plants which remain have more room to grow. I very seldom stop them, except in the case of some that are not likely to have a chance of being planted out soon, in which case stopping may be practised; but where there is a choice it is better to plant out first those which have not been disturbed at all, as they will be the most forward, and when this can be done, and the rudest of all shelter is afforded them for a little time, it will generally be found better than waiting later. Last year we planted out upwards of three thousand Calceolarias before April 15th, and they did better than those that were later, although they had no assistance nor protection; fortunately there were no frosts till they had been more than a week out, and the weather was favourable at the time of planting. I have also in former years planted out sooner than this, but it was merely as an experiment, and in general the end of April is early enough; at the same time, planting out so that the plants may have the benefit of a gentle shower is of more importance to the Calceolaria than to most bedders, and where they are choking each other in the cutting bed delay only increases the evil, and renders them more and more unable to make that effort to grow so much needed by a plant that has to be removed. Of course all coverings are dispensed with late in the season, and, in fact, as soon as the plants show a determination to rush upwards full exposure must be given, and only on frosty nights are the coverings put on; at other times they lie heaped one above another over some vacant place in the pit, or if compelled to be above plants, their position is changed as often as is required.

Of the causes which tend to this plant failing, as it often does, much has been written, and certainly there is yet much to learn. It would be a boon to flower gardening if anyone could make the cultivation of the Calceolaria as easy a matter as it was twenty years ago; at the same time the treatment ought to be very simple, easy of application, and suited to other plants which are often made to occupy the same bed as the Calceolaria; for a soil specially adapted to this plant, and that will not also do for many others, is next to useless in a great many cases, as some of our most important flower beds contain three or four species of plants, and it is very inconvenient, often impossible, to treat one of them differently from the rest.

I have little hope of much success in the way above indicated; I have certainly more faith in a judicious selection of varieties suited to the soil and situation, and I believe some good would result from going back to the first imported species if it is to be had, for I am not sure that the long narrow-leaved kind often called angustifolia now, is really the original one of that name, neither may the short rugose-leaved kind be true. One of the first of the named varieties was certainly the best I had the past summer, and next to it was one popular about twenty-five years ago—viz., C. viscossima, while C. Aurea floribunda failed very much; although I must own that in some seasons this variety has done well, still I think it is about worn out. My practice of late has been to plant two kinds together, and if in a row, alternate plants of a broad and narrow-leaved variety, so that in the event of one failing the other may succeed. In general the dwarfest varieties succeed worst; they seem to make least progress in growth, and now and then some die off after lingering for a time in a half-dead condition; for, as I have said before, it is seldom any go off suddenly with us (except in the case of the so-called disease), if they once show signs of good health.

With regard to the character of soil best adapted for the Calceolaria, I am far from being certain that the views I now venture to put forth are correct, but I should say that the plant would seem to enjoy a soil in which lime is plentiful, but to add it to some fertile soils might be very imprudent, on account of its destroying the organic matter, so that I hardly expect to see Calceolarias do well in the places where Golden Geraniums are grown to great perfection. Many years ago I noticed this in some gardens in Staffordshire and elsewhere, about the time that Golden Chain Geranium was first introduced in quantity; the Calceolarias were anything but creditable, and, I believe, have become worse since. I should say the absence of lime had something to do with the one plant doing so well, and the other so badly. Of course, season has an influence, but the Calceolaria is rather a gross feeder, liking heat, depth of soil, and moisture, and when the latter is absent success is precarious. In my own case the plants generally flower well early in the season—in fact, flower themselves out, no growth taking place owing to the dryness of the early summer, and when rain in sufficient quantity does come, a quick growth is the result, but it is then too late to flower, consequently after the second week in August, or so, Calceolaria bloom is far from plentiful. Watering by hand, whether beneficial or not (for I have my doubts about it), is out of the question with us, and even if it were of service, water could not be applied to Calceolarias growing by the side of Geraniums without the latter having it also, and probably becoming overluxuriant.

I should be glad to fall in with some plan by which the constant flowering of this plant could be insured without that special management, which, if not equivalent to its prohibition, is certainly very inconvenient. At the same time we cannot well do without it. No other substitute yet proposed is likely to be so great a favourite; and if varieties of better constitution are not to be had, would it not be worth while to re-introduce the plant from its native mountains? and if its re-appearance gave us a few years of its services, as at first, the expense of importing it afresh might not be thrown away. Some years ago I had cuttings from a place one hundred miles off to try what a change would effect, but that was not like introducing the original plant.

From the above, it will be seen that I attribute the failures we have had here with this plant to the dryness of the season alone, and I imagine that the plant will succeed in places where rain during the early summer months is more plentiful than it usually is with us, provided the soil and other circumstances are favourable. Heat, I also believe, is an essential condition, and it is possibly the deficiency of heat which makes the plant more unwilling to grow near the coast, but control over the seasons is out of the question. The habit of the plant, the brilliancy of colour which its flowers present, and other qualities, make the Calceolaria a plant which we cannot do without, and I hope to see that uncertainty which at present hangs over it removed, and the good service that it did in the flower garden twenty years ago resumed. Some good, no doubt, may be done by those who have been hitherto successful with it reporting the character of the soil and other particulars, but I fear those who have had cause to complain of it form the majority.—J. Robson.

PORTRAIT OF MR. RIVERS.

In addition to subscriptions already announced, the following have been received:—

Coleman, Mr. J. N., Great Mongeham, Deal....	0	5	0
Kemp, Rev. George, Sevenoaks	1	1	0

ROYAL HORTICULTURAL SOCIETY'S SCHEDULE.

There can be no question as to the very varied character of the prizes offered in connection with the Society's exhibitions this year, and it will not be from want of encouragement if any cultivator in any branch of horticulture do not see something of his favourite hobby this year, while the Show at Nottingham, with its £1000 of prizes, ought to be a great success. There are some features in the new schedule which especially call for remark, particularly that of different nurserymen offering prizes for the productions they have been the means of introducing amongst us. Mr. W. Paul offers prizes for

Princess Christian Rose, and Messrs. Carter & Co. for vegetables. I think that such a course deserves the highest praise, and that were it to be imitated by other introducers of novelties we should be better able to test the value of the very many varieties of new vegetables, and, what is more, to see how many different vegetables are out under the same name—not, I believe, dishonestly so, but simply because there is no way of comparing them.

I am sorry to see Hyacinths so poorly encouraged, and cannot but think the prize for eighteen white Hyacinths a great mistake.—D., *Deal*.

GROUND LEVELLING AND PRACTICAL GARDEN PLOTTING.—No. 12.

DRAWING PLANS.

To draw and transfer *fig.* 35 to the ground, form the rectangle A E C D. Draw the diameter lines E F and G H, and the other lines as 1 2, 3 4, &c. Lines 7 8, 17 18, 33 34, 43 44, form the square *i k m n*; on each side of the diameter lines E F and G H point off 2 feet, and draw lines 11 12, 13 14, 37 38, 39 40; draw the diagonal lines *i n*, *m k*; draw squares *a b c d* and *e f g h* on the diagonal lines.

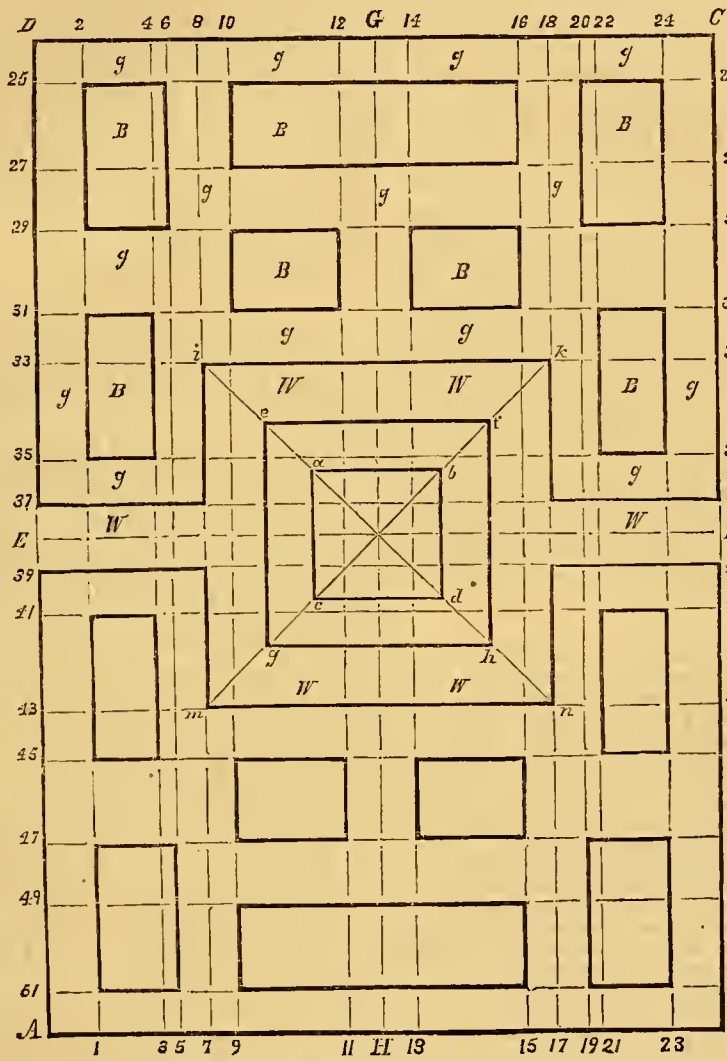

Fig. 35. Scale 12 feet to the inch.

To transfer the plan to the ground, insert a stake at point A, and lay a line from point A to point B, which is 42 feet 6 inches in length; insert a stake at point B; lay the line from point B to point C, the distance between being 63 feet; insert a stake at point C; lay the line to point D, and there insert a stake. Line C D is equal to line A B. Lay the line from D to A, which is equal to line B C. Lay the diameter lines E F and G H. From the stake at point A, on line A B, measure 3 feet (which is the width of the grass verge), and insert a peg as at point 1. From the stake at point D find the corresponding point 2. From the stake at point A measure 7 feet, and insert a peg as at point 3; find the corresponding point 4 on line D C, and there insert a peg. From the peg at point A, on line A B, measure 8 feet 3 inches, and insert a peg as at point 5; also on line D C find the corresponding point 6, and there insert a peg. Again from the stake at point A measure 10 feet, and insert a peg as at point 7; on line D C find the corresponding point 8, and insert a peg. From stake A measure 12 feet, and insert a peg as at point 9; find the corresponding point 10 on line D C, and insert a peg. On each side of the diameter lines E F and G H measure 2 feet, and insert pegs as at points 11 12, 13 14, 37 38, 39 and 40. Points 15, 17, 19, 21 and 23 are found from the stake at point B as points 1, 3, 5, 7, and 9 are found from the stake at point A. From the stake at point C find the corresponding points 16, 18, 20, 22, and 24; insert a peg at each point. From the stake at point A, on line A D, measure 3 feet, and insert a peg as at point 51. On the same line measure 8 feet, and insert a peg as at point 49; also from the same point measure 12 feet, and insert a peg as at point 47; on the same line measure 17 feet 3 inches, and insert a peg as at point 45; from the peg at point A measure 20 feet, and insert a peg as at point 43; from the same stake measure 26 feet 3 inches, and insert a peg as at point 41. Find the corresponding points on line B C, as points 52, 50, 48, 46, 44, and 42. From the stake at point D, on line D A, find points 25, 27, 29, 31, 33, and 35 in the same manner as points 51, &c., from the stake at point A. From the stake at point C, on line C B, find the corresponding points 26, 28, 30, 32, 34, and 36, and insert a peg at each point. Lay lines as from peg 1 to peg 2, and from peg 3 to peg 4, and so on, until lines are laid between all the corresponding pegs. Lines 7 8, 17 18 33 34, 43 and 44 form the square *i k m n*. Lay the diagonal lines *m k* and *i n*. On the diagonal lines form square *a b c d*, which is intended for a bed, the length of the side being 8 feet. Form square *e f g h*, the side being 14 feet. The space between the two squares is intended for a grass verge 3 feet wide; insert a peg at each point, and lay lines from peg to peg, and the figure is complete. B, beds; *g*, grass; w, walk.—M. O'Donnell, *Gardener to E. Leeming, Esq., Spring Grove, Richmond.*

POTATOES—PLANTING EARLY, DETECTING QUALITY, AND OTHER HINTS.

The "noble tuber!" I regret to say that I hear a bad account of the state of Potatoes, by reason of the severe frosts. The poor people here have lost both their "eating" and seed Potatoes. This winter has been the severest since 1860. Notwithstanding thick coverings of straw, I have lost a bushel and a half. As soon as the frost broke up I commenced planting on January 14th, and have just finished all my garden plots. The ground worked well; with the aid of a little straw placed

over the ground, I look for no more disaster from frost. A little surface frost excludes the air, and helps, with the straw, to preserve the "noble tuber." Last year severe frosts succeeded the planting, but no mischief was done to the planted tubers. Some of the plots were not even covered with straw, but were fully exposed to the east, south-west, and north winds, in this very exposed vale.

It is said that if frosted Potatoes are placed in water for a few days, and then dried before the fire, they will "do" for seed. I have five tubers in water, and intend to plant them for experiment. I should hardly think they would succeed. A frosted Potato is decomposed.

I believe the Potato disease, in a great measure, partakes of the nature of dropsy, as it usually takes place after heavy rains succeeding long drought. Perhaps what we call fungus is the mere disruption of the cells. I merely throw out the suggestion, and confess that I am quite in the dark. I have had no diseased Potatoes this year, and only one diseased tuber last year. I am satisfied that "early ripeners and late keepers" are the only sorts to plant.

I am much amused by reading what is said of some Potatoes, which I was obliged to cast out. It is not my province to write them down. The sorts I keep are well known, and need not be named. The following observations may interest, and, perhaps, profit the reader.

If you buy a sack of Potatoes, buy big and moderate-sized ones together, and you will obtain 20 lbs. more weight than by buying all large ones. Moreover, large Potatoes, even if the sort is good, are not so eatable as moderate-sized Potatoes. If you want to test uncooked Potatoes, take, say, five sorts or more of the same size, and whichever weighs heaviest will be the best Potato when cooked. A light Potato never yet was good. When Potatoes are cooked, if you do not wish to taste them, you can tell their quality by breaking them in half, and applying a magnifying glass. That will be the best Potato, the grains of which look whitest, like pounded white sugar. If the grains look dark or muddy, the Potato will not be good. A cat or dog will not eat a Potato unless it is good; their fine noses detect what our unassisted eyes cannot see or noses smell. My latest, Yorkshire Hero and Taylor's Yorkshire Hybrid, are good, and will last well till June. Last year my servants preferred them to the Royal Ashleaf, dug June 4th. Plant your Potatoes before they are much grown out. Breaking off the sprouts weakens the plant.—W. F. Radclyffe.

SETTING AND CROSSING GRAPES.

As Mr. Pearson remarks at page 509 of last volume, we have all seen recommended for the abovenamed practices, by one a hot dry atmosphere, by another a damp atmosphere, and by a third a high dry temperature with plenty of air. From my experience I am decidedly of opinion that either extreme is not to be commended. Like Mr. Pearson I have been crossing Grapes for the last twelve years, and many other things for the last twenty, and have taken much interest in the pursuit. I have always found a dry air not productive of pollen.

With the view of hearing the opinion of others, about two years ago I put the question to the gardening public whether a dry or a damp atmosphere was considered the more favourable for setting. I consider no decided treatment can be laid down as ensuring the desired result, especially in a mixed collection including such known bad setters as those named by Mr. Pearson—Black Morocco and Canon Hall Muscat. These two sorts I have grown successfully under the following treatment.

The Black Morocco I found always had on the top of every pistil a dewdrop. I considered this prevented fertilisation by not allowing the pollen a free entrance at the top of the pistil. I applied the pollen of free setters, but finding this ineffectual, twice a-day, as the bunches came into bloom, I carefully drew them through my hand till I was certain the dewdrops were all cleared off. Mr. Pearson's mode of proceeding had the same effect, for he brushed the bunches with a large camel's-hair brush covered with pollen; in doing this he would clear away the dewdrops, and a portion of pollen would at the same time be applied.

As to the Canon Hall Muscat I had to grow a number of it, our family having a great liking for large-berried Grapes, and I tried several experiments with this variety. I carefully applied pollen of free-setting sorts, but that I found not effectual. Anyone who has grown the Canon Hall must have noticed that there is double the number of flower-pips on every bunch as compared with other Grapes. This I thought was approaching to a monstrosity, therefore I waited till the bunch was about to bloom, and then severely thinned the flower-pips, taking away three out of every four. Under this treatment, and by tapping gently the rods when in bloom, I rarely failed to have satisfactory-set bunches.

As regards crossing, I agree with Mr. Pearson that it is not so easy to effectually cross Grapes as many would imagine. I agree with Mr. Pearson also that colour, according to my experience, is accidental, as I have proved in the three last varieties I operated on. These were all dark varieties. The first I shall notice is my own Champion Hamburgh Muscat, sent out by Messrs. Veitch. This I crossed with Snow's Black Muscat Hamburgh [Black Muscat of Alexandria]; the produce was a Golden Champion Hamburgh with a true Muscat flavour, and it showed colour before the common Hamburgh in the same house. The second was Lady Downe's crossed with Snow's Black Muscat Hamburgh; the produce was a deep golden-coloured Grape of the same habit of bunch as the male parent, the bunch long and well-shouldered, the berries with a distinct Muscat flavour. The third was Snow's Black Muscat Hamburgh crossed with Muscat of Alexandria; the produce was a deep golden-coloured Grape, with the bunch the same in habit as Snow's Black Muscat Hamburgh; the bunch long, well shouldered, setting freely, and perfuming the house, and the flavour a decided perfumed Muscat. The golden colour comes much sooner than in a Muscat of Alexandria.—W. Melville, *St. Lawrence Vineries, Jersey.*

P.S.—There have been erected here nearly 1000 feet of new glass, of which at some future time I may give details.—W. M.

FRUIT TREES FOR SMALL GARDENS.

"C. C. E." asks me, page 432, vol. xix., to say "whether my conclusions have been arrived at by actual experiment with a strict cash account, or whether they are merely an inference, &c.?"

The conclusions are based on actual experiment, but not with a strict cash account, for we in private gardens do not keep (to our disgrace be it said), cash accounts in the way that "C. C. E." means. We grow what our employers regard as luxuries more than as paying crops, and I fear "C. C. E.," and also our Editors, see fruit as do our employers; the finest and best is all they care for, having no eye themselves to the cash account. There is a great difference between growing for private use and for sale. For instance: A has a vinery erected for growing Grapes for his own use, and B has one constructed to grow them for sale. A spends fully twice as much on the house as B, and he plants kinds that he has a peculiar liking for—kinds that will not give half the produce of those B plants. A wants variety, and the gratification of his palate; but B wants cash, and he must plant certain heavy croppers, and of a quality most in demand. B's house pays, with a large margin of profit, but A's does not pay with a strict cash account. It is just the same with bush-fruit trees. A will have the kinds calculated to afford the finest desserts, he thinks nothing of a kind that is a certain cropper, and in quality little inferior to that which he must have at any cost; he "goes in" for the very best of everything, likes a fruit because it has a peculiar flavour, and forgets, perhaps, that it is a notoriously shy bearer, but he likes it all the better for that reason, and wisely keeps from asking a strict cash account of his gardener. His gardener (B we will call him), commences growing for sale. He does not cater for those who may be purchasers of fruits for the sake of their peculiar flavour, but he plants the good and useful kinds, which always find a ready sale, and are large, certain croppers. He finds, for instance, that Lord Suffield, Cox's Pomona, Cox's Orange Pippin, and Domelow's Seedling Apples will at three years old give a peck of fine and equally good fruit for his purpose, while the fancy sorts do not at that age give a tenth of the quantity. I need not tell "C. C. E.," that an acre planted to suit A will not pay, for that is, I believe, his case; "a source of increasing interest and pleasure" it may be, but he must not look for the cent. per cent. return of B at seven years, which I know from actual experience cannot fail to result if the trees bear as well by the hundred as by the dozen, and by the thousand as by the hundred.

I am glad of "C. C. E.'s" communication, for it gives me an opportunity of saying something of kinds I would grow for market. "What! Not all named in your list?" Why, no? These varieties will suit all but the very fastidious, being most excellent in all respects; but for sale I should grow of kitchen

Apples: Lord Suffield, Cox's Pomona, Dumelow's Seedling, Gooseberry Apple. Dessert Apples: Early Harvest (a few), Cox's Orange Pippin, and Pitmaston Nonpareil. *Plums:* Oullins Golden, Early Rivers, Orleans, Prince Englebert, July Green Gage, Belgian Purple, and Victoria. *Pears* · Bon Chrêtien, Beurré Bachelier, Beurré Diel, Beurré Hardy, Bergamotte Esperen, Beurré d'Amanlis, Comte de Lamy, Alexandre Lambré, and Marie Louise. Will "C. C. E.," or any one, state what results they have found from the above sorts, by actual experiment by the acre?

Again, "C. C. E." says I have a large margin in the estimated cost of trees—Apples at 1*s.* 6*d.* each. He quotes prices which were I to buy trees at, I should not plant them at 6 feet apart, but in lines 3 feet from each other, with a distance of 18 inches in the row, and I would keep the trees there until they were fully 4 feet high, well furnished, and fit for planting at 6 feet apart, which I do not consider they are until they have had three years' growth and training beyond the maiden growth. The trees would cost, if they were selected at any nursery, what I have named, for I would, of course, take only the best, such as I should not have to keep unprofitably, but that would go to work at once. I am no believer in cheap first costs, and should go in for trees for an acre as for a select border—varieties excepted. Thus "C. C. E.'s" trees at seven years would only be doing what mine would at four.—G. Abbey.

ANONYMOUS CRITICISM—MESSRS. CARTER'S PRIZES.

In an able article on criticism which has arrested my attention, Mr. Paul lays bare an unjust practice, and makes out a good case for publicity of critics' names. It will have its effect. A few years ago the country was flooded by lucifer matchboxes, on which were engraved some well-remembered figures. Look at them on one side, and we see the very acme of pleasure and satisfaction beaming from the countenances of the faces there depicted; stand on the other side of the box, and we see the same figures expressing the very incarnation of ugliness. Criticism has two sides. Mr. Paul stands on one side—publicity, and sees the pleasant aspect. I stand on the other side, and see the same figure ugly—inexpressibly ugly. If I go to Mr. Paul's side I shall see as he sees. If Mr. Paul will come to my side he will see as I see. I have gone over to Mr. Paul's side, have seen with him, and believe. Let him come over to my side, and believe with me, if he can. If Mr. Paul can see as I see, and feel as I feel, he will, I think, say as I say, that if anonymous criticism is ugly, the other side of the question is ugly too.

Mr. Paul has given an example. I will give one. I have in times past sometimes felt it a duty or a pleasure to contribute an article to this and other papers, and to which I have attached my name and address. On almost every occasion I have had private letters bothering me for something or other. Now, I do not call this ugly, but I do not call it nice, as it raises the question courtesy *versus* postage stamps. Through unavoidable circumstances I am often scarce of the latter, and I do not grumble much; but if conserving the former adds to the existing scarcity of the latter, I have a right to grumble and stop the demand on my resources. This, as before said, I do not call ugly, but I do the following. If I have happened to have written recommendatory of an article, and have given the reason of my success, I have been insulted by applications for a few dozens or a few hundreds, intimating that as the production cost me nothing, I might make a "good thing of it," and my master be no worse. I call that the ugly side of publicity, and I determined to avoid the temptation by taking away the means which called it into action. Seldom since, except by special request, have I appended my name, whether the article has contained praise or blame, or whether in this respect it has been neutral. Herein I may have erred, not that anything I could say would do either much good or much harm, but that it is but just and honest in principle that critics in censuring men or things should append their names. This is manifestly so fair that it needs no attempt at proving, and I daresay it is all that Mr. Paul contends for. But while I lay down this rule for my own guide, and act up to it, I shall also act pretty closely to another, and not append my name to anything personally commendatory of one man above another. For instance, were I to bring to public notice some splendid Vines which I can see every day, and of whose parentage Mr. Paul might be proud, and to append my name, that eminent nurseryman might possibly not complain of my doing so, but Mr. Pearson might perhaps question my motives, because the same house contains some from him equally good, but yet unnoticed. Some men's names are of greater strength than their judgment. At present the general rule stands thus—to give one's name when we praise, and to withhold it when we blame. I am aware there are many exceptions, but it seems to be the rule, and in my humble opinion it would be as well for all parties if it were simply reversed.

Having expressed my thoughts, I will leave the subject to clearer heads and abler pens than mine, and venture a word of comment on the schedule of prizes offered through the Royal Horticultural Society by Messrs. Carter & Co., seedsmen, Holborn. Every year something fresh is brought forward, startling in character and price. It is but natural that the growth and maturity of these new-born subjects ushered into the world with everything that can make them attractive are jealously watched by a criticising and discriminating public. It is right that it should be so, but woe be to the proprietor if they found a character for any of their *protégés* on the results achieved in an abnormal season, and which are not upheld under other aspects and other circumstances. It is right that new subjects should be assailed, and have their bad points mercilessly brought forward—if a thing cannot stand the fire of public criticism it will not fulfil the demands of public utility. I have been their assailant, and probably shall be again. But if it is right that faults should be exposed, it is equally right that virtues should be recognised. That many subjects possess virtue there cannot be a doubt, or the experience of the best cultivators and the judgment of the best authorities go for little or nought. Who that has seen the Alpha, Wonder, and Hundredfold Peas grown under favourable circumstances can fail to recognise in them points of merit of sterling quality? while Potatoes, and even salads and Parsley, have left their mark on the horticultural world. If Messrs. Carter reap the reward of their enterprise it is only what they are entitled to, and if the world is benefited who should begrudge it? At any rate, it is clear they have confidence in the strength of their introductions, or they would not have deliberately adopted such effectual means of exposing their weakness as to offer nearly £50 for the bringing together of their productions and submitting them to the examination of the most competent judges. It is to be hoped the liberal offer will have a liberal response, and those who offer and those who contribute will alike reap a reward from their venture, and general horticulture be collaterally advanced.—W. B. H.

PROGNOSTICATION OF THE PRESENT WINTER.

In last November's number of "Symons's Monthly Meteorological Magazine," Mr. G. D. Brumham, Cirencester, observed that according to a law which for the last hundred years "has *always* proved correct, the coming winter must be remarkably severe—that is, the mean temperature must be very considerably below the average." The law Mr. Brumham stated in the December number of that Magazine is this:—

"When the rainfall of the first seven months of the year is below 10 inches (near London, or at Lyndon in Rutland), or there have been in the first eight months of the year three or more months in each of which the rainfall has been below an inch, the succeeding winter is *always* remarkably severe, if the Greenwich mean temperature of August to October inclusive has been not more than 56°.1 in the former case, or in the latter more than 53°.4."

How the prognostication has been and is being fulfilled we all know, and we have had this note sent us on the subject:—

"I am bound to confess that I have not much faith in weather prophecies in general, so many have been put forth without much foundation to rest upon, have flourished for a time, but soon come to an untimely end, but this, certainly, seems more promising than anything we have seen for a long time, and up to the present period has been remarkably fulfilled, and also has the merit of having been issued before the commencement of the winter, and not in ambiguous language, after the manner of the old-fashioned almanacks by which people might be rendered wise after the event.

"This prophecy, like all others, must stand the test of time, and if found sound will be a valuable acquisition to our meteorological knowledge, and will reflect credit on Mr. Brumham, the discoverer. Whether it continue successful in future years or not I regard it as a step in the right direction, and a line of investigation which should be followed. No doubt the variations of the weather, which appear so strange and unaccountable to us, are not really so, but proceed according to certain fixed

laws, and if we only had a key to them it would be possible to predict the character of the season beforehand with the regularity of a clock; but at present we are far from that happy state of affairs, and are waiting for some meteorological Newton to appear and settle a few of the knotty points for us. Does the moon influence the weather? The French *savants*, after investigating the matter for a long time, came to the conclusion that she did not affect the weather at all. Perhaps it would have been better if they had reported that they could not find out how she affected the weather. The American captains who fetch guano from the South Seas say that the moon does affect the weather, and that there is more rain in certain phases of the moon than in others. Is it not more reasonable to suppose that she does, and that the changes in our atmosphere are caused by the relative position of the sun, moon, and other planets? I think so. It is clear that the tides are affected by the phases of the moon; why not the weather?

"But to return to the prophecy. If the data are sound, no doubt there are reasons which may be shown for their existence. Dryness and low temperature in the early months of the year seem to be the desiderata for cold. Perhaps under these conditions the ice and snow may be less melted in the Arctic regions than at other times. It is certain that in 1868, when there was an unusually warm spring and summer, accompanied with more rain than in 1870, and when the temperature in Iceland in June was as high as it usually is in August, and when ship captains reported that the ice belt round the Pole was driven back further almost than in the memory of man, the warm summer was followed by a very mild winter, and the north-east wind seemed shorn of its usual rigours. Were the previous heat and rain the cause of it? Mr. Brumham, perhaps, would say, Yes; I would rather say, Wait and see if the conclusions arrived at in the table are borne out in future years, and then the investigation of the cause will be likely to add still further to our limited knowledge of the laws of meteorology.—AMATEUR, *Cirencester*."

SOME PREDATORY INSECTS OF OUR GARDENS.—No. 3.

AN entomological friend of mine, whose spite towards gardeners generally is probably to be attributed to the circumstance that in the course of his researches he has come at times into collision with various species of that genus, takes upon him to assert that the majority, large as are their opportunities for observation, have done little towards increasing our stock of facts in natural history. I think, however, that if we look back on the records of the past we shall admit that in matter and in style, what horticulturists do now communicate to our journals from time to time, throws quite into the shade the meagre descriptions which were once thought of value. Still there is scope for improvement, especially amongst working gardeners, and we may hope that, through the impetus given to education by its being regarded as of national importance, natural science and its concomitants will be so taught as not to disgust, but to stimulate the youthful mind, and prepare it for making discoveries on its own account when the after-life gives opportunities. One thing, certainly, caused some difficulty in other days—there were few journals through which facts in natural history could be brought before the public. Some communications came out, however, in the "Gentleman's Magazine," and strange enough they were, for "Sylvanus Urban" was decidedly non-scientific. I quote two amusing specimens of the sort of thing that went down with the reader of a hundred years since. A certain "J. H.," writing an alarmist's letter from Cambridge in 1763, says of insects, that "the embryos of these rapacious animals are now quickening by the rays of the vernal sun. The caterpillars that destroy the trees and hedges glue their nests to the branches. The web is woven with a close texture, and covered with a viscous liquor. In hot weather an effluvium exhales from caterpillars, which is noxious both to man and cattle, and sometimes produces contagious diseases." This is of a general cast; of more particular observations, if such they can be termed, we have such as that written down by "D. J." in 1766. His gardener in digging discovers a mysterious roll. This is opened, master and man both agape with astonishment—behold! a mass of desiccated matter resembling chewed grass, compacted together, 7 inches long, 1 broad, terminating in a blunt end, tenanted by what he calls a single egg, about which the substance was looser. The oddest part of the letter states that a hunt was instituted for the insect which had made it, and the sagacious discoverer could not understand why, after its trouble, it had not waited to see the result! This was probably a nest of some species of solitary bee.

It is possible, however, some may think that in horticulture ignorance regarding the numerous insect pests which mock our labours has some advantages. We reduce the numbers of the enemies we see and can get hold of, but how many are there which work us trouble and yet evade us! Then occasionally there suddenly appears some new blight, and the reflective visage of the gardener, full of insect lore, lengthens as his imagination pictures the divers annoyances it may inflict, which he cannot totally prevent. Increasing knowledge we must increase sorrow, is a reflection, however, that may be pushed too far; in natural history our great danger is a sort of half knowledge, which enables us to talk but gives us little insight. Thus, one who thought himself thoroughly acquainted with caterpillars and their destructive doings, had yet no idea that any were to be found waiting quietly through the winter to recommence their jaw work in spring. It is true of various species in gardens as well as in fields and woods, and an unpleasant lurker of this sort is that producing the Gothic Moth (Mœnia typica). The parent Moths are on the wing often for a couple of months in the summer, coming eagerly enough to an ensnaring sweet compound spread on tree trunks even about London, and in spite of its commonness it deserves to be called handsome. It has been observed by Mr. Newman that the juvenile caterpillars proceed with a certain degree of military regularity, marching in little companies, and confining themselves to the upper surface of the leaves. My own observations confirm this, though, unlike Mr. Newman's specimens, those occurring at the west end of London do not always begin by a short sojourn on trees ere they descend to the lower growth in gardens. I have found eggs and young caterpillars on low plants, nor do they hesitate to devour the produce of the flower as well as that of the kitchen garden. These caterpillars seem to have at all times a partiality for dead leaves—they often hybernate on or amongst them; and, when feeding some in captivity during the spring, I noticed that they ate chiefly at night, hiding under a dried leaf during the day. Hence the species escapes notice in gardens at the very time it is most destructive, and slugs and snails are anathematised occasionally, while the culprit is our Gothic foe, now getting plump, and who would perhaps wink his eyes, if he had any eyelids, to express his satisfaction at the good fare he obtains on the fresh juicy leaves. However, as, by-and-by entering the earth, he becomes a chrysalis, he may chance to get chopped in two by the spade or hoe. From the small proportion of these caterpillars to be found by careful searching in some springs as compared with the number about the preceding autumn, I fancy that they are kept in check by some parasite, or killed by the sharp weather of certain seasons.

Who has not some early associations connected with the Woolly Bear? though this name is applied loosely to various

Chelonia Caja.

hairy caterpillars. I think, however, that it could be demonstrated to be the peculiar property of the common Tiger Moth (Chelonia Caja), the only probable rival being the caterpillar of the White Ermine. An active fellow is the Tiger Caterpillar, though its long silky hairs, as seen at the final change of skin, have nothing resembling wool about them except their light colour on the back. The head and legs are of a deep black. Nor is it remarkable for being bearish in disposition, though it may be thought a feeble miniature of that animal in appearance. An observer, however, reports last year an instance wherein a Tiger Caterpillar proved a cannibal, devouring a chrysalis of a brother; but then there was this excuse, that the individual had been kept on short commons, and, to all

caterpillars, abstinence in warm weather is very trying. It has been questioned whether birds attack hairy caterpillars. No doubt some species do, though others are repelled by this means of defence, especially when the individual attacked has the power, like the present species, of presenting, by rolling into a ring, a surface of hairs in every direction. Were it not for this, as the Tiger Caterpillar feeds conspicuously, its numbers would soon be diminished considerably. As it is, we notice it to be one of the very commonest of caterpillars both in gardens and in uncultivated places, its favourite food-plants in the latter spots being Docks and dead Nettles. Most partial to the kitchen garden, the caterpillar of the Tiger Moth at times turns up on the flower beds, and may even be detected feasting on fruit trees, or disfiguring a choice Pelargonium. One circumstance tending to account for its abundance is the number of eggs deposited by the Moth (stated in some books at 800 or 900; in a case, where I counted what I believe was the whole batch of a female in confinement, the number was about 600), and these are laid in clusters through the sluggishness of the Moths; in fact, they seem rarely to take any extensive flight. The principal business of the young caterpillars during the autumn appears to be the changing of their skins; of these several follow in succession without much increase of size. Ceasing to eat as winter approaches, they retire usually to the roots of the herbage, or, in gardens, to some nook or cranny, there to remain until spring, at whose advent they at once set to work again, but, growing rather slowly, are seldom full fed until June. The cocoon is plentifully besprinkled with the hairs of the caterpillar, which have an unpleasant irritating effect upon the human skin, though this has been questioned, and the effect ascribed to some fluid of a pungent nature ejected by the caterpillar. Certain it is that the Moth when fresh from the chrysalis does possess the power of ejecting, from some apparatus behind the head, an acid liquid which causes smarting. The upper wings, which have given the species its tigrine name, are variable in their marking, as also sometimes the hind wings, usually adorned with blue-black spots on a red ground. An entomologist reared some of the most remarkable types of the darker varieties by feeding the caterpillars on Coltsfoot and Butterbur. Nevertheless, it is the opinion of a moiety of the students of this branch of natural history, that these departures from the normal colouring are results of disease.

Amongst the names of terror in Eastern lands, none are more appalling to the husbandman than that of the Locust. Only three years ago we find that the ravages committed in Algeria by the species were something appalling, though millions of them were slaughtered. The term Locust is applied even in our country in a loose way to various destructive or conspicuous insects, as, for instance, singularly and inappropriately, to the caterpillar of the Death's-head Hawk (Acherontia Atropos), not uncommon at times in the midland counties, an occasional visitant in others. But the question has been often asked with some interest, Does the oriental Locust ever make its way here, and is there any danger of its doing us serious injury? Many specimens of the Orthopterous order had been sent from different places to the Editor of the "Entomologist," who stated that he had doubts whether the true Locust did occur in Britain. Mr. Walker's researches, published in last year's "Entomologist," tend to prove that there are two species, and one of these, the Migratory Locust of South Russia (Pachytylus migratorius), which also occurs in Switzerland, the South of France, and Spain, has occasionally made its way to our shores. There seems to be still some doubt whether this species commits ravages in Syria and Egypt. A number of these were noticed on the coasts of Aberdeenshire, and solitary specimens have been picked up elsewhere. At the discussion which took place at the meeting of the Entomological Society in March last it was asserted that examples of the true African Locust had been taken here, but the nomenclature being confused, the fact is still questionable. In our case I imagine we have little to fear from this species, which, in spite of the long migrations it makes, is peculiarly liable to be affected by atmospheric influences.—J. R. S. C.

NOTES AND GLEANINGS.

According to *Nature* the large conservatory for Orchidaceæ in the Jardin des Plantes at Paris has been destroyed by a Prussian shell. The glass-work was broken, and the plants, which are so delicate, were lost without any hope of recovery. The losses are very serious, as the collection had many valuable specimens obtained from the occupation of Mexico, and from the exertions of the French Scientific Commission, which had been sent to America to explore the empire of the unfortunate Maximilian. M. Chevreuil, the Director of the Museum, has addressed to the Academy of Sciences the following protest:—"The garden of medicinal plants, founded in Paris by an edict of King Louis XIII., dated January 3, 1626, became a Museum of Natural History on the 23rd May, 1794. It was bombarded in the reign of William I., King of Prussia, Count Bismarck being Chancellor, by the Prussian army, on the night of the 8th-9th January 1871. Until then it had been respected by all parties, and by all national and foreign authorities. Paris, January 9, 1871." The Academy has determined that the protest of M. Chevreuil shall be printed at the head of its reports, and the Committee of Professors of the Museum have decided that a marble monument, with an inscription of the protest, shall be placed in one of the galleries of the building, surrounded with projectiles thrown from the enemy's batteries.

—— Amongst the new arrangements made by the Royal Horticultural Society for the present season we have to announce the following:—Mr. Eyles, Superintendent of the Society's garden at South Kensington, retires from that office, and is succeeded by Mr. Barron, who will for the future act as the Society's Garden Superintendent at South Kensington and Chiswick, thus combining the management of the two gardens in one. The position which Mr. Eyles will retain is that of Superintendent of Flower Shows, in conjunction with his profession as a landscape gardener.

—— Messrs. Carter & Co., Seedsmen, Holborn, have offered the following Prizes for Vegetables grown by *bonâ fide* gentlemen's gardeners, or gentlemen amateurs, without forcing, in the open ground, to be awarded at the meetings of the Royal Horticultural Society during the present year—viz., *May 17th.*—Prize £1 10*s.*, for the best dish of Carter's First Crop Pea, 1 peck. Prize £1 10*s.*, for the best dish of Early Peas, not First Crop, 1 peck. *June 7th.*—1st prize £2 2*s.*; 2nd £1 1*s.*, for the best three dishes of Peas (to include Alpha and Invicta)—*i.e.*, Early White, Early Round Blue, and Early Wrinkled Peas. *June 27th.*—A silver cup or £10; 2nd prize £2, for the best collection of Vegetables, including Laxton's Supreme, Carter's Hundredfold, Laxton's Quality, Dwarf Waterloo, and two other varieties of Peas. *July 5th.*—1st prize £2 2*s.*; 2nd £1 1*s.*, for the best six dishes of Peas, to include Laxton's Supreme, Carter's Hundredfold, and Laxton's Quality. *July 19th.*—1st prize £2 2*s.*; 2nd £1 1*s.*, for the best collection of Vegetables, to include three dishes of Peas (including Carter's Imperial Wonder and Laxton's Supreme), Carter's Improved Garnishing Parsley, and Carter's Giant White Cos Lettuce. *August 16th.*—1st prize £2 2*s.*; 2nd £1 1*s.*, for the best collection of Vegetables, to include Carter's Champion Runner Beans and three dishes of Peas (including Carter's Imperial Wonder and Carter's Wonder of the World). *September 6th.*—1st prize £2 2*s.*; 2nd £1 1*s.*, for the best collection of Onions, to include the New Giant Rocca of Naples, Giant White Tripoli, and Neapolitan Marzagole. *September 20th.*—1st prize £2 2*s.*; 2nd £1 1*s.*, for the best collection of Vegetables, to include Carter's Dwarf Crimson Celery, Carter's Dwarf Mammoth Cauliflower, New Giant Rocca Onion, Kohl Rabi, three dishes of Peas (to include Carter's Imperial Wonder), and Carter's Perfection of Beets. *October 4th.*—1st prize £2 2*s.*; 2nd £1 1*s.*, for the best collection of American Potatoes, six varieties. *November 1st.*—1st prize £3 3*s.*; 2nd £2 2*s.*; 3rd £1 1*s.*, for the best collection of Potatoes, to include Carter's Ashtop Fluke, Cambridgeshire Kidney, Red-skinned Flourball, and Carter's Main Crop. Prize £1 1*s.*, for the best dish of Carter's Main Crop Potato. *December 6th.*—1st prize £2 2*s.*; 2nd £1 1*s.*, for the best collection of Vegetables, to include Carter's Little Pixie Savoy, Scotch Kale, Brussels Sprouts, Carter's Garnishing Kale, Parsnips, Scorzoners, Salsafy, and Leek.

THE LATE SEVERE WEATHER.

Mr. Adderley (page 66) calls attention to the injuries inflicted by the late severe weather, and, no doubt, facts will be revealed which are difficult to understand, for while he records the temperature with him at 1° below zero, on December 24th, none of the thermometers here (and there are three or four of them) descended below 13°, while less than a mile from us a temperature of 5° was registered, and at Tunbridge it had been down to 1°. At some places near Maidstone, 1° or more below zero was registered, and near Malling it is said 4° below that point. Now, a difference of 16° or 17° at places so near to each other is difficult to understand, altitude not always accounting

for it; and the effects produced show as well as the instruments that there has been a great difference, for while Mr. Adderley describes his shrubs as all but killed—a fact confirmed by others near here, where the temperature has been as low as with him—ours at Linton do not as yet exhibit any symptoms of having been injured. A few days ago, on examining the bloom-buds of Laurustinus, I thought they were not sufficiently injured to prevent them expanding at the proper time; but it may be too early yet to make sure of that, for at the time I write, January 27th, there is as much appearance of severe weather as a month ago.

It is singular that extreme cold should exhibit itself so capriciously—heat certainly never does, a difference of 2° or 3° is all that under ordinary circumstances occurs in the same exposure, &c., and is met with in places a few miles apart, while I believe differences of as much as 20° have been experienced during the past cold weather. Perhaps the almost entire absence of wind on the late cold nights had some influence, as a good breeze must mix one cold portion of the atmosphere with another that may not be so cold, and so produce a greater uniformity of temperature. The lowest reading of our thermometer at any time during the last twenty years was 6°, on March 10th, 1855, and 10°, on January 5th, 1867, while the memorable Christmas day of 1860 was only 15°, yet we suffered much that season, owing, however, to the unripened condition of vegetation when the frost set in, but not so much as in 1867. This season, with the prospect of more winter before us, it is too soon to say much, but so far, I believe, we have escaped with less damage than most of our neighbours, but when more certain of this I will probably revert to the subject. Meanwhile, it will be interesting to know where the most severe weather has been. A friend writing me from Cornwall says the thermometer there has been down to 14°, an unusual occurrence for that part of the country. In the midland counties, where we usually hear of the most severe frosts, it does not appear to have been so intense as nearer the east coast, neither does London appear to have been visited with such hard weather as many places in Kent. These and kindred matters are fitting subjects for inquiry, and when the time comes to reveal the damage done it is to be hoped the readings of the thermometer at each place reported upon will be given also. The fact of the ground being partly covered with snow was of much service to vegetables, the most damage to them being done after a partial thaw had set in about January 6th. The frosts that followed, though not so severe as before, certainly did more harm than those preceding that time.—J. Robson.

COMMISSION PAID BY TRADESMEN TO SERVANTS.

"A Tradesman" has written to us on this subject—a very important one—but we do not see what benefit would result from a discussion of the practice in our pages. Such discussions have already taken place, with little or no beneficial result, for though some gentlemen and tradesmen have manfully opposed it, others have tacitly or openly given it their approval, and too many employers look upon allowances on bills as making up for the deficient remuneration they give to their servants.

Not long ago a nurseryman told us that a gentleman in giving him an order said to him, that as it was near Christmas or bill-paying time, he must give a greater allowance to the gardener. "A Tradesman" justly states, the only right plan would be for employers to give remunerative wages, and oppose all such gratuities, and for tradesmen to join in resolving not to give them—but will they do so? It is quite a mistake to suppose that the gentleman gains in the long run, for if the tradesman pays so much in discount, he must contrive to get that extra somehow. All such allowances are very pressing in these days of close-cutting contracts. The whole system has a tendency to put a temptation in the way of all concerned to veer somewhat from the straight line of rectitude, and it is most desirable that we mortals should not have inducements to wrong-doing put in our way.

As to a gardener making a demand as a right of 5 per cent. on the cost of houses erected, we hope he will think twice before he persists in the demand. A gardener of some years' standing tells us he has had enough of self-respect to keep him from condescending to ask for a penny from his employer's tradesmen. There are, however, generally two sides to a tale. We have known cases where the intellect, the experience, and the extra time of servants had been fully employed by a tradesman, and without these that tradesmen could not have done the work at all, and yet not a hearty "thank you" was returned as an equivalent. In such cases, we think it is honest and fair that for such extra labour there should have been a tangible equivalent.

The gardener we have referred to says, "I can bring to my mind's eye a case of a great deal of work, building, &c., being done in a garden, and the gardener, feeling interested in the whole matter, did very much for the tradesman—what he would otherwise have been obliged to employ a clerk of the works to superintend, and did all this at his request. The gardener fairly thinking that he deserved something for his great extra labour, spoke, and we think rightly, to his employer; but was at once told it was no business of his, it was entirely a matter for the tradesman. Like many more of the most respectable servants, who would be glad to see the whole system of discounts and gratuities swept away, he was too proud to say a word to the wealthy tradesman who had freely used his time and abilities, and the only thing he ever received was half a sovereign to give some beer to the garden men. No doubt such are exceptional cases. I dislike the whole system of gratuities, but at the same time I think that extra work with head or hands should be fairly paid for."

On the whole, until gentlemen unite to set their faces against the system, until they cease to demand their 5 per cent. discount when they pay their own bills, until they give suitable wages, independent of all such degrading gratuities, and until tradesmen cease to encourage the system, and even outbid each other to obtain a job, we can only regret so great an evil.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Attend to the drainage of the garden, for at this season, when it is frequently requisite to fork and turn over ground previously trenched, it is easy to perceive the great importance of efficient drainage. I allude, of course, to soils which require draining, because some do not. How the earth crumbles down and mellows, and how much sooner it is in a fit state for cropping, when the drainage has been properly attended to. If the soil is undrained, the labour is far greater to get it in anything like condition for the reception of crops, and even then the advance and produce of the crops committed to it are greatly inferior. A thoroughly efficient system of drainage is the basis of all successful cultivation. Continue to manure, trench, and fork over the ridges whenever the weather will permit. Fill up any vacancies in the autumn plantation of *Cabbages;* also make fresh plantations of the autumn sowings, if necessary. *Cauliflowers* under hand-glasses and in frames must be fully exposed in mild weather, or they will button off in the spring. Sow seed on a south border to produce plants to succeed the autumn sowing. Sow *Celery* seed in boxes, and place them in a forcing house to produce plants for an early crop. Where the soil is not wet and stiff, *Garlic* and *Shallots* should now be planted, if not done in the autumn; plant in rows at 6 inches apart. *Lettuces* in frames should have all the air possible in mild weather; make a sowing on a south border to succeed the autumn sowing. *Potatoes*, where there are no frames or pits, plant on a south border for an early crop. Pots may now be placed over the roots of *Rhubarb*, and covered with dung or leaves. A small sowing of *Spinach* may be made between the rows of early Peas. Where young *Turnips* are required early, a sowing should be made on a slight hotbed.

FRUIT GARDEN.

Examine Fig trees covered up, and see if the mice have gnawed off the bark from the stems. Traps should be set in different parts of the garden to catch them. They will now more readily take the baits than they will when there is other food for them. Pruning and nailing Peaches, Nectarines, and Apricots, may be followed up with vigour and perseverance whenever the weather is favourable. Wall fruit trees of any kind that are becoming crowded with wood near the top of the wall should have some of the large branches headed back, and the shoots trained below. Do not crowd the centre of fan-trained trees with too much wood, that part will always fill up enough.

FLOWER GARDEN.

There are few things in gardens we are more dissatisfied with than the usual mode of planting shrubberies; there is generally no attempt at arrangement, and where this is neglected at the time of planting, no after-thinning or removing, short of taking up the whole of the plants, will give them the effect they should produce. In planting shrubberies, those plants which are intended to remain permanently should be first planted, and at such a distance apart and from the walks, as not in any way to interfere with one or the other for, say, ten years. This will allow many of the plants to attain a large size, and to show their proper character. The intervening spaces may be filled up with whatever plants may be at hand, and as they encroach upon the permanent plants they should be removed. Shrubs will not then require pruning, which, with digging about their roots, is the worst practice that can be followed for the production of handsome plants. Take every opportunity to forward the ground operations in this department. Now is an excellent time for the formation of beds of Bourbon, China, and Tea-scented Roses. These classes of Roses will flower throughout the summer and autumn months; they give little trouble after planting, and they deserve to be cultivated in preference to many annuals which we frequently find in flower gardens. To have them in perfection it is necessary to take the soil out of the beds to the depth of 12 inches, fill up with rotten dung from an old hotbed or any

other source, tread it firmly as the bed is filled up, place 3 inches of soil on the dung, and plant in the usual manner. Prepare beds for Carnations and Pinks; strong turfy loam, with rotten cow dung or sheep's dung, forms an excellent compost. Have the Pansy beds in readiness; choose a strong rich soil in a shady situation if the blooms are wanted in a state of perfection. Top-dress Auriculas and Polyanthuses with light loam made rich by the addition of rotten cow dung. This is a good time to take off the offsets before top-dressing; plant from three to four in a 5-inch pot, and place them in the shady part of a frame. Sow seed in shallow pans, and place them in a cold frame. Place Dahlia tubers in a little heat to start shoots for cuttings.

GREENHOUSE AND CONSERVATORY.

Attend to former directions as to the temperature and ventilation of the conservatory, guarding against extremes during the present piercing weather, and taking care, by moistening the heating apparatus twice or thrice a-day, and some of the vacant places about the house, to make up for the loss of moisture which will now be deposited on the glass. Flowers will not keep in dry air, therefore you must pay some attention to the hygrometric state of the atmosphere. Remove the plants to the house as fast as they come into bloom, altering the arrangement frequently so as to impart a fresh appearance to the display. Return all plants to the stove or greenhouse as they go out of bloom, and such plants as Euphorbia jacquiniæflora, Poinsettias, and others, which have done blooming, may be set aside and kept comparatively dry for a time. It may, perhaps, be necessary to top-dress or renew the soil around some of the borders; if such be the case, let it be performed before the end of the month, and give the plants a good soaking of clear weak manure water at the same time. In the greenhouse, while the present severe weather continues, but little can be done with the specimen plants, except that they may be trained and washed; indeed, in smoky or dusty places the washing of large plants by laying them on their sides and giving them a regular deluging from a good syringe is a matter of considerable importance, and tends much to their healthy and vigorous growth. Proceed with the potting of young plants and small specimens of all kinds, using the soil tolerably rough, with plenty of sand and drainage, and keep them comparatively close until they make fresh roots. This is a good time to start a collection of Kalosanthes, potting them in a compost consisting of two parts sandy turfy loam, one part turfy peat, and one part of half-decomposed leaf mould, with plenty of coarse gritty sand, and a liberal admixture of potsherds broken small. Give them a liberal shift, and keep them in a temperature of from 40° to 50°, and as soon as they make fresh roots stop each shoot, and train the plants into form. If the weather is favourable endeavour to get all the plants which require it shifted by the end of the month, taking care to moisten the old ball properly before they are shifted, and also to guard against over-watering afterwards. Attend to the training of Tropæolums and other climbing plants, and shift the former into their blooming-pots, if not done already. Plants of Polygala or Boronia which are getting too forward must be placed at the cool end of the house, and others which are late must be generally excited—that is, if they are required to bloom early.

COLD PITS AND FRAMES.

Plants in these must be thoroughly protected, and if any of them get frozen let them be thoroughly thawed before exposing them again to light. Give abundance of air at all favourable times, and endeavour to keep the air as dry as possible. Look to Liliums now breaking through the ground, and take care that they are not injured by stagnant moisture about the young shoots.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

WE have had another week of frost and snow, in which but little could be done out of doors but wheeling and turning soil, and digging when the snow had left us for a time. In the way of protection, young Cauliflowers under hand-lights have only seen the light for a short time when there was the appearance of a little sun. On the whole such vegetables have stood well. Many other things have been treated the same way, and trouble has been saved in uncovering, and the plants do better than when exposed to sudden changes as respects cold and excitement to growth. Many vegetables, as old quarters of Cabbages, have suffered much, and would have suffered more but for the slight falls of snow that gave them some protection. It will be wise policy to sow Cabbages, Lettuces, &c., in a little heat, to provide for what may yet take place, as a rising barometer and a keen north wind would seem to imply that the frosty weather is not yet over.

We have lots of Potatoes grown a few inches in pots, and we would have been glad to have turned them out into beds, &c., but we had not a single day in which it was warm enough to do so with safety. It is remarkable how soon a *sudden chill* will affect plants for a long period. This is a simple matter that many people cannot be brought to see. In fresh potting, planting, &c., plants that have received anything like nursing treatment should be removed from it as short a time as possible, and if changes must be given as respects temperature they must be gradual. As a general rule, when plants are removed to a shed to be potted, the shed some degrees above freezing, say from 40° to 45°, they should be taken back again as soon as possible. How often does it happen that scores are thus treated before being taken back again to the houses, when it would be more workmanlike in every way to take only a few out, replace them, and then bring back more. It may seem stretching the point too far, but we honestly believe that allowing plants to stand exposed for two, three, or four hours in a place 20° or 30° colder than that whence they came, instead of for the shortest possible time, gave the plants a severe check, and necessitated many a puff of tobacco that otherwise might have been saved. Not long ago a gentleman told us he could have bought all the flowers he had grown for the amount the frequent smokings cost him. We have frequently known plants standing in a temperature of from 55° to 60° taken into a shed at 40° the first thing after breakfast, and after repotting left standing there until far in the afternoon. Why, the very potting would give a check if the soil was at all colder than the temperature of the house—that would be check the second; and the diminished temperature of the shed for so long a time would be check the third; and if coolish water instead of water at from 60° to 70° was used, that would be a fourth check; and yet people are amazed when the once-fine leaves get covered with insects, and washings and smokings must be resorted to to keep the plants alive. Plants are just as sensitive to extremes of temperature as we are, and even much more so. We would not like to expose the growing shoots of even a Potato in a frosty day, and in such matters a little delay is often, after all, time and future well-being secured.

A supply of Rhubarb, Asparagus, and Sea-kale is a great help now, when, for the present at least, we cannot say much as to the gathering of Broccoli out of doors. As lately stated, all the three may be grown anywhere in the dark, provided a little mild heat can be obtained. The Asparagus must be greened by exposure to light afterwards; but Rhubarb, if not allowed to grow more than 8 or 10 inches for the large kinds, and shorter for the smaller kinds, does well without any light, and cooks not only very tender, but crisp and firm enough for anything. When drawn up long it becomes watery, and at times a little stringy. Those who have Swedish Turnips may get blanched or green tops by placing the tubers in a little heat. These make a delicious vegetable in winter.

FRUIT GARDEN.

Planting, if to be done, is quite out of the question. Even though trees could be taken up and laid out, and thus covered, there has not been a day of late but the exposed roots would have been frozen, and that is a thing that never takes place in nature as respects the bulk of our fruit trees. If the frost does reach the roots it reaches them very gradually, and there is darkness and the covering over them, instead of the direct exposure.

Pruning Fruit Trees.—We did a little on the most favourable days, and must hurry on as soon as the weather is at all fitting, as other out-door work for which the weather was very suitable prevented our doing more in this direction. Pruning is work that can be done at any time, when at all fair overhead, and felling trees, and grubbing up, are excellent work for cold, frosty weather in winter. Would there were more of such work to be done in this district. It is sad, indeed, to see so many men anxious to get employment, and unable to find it, in this severe weather. We fear that many of our labourers have suffered as much from scarcity of food, of fuel, and of clothing, as the beleaguered Parisians. What can we expect, when the weekly wages can do little more than secure very moderate comforts, if these wages altogether, or nearly so, cease for six or eight weeks at a stretch? It is all very well to speak of improvidence when all is prosperous, and to show that by care-

fulness and prudence there would have been loaves in the cupboard instead of empty shelves; but unfortunately referring to the past will not bring the bread, to say nothing of the beef, for the present. The greatest kindness to such people would be to give employment, and, in some cases, a little advance to the most distressed. In many places a good deal could be done at such jobs as those referred to above, with great benefit to the employed, and often to the advantage, or, at least, the no great loss of the employer. What is thus spent in labour will in its results be a very different affair from that given in mere charity, either personally or through clubs and societies.

Strawberries in Pots.—On some of the coldest nights, besides old sashes, we threw a little litter over the pots. The frost, however, has never injured us to the extent that mice and rats have done. We have already lost some scores of pots from the buds of the plants being eaten out, and that independently of rings of tar round the beds, trapping, and even shutting cats up where the plants were. Our losses this year, however, are small in comparison of what we have suffered in some seasons. Forward pots will be all the better of having the blooms dusted, using fine feathers, a camel's-hair pencil, or even a dry hand gently. As lately alluded to, plants coming on gradually, and not yet showing, should be rather under-watered, and no water should stand in the saucers. Hence beginners will be safer if the pots merely stand on boards.

Peach House.—Owing to alterations and fresh work in other houses, our Peach house is so crammed with plants above and below, as scarcely to give 1 foot of path or moving room. Hanging and other shelves have been so relieved as to permit of Strawberry pots being placed on them, and the fruit trees, from the heat used to keep all the plants safe, are coming into bloom near the heating medium. For the last fortnight we have scarcely had an hour's sun all put together, and, therefore, to fertilise the forward blooms, a thin piece of wood, to act in the way of a fan, has been waved over and close to them, so as to help to disperse the pollen, and some very soft feathers, as from the breast of a partridge, have been used for the purpose, as specified above for Strawberries. These modes are chiefly required in such very dull weather, and they will be most effectual in securing their object when the sun peeps out, if only for a few minutes. Nothing can quite make up for the want of the sunbeam in such cases, but something may be gained by the modes referred to, and still more by a low temperature in proportion to the weather securing strong blooms, instead of weak ones in a somewhat high temperature uncounteracted by the strengthening rays of direct light. In such weather we would rather have a Peach house below 50° than above it at night, with a rise of from 5° to 10° during the day; but if the day was sunny, and air given early, however little, and the rise in temperature gradual, we would not object to a rise, from sun heat alone, to from 5° to 25° higher. We would far prefer that gradual rise to admitting great blasts of cold, frosty air. In such cold, unsettled weather, when fire heat must generally be resorted to in the morning, the chief danger will come from a strong fire heat and a bright sun heat being allowed to act together, and this can only be prevented by the care and attention of the person who, in firing and air-giving, attends to the houses. When sun is expected it is always well to let the fire heat become gradually reduced as the sun gains power, and the fire heat again begin to tell as the sun heat declines.

ORNAMENTAL DEPARTMENT.

Here the chief work of routine, as alluded to in previous numbers, has been cleaning, attending to plants in houses, bringing forward Roses, Deutzias, &c., and bulbs in heat, taking off and inserting cuttings of plants, of which great quantities will be wanted in summer, and preparing for sowing such annuals as Lobelias and Petunias. Preparing for slight hotbeds has also occupied some time.

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

Books (*Auricula*).—You can have the three books you name free by post from our office if you name them, enclose eighteen postage stamps, and send your address. (*M. G.*).—Keane's "In-door and Out-door Gardening" contains complete monthly directions for in and out-door gardening. You may have the two volumes per post from our office for 3*s.* 4*d.* in stamps.

Tax on Gardener—Gun License (*Constant Reader*).—You must make a return of your gardener on the schedule of taxes. Unless you take out a game certificate, you must have a gun license to entitle your gardener to shoot small birds.

Foreign Nurserymen's Prices (*G. S.*).—We are quite aware that they are much lower than those charged by nurserymen in England, but unless plants are purchased in large quantities the expense of carriage renders those prices quite as high. Competition is so active here that if a living profit could be made out of lower prices, some nurserymen would soon adopt them.

Italian Seeds (*J. E. B.*).—We cannot name plants from seeds.

Red Lead on Seeds (*W. C. W.*).—It has no injurious influence in any way. The subject was remarked upon in our eighteenth volume.

Acorns in a Bottle of Water (*J. B.*).—They are only so treated as a curiosity, so you may keep them there as long as you please.

Peaus Decaying at their Cores (*Europa*).—Some varieties are more prone than others to blet like their near relative the Medlar, and those you sent are two of them. No reason has been assigned for this. If ripening was hastened by keeping the fruit warm and in the light, the exterior might ripen before the interior began to blet.

Palm Seeds Sowing (*Delta*).—The kinds you name, like all the tribe, are easily raised from seeds, but these are slow in vegetating. They may be sown now singly in small pots in a sandy-peat compost, and the pots should be plunged in a hotbed at 85° or 90°, and if there is a top heat of 70° to 75°, with a rise from sun heat to 85° or 90°, they could not be better. The soil must be kept moist, and a close moist atmosphere is desirable. They may vegetate in from six weeks to three months, but, if they do not, have patience.

Abutilon and Lantana Treatment (*Idem*).—The former is a greenhouse plant, so is the latter, but both may be used for flower-garden decoration from May to October. We presume they are now kept rather dry. In February, or early in March, prune them if at all straggling, cutting them pretty closely; indeed, we cut ours closely in, like a Rose bush, to two or three eyes, shake the plants out of the pots, reducing the ball considerably, and repot in a compost of light turfy loam, with one-third leaf soil, and a free admixture of silver sand. Liberal drainage is given, and the plants are sparingly watered for a time, but sprinkled overhead two or three times a-day with aired water, and when they are growing freely liberal supplies of water are given. The plants should be shifted into their blooming pots by the beginning of June. A light, airy position in a greenhouse suits them.

Melon for Frame (*C.*).—Your deep wood frame will be suitable for the hardier sorts of Melons. If you can command enough stable dung to fill the frame to within a foot of the glass, you will be enabled, from the bottom heat to grow Beechwood or Heckfield Hybrid, both good, free-setting kinds. We would fill the frame with the hot dung by the middle of April, and when it had settled down, or in a week, we would level it, and put in the centre of the bed a ridge of soil from 10 inches to a foot in depth, and with a base twice as great, covering the dung all over about 3 inches deep. When the compost is warmed through we would turn out the plants, one at every 2 feet, the end plants being 1 foot from the ends. This is better than planting two plants under each light. When the plants commence to spread their vines, add more soil, so as to cover the bed 10 inches deep. The best compost for Melons is a strong loam, and if turfy all the better. It should be chopped and made firm. No manure is necessary; but if you cannot obtain hot dung, then you may add to the compost one-fourth of well-rotted manure, mixing it well. Failing the hot dung, you will need to grow what are known as the hardy ridge varieties, and of those Achapesnorricher is the best. The plants should be raised on a hotbed, though the variety named will do sown where it is to remain.

Roses for Early Blooming (*H. Foy*).—Your plan of growing Roses in pots plunged in summer and winter, for early blooming in an orchard house, is quite feasible. We should advise their being grown either on the Manetti stock or on their own roots, and amend your list as under:—*Pole Roses:* Gloire de Dijon, Général Jacqueminot, Madame Charles Crapelet, Paul Verdier, Madame Clémence Joigneaux, John Hopper. *For Pots.—Hybrid Perpetuals:* Charles Lefebvre, Pierre Notting, Madame Caillat, Alfred Colomb, Boule de Neige, La Ville de St. Denis, La France, Senateur Vaisse, John Hopper, Duke of Edinburgh, Madame la Baronne de Rothschild. *Bourbon:* Souvenir de la Malmaison, Louise Margottin, Michel Bonnet. *Noisettes* same as list, Céline Forestier, Cloth of Gold, Maréchal Niel. In addition to these you ought to grow some *Tea Roses*—viz., Madame Bravy, Madame Willermoz, Madame de Vatry, Marie Ducher, Adam, Souvenir d'un Ami, La Boule d'Or, Alba Rosea. The best soil is the top spit of good pasture loam mixed with one-third good decayed manure, and a few bruised bones and pieces of charcoal; use sifted cinders as drainage.

Good Roses of Recent Introduction (*C. A. Smyth*).—Alfred Colomb Abel Grand, Berthe Baroo, Boule de Neige, Duke of Edinburgh, Elie Morel, Fisher Holmes, Horace Vernet, La France, Madame la Baronne de Rothschild, Julie Touvais, Mdlle. Marie Rady, Marguerite de St. Amand, Marie Baumann, Princess Mary of Cambridge, Monsieur Noman, Monsieur Woolfield, Xavier Olibo, Marquise de Mortemart, Madame Creyton, Thyra Hammerick, Adolphe Brongniart.

List of Roses (*R.*).—Instead of Madame Canrobert, Comtesse de Paris, Meyerbeer, J. Keynes, Alba Carnea, Exposition de Brie, and Alpaido de Rotalier, we should name Charles Lefebvre, Alfred Colomb, La Duchesse de Morny, Madame la Baronne de Rothschild, Monsieur Noman, Madame Caillat, and La France. The others in the list are very good.

Showy Climber for Greenhouse (*Idem*).—For winter blooming there is no better climber than Kennedya Marryattæ, a scarlet Pea-shaped flower, with handsome trefoil foliage. For spring and summer you might have Clematis Jackmanni, deep violet purple, or Clematis Sieboldi, lilac white with violet stripes. Nearly all the new Clematises are valuable as greenhouse climbers, and, being hardy, are not injured in severe winters. Tacsonia Van-Volxemi, with pendant (Passion-flower-shaped) scarlet flowers, is also a very free, showy climber, but requires plenty of space. Some of the Tropæolums of the elegans race are well worth growing as greenhouse climbers. The hardy Passiflora cærulea forms a valuable climber for covering a back wall, as the foliage is very ornamental, and it will succeed with a north or east aspect. If your greenhouse has an intermediate temperature we can recommend the old Plumbago capensis, with its soft French-grey flowers, as a very valuable plant trained as a climber, either for a pillar or back wall.

Cactus Culture (*Idem*).—Large Cactuses ought to be kept on shelves

near the glass, and dry at the roots, during the winter months. They do not require much pot room, and ought not to be repotted till after they have done flowering. Give water when they begin to show their buds, and do not let them want for water during the blooming and growing season. An intermediate temperature suits them best. Some of the Cactus tribe —the Cereuses, Epiphyllums, and others make good plants for hanging baskets.

Phalænopsis Bearing Young Plants (*A Reader*).—All the species of Phalænopsis do more or less freely produce young plants on their flower spikes after they have finished blooming, P. Lüddemanniana being the most prolific, and P. Schilleriana the shyest in doing so. Probably the reason the latter kind so very seldom produces young plants in this way is that the flower spikes nearly always die back soon after the flowers fade, and thus there is no time for the development of any latent buds, whilst the spikes of the other species live for several years. We have only once seen P. Schilleriana produce a young plant in this way.

Geranium Leaves Blighted (*H. A. K.*).—Your question was answered two weeks since.

Manuring a Lawn (*J. W. M.*).—Nothing would do your lawn so much good as dressing it early in March, or as soon as the ground becomes thoroughly thawed, with short manure. Spread it regularly, and let it lie until April; then, after a shower, rake the lawn with an iron rake—you need not fear damaging the grass—and this done sow over the lawn Suckling Clover (Trifolium minus) at the rate of 12 lbs per acre, and your soil being light and gravelly we would add 1½ lb. Bird's-foot Trefoil (Lotus corniculatus minor). Rake over lightly after sowing, and roll well with a heavy roller, but you must have the lawn in such a state that the soil does not adhere to the roller. An ordinary garden roller will answer. We think you will have a good lawn by the time hot weather sets in.

Melon for Exhibition early in June (*Idem*). — To have Melons ripe early in June we sow in the first week in February, and grow the plants in a pit or house heated by hot water. In a dung hotbed, ripening them at the beginning of June is very uncertain. Williams's Paradise Gem is a good early scarlet-fleshed kind, and Meredith's Hybrid Cashmere, a fine green-fleshed variety. Plants of Show Pelargoniums for exhibition early in June we should select now out of what nurserymen term half specimens, which are usually two years old.

Cyclamen persicum Varieties Raising (*W. R. N.*).—We do not see why you should not add the Cyclamen to your greenhouse plants. It will thrive admirably in such a structure as you describe, and we have no doubt that by following the instructions given in this Journal by Mr. Edgerton, page 24 of the number for January 12th, you will flower them within twelve months. You best place for raising the seedlings will be the Cucumber frame, which you start early in March, and by continuing them in bottom heat you may have them in flower this time twelvemonth. A packet of seed will cost from 1*s.* 6*d.* to 2*s.* 6*d.*, according to size. The largest will be sufficient to give you several dozen plants; we have had five dozen from a 2*s.* 6*d.* packet of seed. Any of the principal seedsmen could supply you with seed; we never depart from our rule not to recommend dealers.

Roses in Pots (*Idem*).—The soil in which you have potted your Roses is just what we use for Tea-scented, China, and Noisette Roses in pots—*i.e.*, the top inch or inch and half of a common where the soil is a light vegetable soil, half peat half loam, or something intermediate between the two, adding about one-third of rotten dung. Our Roses succeed well in it, and we have no doubt yours will, as the compost answers well for Geraniums. The soil you have used could not have been better. Roses in pots, and especially those on their own roots, do best in a light soil. Stiff clay soils no doubt suit the Briar, but are totally unsuitable for the kinds you name. We would not repot them again now, but give them a trial.

Lapageria rosea in a Pot (*T. W.*).—Pot it now, if not already done, and in what would be considered a large pot for other plants. Provide efficient drainage, and use a compost of fibrous brown peat torn in pieces but not sifted, adding silver sand liberally. Pot so that the setting-on of the roots may be just covered with soil. Give an abundant supply of water, and afford it a light, airy position in the greenhouse; all the better if shielded from the bright midday sun without resorting to artificial shade. Train the shoots to a flat or table-like trellis. When it is growing it will require water every day. The soil must always be kept moist. When growing freely it cannot have too much water.

Celery Culture (*A. B.*).—To cultivate Celery successfully you must sow the seed early in March in pans of rich light soil, just covering it with fine soil. Place the pans in a gentle hotbed or house with a temperature of from 50° to 60°. When the plants appear keep them near the glass, so as to prevent drawing, and when they have made the second rough leaf prick off about 2 or 3 inches apart on a slight hotbed, covering the bed with about 3 or 4 inches of fine rich soil. Protect with a frame and light if practicable; if not, use mats supported by hoops stretched across the bed. The mats may be removed in mild weather, but should remain over the plants for some time after pricking out, so as to screen them from powerful sun, and at night, if frosty, the mats should be placed over the plants. If in a frame the plants will need shade from bright sun until established. Admit air abundantly whenever the weather is mild. Harden well off before planting out, and attend to watering. At the end of May or early in June they should be planted out. Make trenches 15 or 18 inches wide, 4 feet apart, and 15 inches deep, and place in each not less than 3 inches, and better 6 inches, of well-rotted manure. Dig in the manure at the bottom of the trenches, and then fork well over prior to planting, breaking the clods and mixing the manure thoroughly. Plant about 9 inches apart, removing the plants with a good ball, and water well at planting, and afterwards two or three times a-week if the weather be dry. When the plants are growing freely copious waterings of liquid manure may be given twice a-week with advantage. In earthing-up, carefully close the stalks, so as to keep out the soil. If you wish for an early crop, sow in February and grow the plants in heat; they will be fit to plant in the trenches in May. For a late crop sow at the beginning of April, pricking out in the open air as described for those sown in March, and plant out in July. We grow Sandringham White and Ivery's Nonsuch, and about four other sorts, but the two named we like best. The "Garden Manual" contains full instructions for Celery culture. It may be had post free from our office for twenty stamps.

Cyclamen Atkinsi Seed Sowing (*W. S.*).—Sow the seed now, or not later than March, place it in a gentle hotbed, pot off the seedlings singly when large enough to handle, return them to the hotbed, continue to grow them in gentle heat, and in autumn remove them to the greenhouse. The treatment does not differ essentially from that of C. persicum, and as you have been successful in flowering it in ten months from the seed, we have no doubt you will also succeed with C. Atkinsi. The seed you have had could not have been good. Try again. We usually sow ours in autumn as soon as ripe, and place the pan on a shelf in the greenhouse, for though the forcing of these plants is all the rage just now, we do not think it necessary for successful treatment. It remains to be seen what will be the result of the forcing treatment on the plants in a few years. Ours have no bottom heat in any of their stages, at least not after the first year, for we do not think plants nearly hardy (some of them quite so) in any way improved by a temperature greater than they naturally require.

Orchids for Cool Conservatory (*Beechwood*).—We have no doubt the following Orchids would thrive well in the temperature you name, 40° to 50°; but then the house must not be treated as an ordinary greenhouse. Such plants as Fuchsias, Geraniums, and others like to have the side lights open, so that the air may blow through them, but this does not suit Orchidaceous plants, for although they have plenty of wind and full exposure to air in their native habitats, yet it must be remembered that wind with us, and also our entire atmosphere, usually tend to dry up moisture, but in the Orchid regions the atmosphere is heavily charged with moisture. In a temperature of from 40° to 50°, the following Orchids may be grown if the air be kept charged with moisture, and not so much air admitted as is usual for ordinary greenhouse plants:—Ada aurantiaca, Anguloa Clowesii, Arpophyllum giganteum, Cattleya citrina, C. maxima, C. Trianæi; Cymbidium pendulum, Cypripedium insigne, C. caricinum, C. Schlimii, C. vennstum; Cœlogyne cristata; C. corrugata; Dendrobium Hillii, D. nobile, D. moniliforme, D. speciosum, D. linguæforme; Epidendrum ibaguense, E. vitellinum; Barkeria Skinneri, B. spectabilis; Lælia albida, L. autumnalis, L. majalis; Lycaste Skinneri, Mesospinidium sanguineum, Odontoglossum Alexandræ; O. Bluntii, O. luteo-purpureum, O. grande; Oncidium nurosum, O. bifolium, O. nubigenum, O. Phalænopsis; Phajus grandifolius; Pleione maculata, P. lagenaria, P. Wallichii; Sophronitis grandiflora, and Zygopetalum Mackayi.

Pine Apples with Large Crowns (*Pine*).—It is chiefly attributable to weak growth, and in your case probably arising from the plants being too far from the glass; they cannot be too close to it if the leaves do not touch it. The plants are grown too close together; give them more room, all the light possible, and plenty of air. With good, stiff, sturdy plants you will obtain a greater weight of fruit from a given space than you will from one-third more plants in the same space. Another cause of large crowns is the plants being old, for these generally have a large leaf development, and afford comparatively small fruit.

Vinery Planting (*Ten-years Subscriber*).—We regret you have arranged to plant the Vines outside. Could you not alter this and plant them inside? It might easily have been effected by having the front wall pillared, which we think it must already be, as the border is inside as well as outside. Plant inside by all means, if you can, and if you cannot, we do not see the utility of your inside border. The bottom being a sandy rubble there is no necessity to concrete. We apprehend you do not wish for sorts that require a high temperature, but such as succeed well with Hamburghs, which you mention. In addition to the three Hamburghs you will have room for ten Vines. We should plant them 8 feet apart, the end Vines 18 inches from the ends. We should plant two Black Hamburgh, two Frankenthal, two Trentham Black, one Black Prince, one Buckland Sweetwater, two Foster's White Seedling, one Trovêren Frontignan, one Golden Champion, and one Generaldelia Marmora. We have omitted the Muscats and late Grapes, which require more heat than the preceding, and are best grown by themselves; indeed, they cannot well be grown in a miscellaneous collection. We would not plant any fruiting Vines, but would have those known as strong planting canes, nor would we introduce any Peaches or Apricots in pots, as they will not do well more than three years. No doubt they would do well this and the following year, if you obtain trees in a bearing state. They will, of course, require to be in pots.

Paying with Fuel, &c. (*H. A. D.*).—In this matter we have no experience. We consider it to be a bad plan to pay in milk, Potatoes, peat fuel, &c. Six inches of thatch would do for the sod-covered ice house.

Orchard House Fruit Trees (*C. T.*).—With Peaches on the back wall, we think that one cane would have been enough for each Vine. We should be disposed to leave two in those cases where they were extra strong and the contiguous Vines weak, until they gathered strength. Even the strongest of the Vines we should never think of leaving the length of the rafter. By doing so, if the wood is well ripened, you may have a lot of fruit this year, but your Vines will do little good afterwards. A few of the strongest we would leave half their length, the others one-third, and the weakest less. A little sacrifice now with young Vines will be gain in the end. A shady pit will not do for early Vines where the heat is deficient. If the damp is too much, you must cover the hot-water tank more securely. Under the circumstances the beginning of February would be early enough.

Cucumber House (*T. M.*)—In reference to the Cucumber house alluded to at page 55, the further information is given that the house is span-roofed, that there is to be a bed on each side, that the house is to be heated by a flue, and the chief questions are, How is top and bottom heat to be obtained, and whether earthenware tiles or bricks would be best for use? First, then, earthenware tiles would be of no use for such a purpose. You will require a good strong flue of bricks all round. For such a narrow house, 8 feet wide, we would have been satisfied with a bed in front, and the flue going through that would have given bottom heat to the bed, whilst the back flue would be for top heat. For such a purpose we would make the first 6 feet of the flue from the furnace brick-on-bed, and the rest all round brick-on-edge. A flue 9 inches wide inside and 14 inches deep would be required, to be covered with strong tiles, with the tiles beneath to cross the joints. Then there are various modes you might adopt. First, Take a 4½-inch brick wall all round inside, or at least on both sides, as the boundary of the beds inside, make an open bottom of slates, &c., 4 inches above the flue, and have openings in the wall to put water into evaporating-pans on the flue. These openings with slides will enable you to let the air, heated or moist, into the atmosphere of the house. Another plan is simpler still. Make the inside next the pathway-side of your flue 4½-inch work, or brick-on-bed all round, when you cover the flue raise these walls at the side to the necessary height, between the flue and the outside walls fill in as

hollow as possible with clinkers and brickbats, put one layer over the flue likewise, and finish all across with fine-washed pebbly gravel, so as to make the bottom for your earth bed. Before finishing the open rubble, fix upright at every 3 or 4 feet a drain-tile of 3 inches in diameter, to be supplied with a plug above the soil's level; when you pour water down among the rubble it will rise again in vapour as you work, and you will remark, by so doing, the water will never come directly on the flue. By this means you can have top heat moist or dry. The inside of the flue will be for top heat, and the top and the sides next the outside walls for bottom heat. There can be no plan simpler and more economical under the circumstances.

Flower Garden Plan (*M. X., Cheshire*).—We think your proposed border would look better if the Cerastium were continued on both sides, though of unequal widths, interrupted now by the angles of the diamonds. This would reduce the latter, but that would be an improvement, as making all more uniform in size. Making the connecting lines of 2 (Lobelia) wider, would on the same principle be an improvement. The Aurea floribunda Calceolaria, if young dwarf plants, will do very well. Of the Nasturtium and Petunia in diamonds we are more doubtful, as the one will need so much picking, and the other so much pegging. By lessening the diamonds and the Cerastium, and widening the Lobelia, then having the diamonds of yellow and dwarf scarlet Geraniums would look well.

Hares Barking Fruit Trees (*Lady Waterford*).—Though the bark of your fruit trees has been damaged by hares, in all probability the vital portion or inner bark has not been so destroyed, but if properly protected at once, it will be able to perform its functions in the next season. For this purpose let all the wounds be covered as soon as possible with the mastic L'Homme Lefort, or any sort of grafting-wax. The plaster made of cow dung and clay applied to the wound and bound round with old sacking, will answer very well in the absence of the mastic. The best preventive we know against these ravages of hares and rabbits, is to dip strips of brown paper in gas tar, and when dry to bind them round the trees.

Parentage of Auriculas (*G. S.*).—"I believe it to be generally acknowledged, that the parent of both the Alpine and florists' Auriculas is the Primula Auricula. As to the two kinds not crossing, so far is that from being the case, that many Auricula growers will not allow any Alpine near their florists' varieties for fear of deteriorating the seed, the Alpine being more vigorous and exercising a very marked influence on the seed vessels.—D., *Deal*."

Begonia fuchsioides with Small Flowers (*A Lady in Cheshire*).—The smallness of the flowers is owing to the growth being weak. The only way to remedy the defect is to grow the plants in a more airy lighter structure, so as to secure strong, short-jointed, firm shoots, and then we have no doubt the flowers will be larger, for as the wood is so are the flowers. They would do better in a vinery in summer than in a close stove, which is apt to cause weak shoots. Cut away the weak old growths and encourage fresh shoots from the base. Ours are now sending up several strong young shoots, and in about a month they will be in a vinery at a temperature of 50° to 55° at night. When the plants are flowering, or rather when they begin to show flower, they are benefited by the application of weak liquid manure two or three times a-week.

Oleander Bare at Bottom (*Idem*).—There is no remedy but to cut it down to within 6 inches of the pot, and we should do this early in March, keeping the plant rather dry, and then to encourage it to break freely we would place it in a vinery or other house with a moist gentle heat. You may make cuttings of the upper parts. The points of the shoots, cut off from 4 to 6 inches long, strike freely in sandy soil on a hotbed. The old plant will not flower this year, but should have every encouragement, being potted when it has made shoots a few inches long. If you have room we would not cut the plant down, but keep it as a standard; nothing can be finer than a standard with a good head on a 6-feet stem. Ours are bushy plants about 6 feet high, with from six to a dozen shoots starting from near the soil. If you keep the standard, strike cuttings early in summer, and grow the plants as dwarfs, by stopping them when 6 inches high to induce side shoots, which should be again stopped; you will thus have plants feathered from the pot, but they will not be in a blooming state for three years.

Shrubby Calceolarias Raising (*J. D.*).—Between the present time and March you may sow the seed in pans well drained, and filled with a compost of light turfy loam two parts, and one part leaf mould, with a sixth of silver sand. Mix the soil well, and sift it fine, make the surface smooth, scatter the seeds evenly over the surface, and sprinkle with silver sand lightly. Place the pans in a hotbed, keep the soil moist, and when the plants are large enough to handle prick them off singly about an inch apart in pots or pans. Continue the plants in the hotbed, and when they meet pot them off singly in 3-inch pots; at the end of May remove them to a cold frame, gradually harden them off, and finally plant out in June, or when they are bushy plants. They may flower in autumn, but will be of no use for flower garden purposes. Could you not now procure cuttings of some neighbour? They would strike freely in gentle heat, and be good plants by bedding-out time. It is as much as the seedlings will do to make plants fit for planting out by autumn, and unless you get seed of a good strain it is not worth the trouble of sowing.

Varieties of Grape (——).—You will see by our columns that attention is being drawn to this subject, and we have no doubt that Grape-growers will favour us with their experience; but we do not see what greater information would be secured than we possess already in Dr. Hogg's "Fruit Manual." Neither of the authorities you name grows for fruiting more than half the Grapes described in Messrs. Rivers's catalogue, to which we think you refer, in dividing Grapes into three classes —viz., Muscats, Frontignans, and those not Muscat nor Frontignan. There is no best black or white Muscat suitable for early forcing. As to Frontignans, the White is excellent for early forcing, but is superseded by the Trovéren, and of the Red none is equal to the Red or Grizzly Frontignan for early forcing, though Purple Constantia is good. Frontignans are better suited for early forcing than Muscats, which cannot be well ripened before June or July, but the others may be ripened in May or earlier. Of Grapes neither Muscat nor Frontignan, there is none so good as the Black Hamburgh. Black Champion is good, but not equal to Frankenthal or the old Hamburgh, though in an early vinery we should plant it for its earliness along with both the others. It is very doubtful whether the Early Black Berdeaux will retain its early-ripening properties. Royal Ascot is excellent for early forcing, especially for pot culture. We should include it in an early vinery, for we agree with you that it is well to plant more than one kind, so as to have a succession. Mill Hill Hamburgh, in our opinion the best of all the Hamburghs, requires a higher temperature than the Black Hamburgh and Frankenthal, and ripens a fortnight later. Of the white kinds not Muscats nor Frontignans, Foster's White Seedling must supplant the Royal Muscadine, and of other white kinds Buckland Sweetwater is the best, for though there are some that ripen earlier, as Early White Malvasia, they are so small in berry that it is worth while to wait a few days. With us the White Frontignan is a fortnight earlier than Buckland Sweetwater in the same house. Of grafting kinds for early forcing we have but little experience, but we have no doubt it tends to cause earlier ripening, for grafting has a tendency to produce that result irrespective of stock, as you will find if you have a Hamburgh grafted on a Hamburgh stock, and another growing on its own roots, the grafted ripening earlier than the non-grafted. For accelerating the ripening, were we to graft at all, we should try Duc de Magenta, a vigorous grower, ripening several days earlier than the Hamburgh.

Theophrasta imperialis Cutting Down and Propagation (*E. C.*).—As you have not room for the plant, there will be no alternative but to cut it down, unless you dispose of it for smaller plants. The best time to cut it down will be the middle of February; afterwards keep it rather dry at the root, but encourage it to break by a brisk heat and moisture. The young ripe shoots may be made into cuttings, which should be inserted singly in small pots filled with sandy peat, surrounding the cutting with silver sand. Plunge the pots in a hotbed, keep moist, and cover the cuttings with a bell-glass or hand-glass, keeping them close and shaded from bright sun. The cuttings may be from 3 to 6 inches in length. Trim off the leaves of the part inserted, and cut transversely below a joint. The cutting will be rooted in about six weeks.

Inarching Vines (*Subscriber*).—The best time to do this is after the stock has made shoots a few inches long. There are then leaves to appropriate the sap, and with them there is nothing to fear from bleeding. The operation should be performed near the bottom of the rafter, choosing a smooth part of the stock there, or as near its base as possible. Take from the stock a slice of bark and wood about 1½ inch long, and an equal portion from the scion, and in such a manner that the cuts fit exactly; then make a downward cut in the stock about three-quarters of an inch long and half an inch deep, and a corresponding cut upwards in the scion, and about half or three-parts through. Introduce the cut or tongue of the scion into that of the stock, and so unite them that the bark of both may fit exactly, if not on both, at least on one of the sides. Bind firmly with a ligature of cotton or bast matting, and cover with grafting wax so as to exclude air. A little clay will answer, but to keep it from cracking it should be covered with a little moss lightly secured with matting. You may inarch on the wood of last year, or that of several years' growth, or you may operate on the present year's wood after it has become rather firm, yet quite green or unripe. In about six weeks the union will be complete, then cut away the part of the stock above the scion, and detach the scion from its parent, but make sure that the union is complete. The ligature will need to be loosened when the union is effected; you will notice this from the increased growth of the scion Replace it, but loosely.

Evergreen Hedge for Garden (*C. N. B.*).—The quickest-growing and cheapest is evergreen Privet. If for a boundary fence, Privet will not be formidable enough; in that case plant two evergreen Privets, and four Thorns or Quicks per yard Berberis Darwinii and Thorn make a beautiful hedge—two plants of the Berberis and four of Thorn per yard.

Select Amaryllis—Eucharis amazonica Culture (*A Lover of Flowers*).—Meteor, Rosalind, Jupitar, Reticulata, Victoria, and Amazon have crimson, white and red, scarlet, and white and crimson-striped flowers, and are very beautiful. They require stove treatment, and if obtained now they should be plunged in a gentle hotbed, or failing that be placed in the warmest part of the house, and they will flower in May. After flowering encourage a good leaf growth by an abundant supply of water and moisture, and when it is made afford water only to keep the leaves from flagging, giving the plants a light position. From September to February they may be kept on a shelf in the stove. Eucharis amazonica, we presume you now keep dry, giving but little water. When it begins to grow water freely, and afford plenty of moisture. When good growth has been made, or after July, keep it but moderately supplied with water, and place it in a light airy position in the greenhouse, and in September remove it to a light position in the stove. If it do not throw up flowers keep it dry over the winter, and it will throw up its spikes in spring or early in summer. The main point to be attended to is to secure a good growth, then ripen it well by exposure to light and air. Afford it a season of rest, and when it is introduced to heat the flower-spikes will be thrown up.

Growing Onions (*A Lover of our Journal*).—There may be different means of attaining results, and in growing Onions there are the plan adopted by your gardener and that which you describe. Good Onions are grown both ways. One is as good as the other. We prefer sowing them in beds 4 feet wide, with 1-foot alleys between, sowing in drills about 6 inches apart. The alleys afford ready access to the beds for weeding and thinning, without in wet weather treading on the beds. The main points, however, are to have ground well dug and manured in autumn, to turn the ground over in dry weather, in spring to dress with lime and soot, or charcoal, to keep off grubs (lightly pointing-in these materials), to tread the ground firm, and to sow as early in March as the ground is in good working order. Keep the plants clear of weeds, and then thin out before they become crowded. Those mattere attended to, it is little consequence whether Onions are sown in beds, or in drills continuously without alleys.

Holly Hedge Neglected (*T. H.*).—Unless you can bring some of the smaller branches down, or lay them into the thin parts, you have but a small chance of making a 12 to 14-feet Holly hedge of any use against cattle. We would, however, lay-in as many of the small branches as possible, and then take off the top to 4 feet. We would leave a few of the Thorns and Hollies having the best heads. They are very ornamental, and if not more frequent than 20 yards apart, would not interfere with the growth of the hedge. The best time to cut the hedge down would be at the end of March.

Disa grandiflora Vigorous (*Amateur*).—We have no doubt that your very vigorous plant will reward you next summer with flowers. We

should say it is in a good state of health. The difficulty is to keep it long healthy, especially after it flowers.

Asphalte Walks (*A Lady*).—There is no objection to asphalte garden walks except their colour, if they are quite hard in warm weather. The Company you inquire about is the Val de Travers Asphalte Company, Leadenhall Street, London, E.C.

Box Hedge Straggling (*M. G.*).—Your only plan will be to cut it well in this spring, clipping with the shears, which may be done to any extent but as you do not wish for greater height, we would confine the cutting to the sides, merely removing any straggling growths at the top, so as to promote uniformity of growth. It is well not to prune or clip too early. From the middle of April to the end of May is a good time, but the work may safely be done after the Box begins growth.

Raising Herbaceous Plants from Seed (*Idem*).—As you wish for plants for sale, it will be necessary to grow the most popular kinds. They may be sown in May in the open ground, in rich light soil, watering in dry weather, and when large enough to handle prick them off about 3 inches apart:—Alyssum saxatile compactum, Anemone coronaria varieties, Antirrhinum varieties, Aquilegia vulgaris varieties, A. vulgaris caryophylloides varieties, Arabis alpina, Auriculas, Double Daisy, Canterbury Bells, Delphinium formosum, Double Feverfew, Gentiana acaulis, Geum coccineum, Pansies (for spring flowering sow in July), Hollyhocks, Musk, Myosotis sylvatica, blue, rose, and white; Pentstemons, Phlox decussata, Pinks, Carnations, Picotees, Polyanthuses, Rockets, Brompton and Intermediate Stocks (sow the middle of July), Sweet Williams and Wallflowers. Red lead will not injure vegetable seeds, and it effectually protects them from birds, mice, and rats. The last did us great mischief in the past year, until we coated the seeds with red lead before sowing.

Names of Fruits (*Rev. C. Badham*).—1, Reinette Blanche d'Espagne; 2, Northern Spy; 3, Foulden Pearmain.

POULTRY, BEE, AND PIGEON CHRONICLE.

RESULTS OF POULTRY-KEEPING.

It is often said that comparisons are odious, and to those who cannot bear to take the inferior place they certainly are so, but I should be glad if any of your readers would favour me with their experiences on the following statement, as I might then either learn in what way others have been more successful, or be the means of affording information to them.

Eggs set	116
Chickens hatched	93, or 63 per cent.
Chickens reared	59, or 41 per cent.

Of these thirty-five were cocks and twenty-four hens.—W. H.

ABERDEEN POULTRY AND PIGEON SHOW.

(*From a Correspondent.*)

This again maintained its position as one of the leading exhibitions in the northern part of the kingdom. The entries were more numerous than on any previous occasion, and the quality of the stock exhibited has rarely been equalled. Of the arrangements I can only say that they were well matured by an efficient committee, and faithfully carried out by an active secretary and assistants.

Game.—The class for single cocks was represented by twenty-five birds of rare excellence, many of them having gained first prizes at other shows, and all being fit to win. The single hen class was nearly as good. The cockerels and pullets were by far the best, although some of the unnoticed pens should have been in the prize list. Many good judges thought pen No. 105 should have carried off the cup.

Spanish were scarcely so good as they had been in former years, although many good pens were exhibited. The winning pens were all good, and that which gained the cup changed hands shortly after the Show opened.

Dorkings, as usual, formed the principal classes at this Show; rarely indeed has such a collection been brought together. The Silver-Grey were in many cases heavier than the Coloured, indeed Aberdeen Shows surpass in Silver-Grey Dorkings. Some disappointment was caused with the awards in this class; many of the unnoticed pens should have been in the prize list, our oldest and most experienced breeders being left out in the cold. I was particularly struck with pens 106 and 115 in the cockerel and pullet class being passed over without even a notice. In Coloured Dorkings the Judge was more at home, and seemed to prefer them, having given the cup for the best pen of Dorkings to the first-prize cockerel and pullet.

Cochin-Chinas seem to be falling back in the north; the birds exhibited this year were far behind the specimens we were accustomed to look upon at the former shows of this Club. The prize pens were well placed. Some would have preferred the third-prize cock in the place of the first, and I think they should have changed places.

Brahma Pootras were a large and good class, many of the birds reminding me of the specimens exhibited in the days when Mr. Boyle was so successful. I was not satisfied with the awards in this class, the Judge evidently preferring rough and large birds to those of better shape and marking. The cup hens well deserved their place, and were the best pair of hens exhibited in Aberdeen since Mr. Boyle competed some six years ago.

Houdans were a fair class, and seem to make way a little. I cannot say but I would have awarded the prizes differently. Pen No. 200 ought surely to have been in the prize list. Perhaps the Judge thinks the light-coloured variety inferior to the dark.

Hamburghs are falling back in the north. With the exception of the prize pens nothing deserves especial mention; the Golden-pencilled were the best, and the cup hens the best in their class.

Bantams.—Game mustered more strongly than ever, no less than thirty Bantam cocks competing for the prizes; the Judge must have had much difficulty in deciding where all were so good. The cup in this class was carried off by a remarkable bird. In the class for Any variety of Bantams, with the exception of the winning pens there was nothing calling for special notice.

Ducks, both Aylesbury and Rouen, were well represented, although I have seen better specimens at former shows. I think the Committee should offer a cup at their next show, which would doubtless bring a better competition.

Turkeys and *Geese* were well represented; although not numerous there were some rare specimens exhibited.

The Selling Class comprised many fine birds, which, on the opening of the Show, were speedily claimed.

PIGEONS.

The Pigeon section formed the best and most attractive portion of the Show, such a collection never having been seen so far north, there being 250 entries. It is to be regretted that the birds of Mr. Horner, of Harewood, arrived too late for judging, from being detained on the railway. They comprised some of the best birds exhibited, and would have been sure to have been in the prize list.

Pouters were exhibited in five classes for cocks and five for hens. The Blues and Blacks were perfection, being all birds which had previously carried off honours at the Crystal Palace and Edinburgh Shows. The cup for the best Ponter was won by Mr. Ure's grand black cock. The class for Reds or Yellows was one of the largest, and contained many fine birds. I think this class was the worst judged in the Show, the best Red cock I have seen this season being placed only third; he certainly ought to have been first, being good in shape and form, and rich in colour. In Whites the best cock in the Show was placed third, and should have changed places with the first. Hens were better judged. The Any-coloured class contained a mongrel-looking set, but birds useful for stock purposes. *Carriers* were not a large show, but some fine specimens particularly noteworthy were exhibited. *Short-faced Tumblers* were a poor class. The fancy for Tumblers does not seem to prosper in the north. *Barbs* were a large and excellent class, the winning pens being birds of great merit, and they will doubtless be heard of again. *Fantails*, which at this Show form always one of the largest classes, were better than usual, the winning pens being almost perfection. I regretted to notice one exhibitor showing two hens (pen 487), which had to be separated during the Show. *Jacobins* were one of the largest classes and contained many fine specimens; here again Mr. Horner's birds were the best, but, being late, could not take their proper place. *Trumpeters* were a good class, the best pens in the kingdom competing. I think the prizes were justly placed. *Turbits* call for no special notice, the winning pens being small and handsome birds. *Owls* formed a large class, and there were some very fine specimens. I think the Whites belonging to Mr. Goddard, of Earlston, should have been first and have carried off the timepiece; they were the most admired in the Show. *Nuns* were a good class, many of them being shown without dressing. Had Mr. Symon done a little tailoring to his third-prize pair he would have doubtless taken a higher place. *Dragoons* were a large and meritorious class, the winning birds at Birmingham and the Crystal Palace competing for the place of honour. *Antwerps* formed a large and attractive class. The Judge did not seem quite at home here; many would have preferred some of the unnoticed pens to the winning birds. Pen 557, passed over without a notice, being out of sight, was the best in the class. The *Variety* class was large, and many rare and valuable specimens were exhibited, the winning pen (Laced Fantails), and which also carried off the timepiece, attracting much attention. The second-prize pen, a pair of Damascenes imported from Constantinople, was also much admired. The *Selling* class consisted of twenty-five entries, and birds worth twice the price at which they were entered speedily found buyers.

The Show was well patronised during the two days it remained open, and I was glad to observe a larger number than usual of the pens ticketed "Sold." The names of the Judges and the list of awards were given last week.

Silver Cups at the Crystal Palace Canary Show.—The Lizard and London Fancy cups are already subscribed for, and I should like all intending subscribers to send at once, as the time is now so very short. Cinnamons, I am afraid, this year will be left out in the cold; nobody will give to this class. I hope to send the cups to the Palace on Thursday the 9th inst.—Howarth Ashton, *Polefield Hall, Manchester*.

The Light Brahma Cup at Portsmouth.—I have much pleasure in announcing that since my last letter appeared in your columns I have received some additional subscriptions towards the cup for Light Brahmas, and that the amount promised or paid has reached six guineas; the prize will therefore be a valuable one, and I can only express a hope that the competition will be close, and that the best pen may win. The following ladies and gentlemen have been contributors—Mrs. Williamson, Mrs. Turner Turner, Miss Hales; Messrs.

Crowley, Crook, Leno, Long, Maynard, Pares, Rodbard, Rid'ey and Storer. The contributions have varied from 5*s.* to 10*s.* 6*d.*, and I may add that I have received scarcely any refusals so far in the subscription.—JOHN PARES, *Postford, Guildford.*

LOWESTOFT POULTRY SHOW.

THE Lowestoft Poultry Society held their fourth Show in the Town Hall, on the 25th and 26th ult. The entries had increased so much that the Committee had to purchase a quantity of new pens, even though they refused a number of entries that arrived late. Many of the birds that had already carried off honours put in an appearance, and added another cup to the honours already obtained by their fortunate owners. The birds were well cared for; some of the Committee were always in the room giving their personal attention to the feeding, &c., of the birds. Extra prizes were awarded in all classes where the entries were large, showing the desire of the Committee to gratify the exhibitors as much as possible. The entries had more than doubled since the last Show held in the Town Hall, consequently the space for visitors was very much curtailed.

In the *Game* class the cup went to a grand pen of Brown Reds, although the Duckwings belonging to the same exhibitor were worthy of equal honour. In this class a roupy cock was sent, but the Committee returned it to the owner. There were several other pens worthy of a prize. The cup pen of *Dorkings* was a good, balanced pen, the hen a very square bird, the cock quite equal, with good feet. Mr. James's well-known pen carried off the *Spanish* cup. Had it not been for the careful attention given by the Committee to the cock bird, feeding him with bread and milk, egg, &c., he would not have held up to the end of the Show. Pen 30 consisted of very good birds, the cock's comb rather falling. The hen in the cup *Cochin* pen was decidedly the finest hen in the class, but I would prefer the cock in pen 39, a bird I should like to have seen in the prize list. In the Brahma class I thought the second-prize hen better than the cup bird, but the birds were not so well matched. Pen 57 contained a good cock, but the hen was not equally good. There was a good show of *Hamburghs*. The cup went to a pen of Silver-spangles, the hen one of the best I have seen for some time, and the cock with a beautiful clear tail. The second-prize birds were good, the cock rather faulty in hackle. There was a sharp competition in the class for Golden-pencilled. Pen 65, unnoticed, ought certainly to have had the first prize in preference to the cock with odd sickles. Several other pens were worthy of a better place than they obtained. The Silver-pencilled were a poor class; nothing worth notice, saving the first-prize pen. The Golden-spangled were well shown and fairly placed in the prize list. The second-prize pen contained by far the best hen in the class. In the Variety class La Flèche were first, Silver Polands second, Black Hamburgh third. The Selling class numbered seventy-one pens. Spanish and White Cochins took the first prizes, Brown Red Game and Spanish the second, Cochins and Silver-spangled Hamburghs the third. The two classes of *Bantams* numbered sixty pens. The cup went to a beautiful pen of Gold-laced; the prizes in the Game class went to Duckwings and Black Reds. There were some fine pens of *Ducks*, both Aylesbury and Rouen, and an extra prize was given to a very beautiful pen of Mandarins.

There was a good show of *Pigeons*, the Carriers, numbering forty-one pens, were a show in themselves. Pen 265, highly commended, was decidedly the best bird in the cock class, and was worthy of the first prize. The first and second-prize birds were very good in eye, but rather short in neck. Many of the other pens were filled by very fine birds. Pen 269 contained a long-necked bird of good carriage, but too young to compete with the winners. The hens were well judged. The first prize went to a grand hen with a perfect eye, the second had a very good eye, but was too short in the neck; the extra-prize pen was better in carriage, but not so good in eye. Pen 280 contained a hen with a beautiful head, with cere too red. Although four prizes were given in the Young Bird class, yet there were several other pens that were worthy of prizes. The first prize was well adjudged, going to a grand young cock; the second was a mistake, pen 293, a good hen, ought to have had it; not another bird in the class, except the first-prize bird, could touch her either in eyes or neck. The others were fairly judged. The Pouter entries were small, and, beyond the prize pens, there was nothing of particular note, and not a single Blue was shown. The Short-faced Tumblers were all good in beak and head, some of the pens not well matched. All the prizes went to Almonds. In the Long-faced class a very nice pair of Black Balds took first, and Yellow Beards second. A very good pair of Short-faced Blues were entered in the wrong class. The first prize for old Barbs went to Black, with very good eyes and skulls; the second-prize cock was good, but like those in several of the other pens, the hen was not equal to the cock. Several very good pens of young Barbs were shown; both prizes went to Blacks; the second-prize pen was soon claimed. The winning Fantails carried their tails well. The cock in the second-prize pen was the best bird in the class. The first-prize Antwerps were good, the others only of average merit. The Variety class contained some beautiful birds. A fine pair of Black Trumpeters, with perfect rose, took the first prize. An extra first prize went to a pair of Yellow Dragoons, coarse in skull, and the hen had in colour on the thigh and rump. Blue Runts were second, and a very good pair of Magpies extra second. Many other pens were worthy of especial note. In the Selling class a pair of White Florentines were first. The question is sometimes put, What is there in a name? Anyone looking over the new varieties of Pigeons would be convinced there is a great deal in a name, for in some of the new specimens certainly there is nothing but the name to attract attention. Florentines are a striking instance; one would be inclined to class them as inferior Runts were it not for the exhibitor having the name properly entered in the catalogue. The point cup for Pigeons was awarded to Mr. P. H. Jones.

GAME (Any variety).—Cup and 2, S. Matthew, Stowmarket (Black Reds and Duckwings). Local, T. Sterry, Lowestoft (Black Red). *hc*, W. Boyes, Beverley; R. Hall, Cambridge (Black Red and Duckwing). *c*, Rev. C. Gilbert, Burlingham.

DORKINGS (Any variety).—Cup, L. Patton, Hillmore, Taunton. 2, F. Parlett, Great Baddow (Coloured). Local, (4. W. D. Palmer, Lowestoft. *c*, Mrs. E. Wheatley, Ingatestone; J. Frost, Parham (Coloured); Henry Lingwood, Barking, Needham Market.

SPANISH.—Cup, F. James, Peckham. 2, Howard & Nicholls, Peckham. Local, W. Saunders, Lowestoft. *hc*, W. Saunders; J. K. Fowler, Aylesbury.

COCHIN-CHINA (Any variety).—Cup, Henry Lingwood (Buff). 2, Horace Lingwood, Creeting (Partridge). Local, J. Ling, Lowestoft (Partridge). *hc*, Lady Gwydyr, Stoke Park, Ipswich; J. Dutton, Ipswich (Buff); T. Rogers, Walsall. *c*, J. Watts, King's Heath (Buff).

BRAHMA POOTRA (Any variety).—Cup, Lady Gwydyr. 2, W. Adams, Ipswich (Dark). Extra, Horace Lingwood (Dark). Local, A. Page, jun., Lowestoft (Dark). *hc*, J. K. Fowler. *c*, Rev. J. Richardson, Sandy (Dark); A. Page, jun. (Dark).

HAMBURGHS.—*Golden-pencilled.*—1 and 2, W. K. Tickner, Ipswich. Local, E. P. Youell. *c*, Rev. J. Richardson; R. R. Parker, Ipswich; J. K. Fowler. *Silver-pencilled.*—1, H. Pickles, jun., Earby. *Golden-spangled.*—1, H. Pickles, jun. 2 and Local, L. Wren, Lowestoft. *c*, Miss C. E. Palmer, Lighthorne, Warwick. *Silver-spangled.*—1 and Cup and Local, J. B. Bly, Lowestoft. 2, Rev. F. Tearle. *c*, H. Pickles, jun.; J. W. Ling, Lowestoft.

ANY OTHER VARIETY, EXCEPT BANTAMS.—1, W. Burrows, Diss (La Flèche). 2, H. Pickles, jun (Silver Polands). Extra, J. Watts (Black Hamburgh). Local, Rev. A. Gilbert (Crève Cœurs). *c*, W. K. Patrick, West Winch, Lynn (Polands) (2); Rev. C. Gilbert (Houdan); Rev. N. J. Ridley, Newbury (Malay); C. Maggs, Melksham (Black Hamburgh); J. K. Fowler (French).

SELLING CLASS.—*Cock or Cockerel.*—1, F. James (Spanish). 2, H. E. Martin, Sculthorpe (Brown Red Game). Extra, T. Rogers (Cochin-China). Local, Mrs. C. Denton, Lowestoft (Spanish). *hc*, Howard & Nicholls. *c*, G. P. Rouse, Fakenham (Game). *Hens or Pullets.*—1, S. Felgate, Ipswich (White Cochins). 2, Howard & Nicholls. Extra, Rev. F. Tearle, Gazeley Vicarage, Newmarket (Silver-spangled Hamburgh). Local, L. Wren (Golden-spangled Hamburgh). *hc*, Rev. T. C. Hose, Roydon Rectory (Buff Cochins); J. Dutton (Buff Cochins); H. Brown, Putney Heath (Spanish); R. R. Parker (Black Red Bantams). *c*, H. Pickles, jun. (Polands).

GAME BANTAMS (Any variety).—1, Rev. F. Cooper, Ampney Crucis (Duckwing). Extra 1, W. Adams (Black Red). 2, H. W. Wallace, Framlingham (Black Red). Extra 2 and *hc*, Hon. Mrs. Paget, Hoxne, Scole (Duckwing and Black Reds). Local, J. F. S. L. Barber, Lowestoft (Black Red).

BANTAMS (Any other variety).—1 and Cup, Rev. G. F. Hodson, North Petherton. 2, M. Leno, Markyate Street (Laced). Extra, C. Drake, Stoke, Ipswich (Black). Local, Miss M. Jodrell, Lowestoft (Japanese). *hc*, Rev. F. Tearle (White). *c*, J. Watts (Sebrights).

DUCKS.—*Aylesbury.*—1, Lady Gwydyr. 2, J. K. Fowler. Local, F. B. Potts, Kessingland, Lowestoft. *hc*, Lady Gwydyr. *Any other Variety.*—1, Mrs. E. Wheatley (Rouen). Extra 1, M. Leno (Carolina). 2, J. K. Fowler (Rouen). Local, Rev. A. Gilbert (Musk).

PIGEONS.

CARRIERS.—*Cock.*—1, W. H. Mitchell, Moseley, Birmingham. 2, H. Yardley, Birmingham. Extra, F. Smith, Selly Oak, Birmingham. Local, L. Wren. *hc*, E. Mayston, Diss (Dun); W. Massey, Spalding; F. W. Metcalf, Cambridge. *c*, P. H. Jones; F. W. Metcalf. *Hen.*—1, F. Smith. 2, F. W. Metcalf. Extra, W. Massey. Local, L. Wren. *hc*, P. H. Jones, Fulham; H. Yardley; F. W. Metcalf; W. H. Mitchell. (Any variety).—*Chickens.*—1, W. Massey. 2, W. H. Mitchell. Extra, F. Smith. Local, L. Wren. *hc*, W. Massey; F. W. Metcalf (2); L. Wren. *c*, J. Watts (Black).

POUTERS.—*Cocks.*—1, J. Walker, Newark. 2, W. Nottage, Northampton. *Hen.*—1, P. H. Jones. 2, W. Nottage.

TUMBLERS.—*Short-faced.*—1, J. Ford, Monkwell Street, London. 2, H. Yardley. *hc*, P. H. Jones (2); W. J. Woodhouse, West Winch, Lynn; J. Ford. *Any other Variety.*—1, W. J. Woodhouse (Baldheads). 2 and Local, Misses E. and A. Wren (Yellow Beards).

BARBS.—1, F. Smith. 2, P. H. Jones. Local, D. Bedford, Lowestoft. *hc*, H. Cawood, Thorne; H. Yardley; P. H. Jones. *c*, E. Mayston. *Chickens.*—1, P. H. Jones. 2, J. Watts. Local, D. Bedford. *hc*, W. Massey; W. Nottage; P. H. Jones. *c*, J. Holmes, Lower Sydenham.

FANTAILS.—1, H. Yardley. 2, A. A. Vander Meersch, Perry Hill. Local, F. S. Worthington, Lowestoft. *hc*, P. H. Jones; J. Walker.

ANTWERPS.—1, W. H. Mitchell. 2, J. Watts. Local, D. Bedford. *hc*, H. Yardley.

ANY OTHER VARIETY.—1 and 2, P. H. Jones (Trumpeters and Jacobins). Extra 1, H. Lyon, Ipswich (Yellow Dragoons). Extra 2, A. A. Vander Meersch. Local, A. W. Wren (Yellow Dragoons). *hc*, H. Yardley; P. H. Jones (Magpies); W. Bearpark, Ainderby Steeple; C. Norman, Ipswich (White Trumpeters). *c*, E. Mayston (Black Runts); Hon. Mrs. Paget (Starlings and Spots); H. Yardley; E. M. L. Cocksedge, Bury St. Edmunds (Archangels); W. Nottage (White Dragoons and Blue Owls); A. W. Wren, Lowestoft (Yellow Dragoons); J. Watts (Swallows).

SELLING CLASS.—1, P. H. Jones (Fantails). 2, H. Yardley. Local, A. W. Wren (Yellow Dragoons). *c*, E. Mayston (White Dragoons); P. H. Jones (Barbs); W. Nottage; A. W. Wren (Yellow Dragoons); J. F. Loversidge (Fantails); J. Ford (Carriers).

JUDGES: Rev. T. L. Fellowes, Honingham Rectory, Norwich, and Mr. W. B. Tegetmeier.

BARROW POULTRY SHOW.

THE following are the awards made at this Show, held on January 27th and 28th:—

GAME.—*Cock.*—Cup, W. Boyes, Beverley. 2 and 3, C. W. Brierley, Middleton, Manchester. *hc*, J. Frith, Chatsworth; J. H. Wilson, St. Bees. *Cockerel.*—Cup, J. Mason, Green Ayre, Lancaster. 2, J. H. Wilson. *hc*, W. Grice, Bootle. *c*, J. Wilson, Beckermont; J. Mashiter, Ulverston. *Pullets.*—1 and 2, C. W. Brierley. *hc*, W. Boulton, Dalton-in-Furness; W. R. Ormandy, Barrow; J. H. Wilson; J. Mashiter.

GAME.—*Black-breasted and other Reds.*—1, C. W. Brierley. 2, T. Mason. *hc*, J. Hodgson, Sheffield; W. Boyes; J. Frith; J. H. Wilson. *Duckwings and other Greys and Blues.*—1, W. Boyes (Duckwings). 2, J. H. Wilson. *hc*, J. Frith (Duckwings); J. Mashiter; R. Casson, Ulverston. *Any other Variety.*—1, C. W. Brierley. 2, J. Frith. *hc*, T. Mason (Pile). *Pullets.*—1, W. Boulton (Brown Red). 2, C. W. Brierley. *hc*, T. Mason.

GAME BANTAM.—*Cock.*—1, G. Hall, Kendal. 2, J. Mashiter. *hc*, J. R. Robinson, Sunderland; W. Grice; J. Hunt, Barrow.

SPANISH (Black).—1, C. W. Brierley. 2, H. Beldon. *hc*, Burch & Boulter, Sheffield; J. T. Hudson, Ulverston; J. Thresh, Bradford.
DORKINGS.—1, J. White, Warlaby, Northallerton (Grey). 2, S. H. Stott, Rochdale. *hc*, R. D. Holt, Orrest Head. *c*, R. D. Holt; H. Beldon.
COCUIN-CHINA—*Cinnamon and Buff.*—1, Mrs. Wilkin, Bootle. 2, J. Sichel, Timperley (Buff). *hc*, T. Stretch, Ormskirk; W. Burnell (Buff); J. Sichel (Buff). *Brown and Partridge.*—1, J. White, Whitby, Wakefield (Partridge). 2, E. Leech, Rochdale. *hc*, T. Stretch (Partridge). *White.*—1 and 2, J. Sichel. *hc*, J. Weeks, Bootle; E. Fearon (2). *c*, J. Cowman, Whitehaven.
BRAHMA POOTRA.—1, E. Leech. 2, J. Sichel. *hc*, H. Lacy, Hebden Bridge; J. Cowman; H. Butler, Bradford; W. G. Mulligan; H. Beldon.
HAMBURGHS.—*Golden-pencilled.*—1, H. Pickles, jun., Earby. 2, H. Beldon. *Silver-pencilled.*—1 and 2, H. Pickles. *hc*, H. Beldon. *c*, W. M. Mann, Kendal. *Golden-spangled.*—1, J. Ogden, Hollinwood. 2, H. Beldon. *hc*, J. Buckley, Taunton, Ashton-under-Lyne. *Silver-spangled.*—1, Ashton & Booth, Mottram. 2, A. Ainslie, Ulverston. *hc*, H. Beldon.
BANTAMS.—*Game.*—1, G. Hall. 2, J. W. Brockbank, Kirksanton. *hc*, J. R. Robinson; J. Sichel; G. Maplee, jun., Wavertree, Liverpool; J. Mashiter. *c*, J. Whitham, Barrow. *Any other Variety.*—1, M. Leno (Laced). 2, J. Sichel (Pekin). *hc*, H. Yardley; M. Leno (Laced); S. & R. Ashton, Mottram (Black); H. Beldon; H. Picklee, jun. (Black).
GEESE.—1, E. Leech. 2, S. H. Stott. *hc*, E. Leech; J. Hunt. *c*, R. B. Hudson; T. C. Hunter, Ulverston.
DUCKS.—*White Aylesbury.*—1, E. Leech. 2, S. H. Stott. *hc*, E. Fearon; J. Hunt. *Rouen.*—1, W. Gamon. 2, W. G. Mulligan. *hc*, A. Dickinson; G. Porter; J. White; S. H. Stott. *East Indian.*—1 and *hc*, S. Burn. 2, Rev. W. Sergeantson. *Any other Variety.*—1, S. Burn. 2, C. W. Brierley. *hc*, S. Burn; Rev. W. Sergeantson; M. Leno (Mandarin and Carolina); S. H. Stott (Carolina); W. Silvester (Carolina); H. B. Smith (Shieldrake and Carolinas).
ANY OTHER VARIETY.—1, H. Beldon. 2, J. Sichel (French). *hc*, W. G. Mulligan (Scotch-Greys); Rev. W. Sergeantson, Acton Burnell (Black Hamburghs); N. J. Ridley, Newbury (Malay); H. Pickles, jun. (Polands); W. Silvester, Sheffield (Polands); W. Gamon (Polish); Mrs. Wilkin (Houdans).
SELLING CLASS.—1 and 4, F. H. Green, Belfast (Brahmas). 2, H. Beldon, Golstock. 3, W. Boulton (Brown Red). *hc*, E. Wadham, Millwood, Dalton (Buff Cochins); E. Hall, Brimington, Chesterfield (Duckwings); J. Cowman (Brahma); W. Grice (Black Red Game); W. G. Mulligan, Springfield, Belfast (Spanish); M. Leno, Markyate Street (Light Brahma); W. Masland, Milverton (Cochin); C. W. Brierley; W. A. Burnell, Southwell, Notts; J. & J. Tyson, Barrow (Brown Red); T. Jackson, Birkenhead (Silver Polands); J. Mashiter (White Cochins); E. Fearon, Whitehaven; W. Gamen, Chester (Polish) (2). *c*, H. Andrewe (Brahma Pootra).

PIGEONS.

CARRIERS.—1 and 2, E. Horner, Harewood, Leeds. *hc*, H. Yardley, Birmingham; J. Smith, Ulverston; R. Lomas, Dalton; W. H. Mitchell; J. & W. Towerson, Egremont.
POUTERS.—1, E. Horner. 2, J. & W. Towerson. *hc*, J. Smith; J. & W. Towerson.
TUMBLERS (Any variety).—1, J. & W. Towerson. 2, W. Boulton. *hc*, H. Beldon.
JACOBINS.—1, J. W. Edge, Birmingham. 2, J. & W. Towerson. *hc*, E. Horner.
ANTWERPS.—1, T. Cock, Lancaster. 2, H. Yardley. *hc*, W. Arkwright; T. Cock; E. Horner; W. H. Mitchell, Moseley, Birmingham (2).
BARBS.—1, H. Yardley. 2, E. Horner. *hc*, E. Moreton, Hindpool, Barrow.
TURBITS.—1, H. Yardley. 2, E. Horner. *hc*, J. W. Edge.
OWLS.—1, H. Beldon. 2, J. Smith. *hc*, J. Canby, Hindpool, Barrow; J. Chadwick, Bolton; J. & W. Towerson.
FANTAILS.—1, E. Horner. 2, J. W. Edge. *hc*, J. F. Loversidge, Newark; H. Beldon.
DRAGOONS.—1, F. Graham, Birkenhead. 2, W. H. Mitchell. *hc*, G. Goore, Aigburth, Liverpool; J. Chadwick; E. Horner.
TRUMPETERS.—1, E. Horner. 2, J. & W. Towerson. *hc*, J. Smith (2); H. Beldon.
RUNTS.—1, J. Fisher, Barrow. 2 and *hc*, H. Yardley.
ANY OTHER VARIETY.—1, H. Beldon. 2, E. Horner. *hc*, H. Yardley; J. Smith (2).

CANARIES.

BELGIAN.—*Yellow.*—1 and *hc*, J. Hunt. 2, W. Jones. *c*, J. N. Harrison. *Buff.*—1, J. Hunt. 2, W. Crewdson. *hc*, J. Moffatt. *c*, J. N. Harrison.
MULE.—1, W. J. Stewart. 2, W. Bradley. *hc*, W. Arkwright. *c*, J. T. Mount.
PIEBALD.—*Yellow or Buff.*—1 and *c*, W. Jones. 2, W. J. Stewart (Buff). *hc*, J. N. Harrison.
LIZARD.—*Gold and Silver-spangled.*—1, J. W. Martindale. 2, W. J. Stewart (Gold-spangled). *hc*, J. N. Harrison. *c*, J. Bolton.
COMMON.—*Yellow.*—1 and *hc*, J. Hill. 2, W. J. Stewart. *c*, J. S. Mount. *Buff.*—1, 2, *hc*, and *c*, J. Hill.
GOLDFINCH.—1 and *hc*, J. N. Harrison. 2, W. Arkwright. *c*, A. Ainslie.

RABBITS.—1 and 2, W. Arkwright, Sutton Scarsdale (White Buck and Doe). *hc*, J. Boyle, jun., Blackburn (Himalayan Buck); J. A. Richardson, Lancaster. *c*, J. A. Richardson.

JUDGES.—*Poultry:* Mr. E. Hewitt, Birmingham. *Pigeons:* Mr. S. Handley, Pendleton. *Canaries:* Mr. A. Benson, Whitehaven.

COLCHESTER SHOW RABBIT PRIZES.

IN common with many others I was surprised to read Mr. M. Millington's letter in last week's number, in which he failed, as I am able to show, to prove that the prizes for Rabbits are wrongly arranged. In the first place, I am not afraid of contradiction if I say that the foreign varieties are at the present time more popular than the Lop-ears, as I can prove by the York Show itself. It is quite true that a sum of only £3 is given to Lops, and £9 to the six different varieties of fancy Rabbits, at Colchester, and even then Lops receive the greater share. I will analyse the prize list and entries of the York Show to prove that Mr. Millington cannot maintain that the Colchester prize-money is not fairly divided. In Classes 74 and 75 the value of prizes, including the cup, was £7 5*s.*; entries for both classes 23. Classes 76, 77, and 78 had prizes value £8 15*s.*, and only 22 entries. These five classes were for Lop-eared. Now, for the fancy variety classes; there were three classes—79, 80, and 81, and £3 15*s.* and a silver medal as prizes, and yet there were 45 entries. Thus the Lop-ears had more than four-fifths of the amount offered for the eight classes, but still only an equal number of entries. In the Selling Class there were more Lop-ears than any other breed, thus proving that they are at a discount if compared with the other kinds, because they are exhibited for sale.

I think the Colchester Committee has learnt a lesson by the York Show, and framed their schedule accordingly. Mr. Millington may think everything of Lops, and nothing of any other breed, but that is no reason why they should not be encouraged. Everyone admits the success of the York Show, but even its Committee will, no doubt, make a fresh distribution of prizes at any future show. I cannot, and I write impartially, see how the Colchester schedule is inferior to the Portsmouth one; however, time will prove. Mr. Millington's suggestion as to the formation of a co-operative Rabbit Club would entail too much trouble without affording any definite benefit to the Rabbit fancy.—D. P. GOODING, *Colchester.*

THE MANAGEMENT OF BEES DURING SNOW.

THERE is no time during the whole year that bees require more care than during winter. Although, comparatively speaking, it is a time of rest with the apiarian, his charges still must be looked after, their wants supplied, and means which ought to be prepared for every emergency during autumn applied for their preservation, as it is only by this care in winter that success in summer can be expected. As winter management has been so often described in these pages, it is not necessary to enter into details, and I will therefore confine myself to a few remarks on the preservation of bees during snow. Your correspondent "R. S." very wisely considers shading the best means yet devised; but even this plan is far from being entirely satisfactory, because shading will not reduce the temperature, which as a rule rises after snow, and causes the bees to seek an airing outside. When they do this, shade does more harm than good; it mars the bees when returning to their hive, and very many fall to rise no more. The only time when bees are in danger of losing themselves in snow is from the end of January to the end of March. The worst time that we have to contend with is at the termination of a long frost when deep snow has been lying, which commonly occurs from the end of January to the middle of February; and when the thaw comes in a calm with insufficient wind to lift the snow, the bees, roused by the sudden rise of temperature, make a rush, and thousands fall on the still cold snow to perish. It is recommended in the "Handy Book of Bees" to shut them in in time of snow; where this advice is taken it will prove sure destruction to the bees. Far better would it be to let them alone.

It is, moreover, recommended in the same book to tame vicious bees by placing a "scarecrow or potato bogle" in front of the hive. I cannot help remarking that this is far more like imagination than reality. The great Creator has made these our favourites much too perfect, and their senses, of which we have but a faint conception, far too acute, to be so deceived as to mistake a "potato bogle" for a man. Some people declare that it is not necessary to have any idea of the natural history of bees in order to manage them successfully. It is true that many keep and are very successful with bees who know very little about their habits and natural history; but apart from this, it is highly necessary, in the case of any animal whatever, to have a perfect knowledge of its natural history if we would cultivate it successfully. It is particularly desirable then during winter, and whilst snow is on the ground, to assist bees in accordance with their nature, and by so doing to preserve their lives, which is then the great aim—not by shading, as that is only a partial remedy, neither by shutting them in, which means suffocation and death, but by ventilation. Have your hives so made that, whenever snow appears at a time when the days are getting long, the doorway can be instantly closed, and the hive ventilated according to the number of its inmates to such an extent that, instead of the temperature of the hive being raised it shall in fact be reduced, thus keeping the bees quiet and preventing any attempt to get out until the weather is suitable. This is the only plan that I have ever found successful, and I could give an account of its success extending over a series of many years; but, as it is easy to try, I would rather let the experiment speak for itself.—A LANARKSHIRE BEE-KEEPER.

ROOFING FELT AND TAR.

I BEG to state, in answer to "A NORTHUMBERLAND BEE-KEEPER," that I have used both, and I did not see any harm result to the bees. The bee house once was coated when the weather was warm and the bees on the wing; at first they did not like the smell, and would hesitate a little, and then went in. I should recommend its being done in winter time, and not in warm weather, or else the bees would stick fast to the tar, or get their legs and wings smeared over from alighting on the painted part of the sides. The bee house I made holds three hives, with a passage out through the front. The roof, boarded and covered with felt, is sloping to the front, so as to give more room behind for manipulating; the back is closed

with a loose shutter without hinges, having two handles to lift it by, and is painted with gas tar.—J. R. F.

OUR LETTER BOX.

Books (*C. H. B.*).—We know of no work upon Game and Game Bantams exclusively. More relative information will be found by reference to the indexes of our back volumes than in any book hitherto published. (*A Constant Subscriber*).—Brent's "Canary." You can have it free by post if you enclose twenty postage stamps with your address.

Bristol and Clifton Show.—Highly commended, William Perrin, Bristol, should have been Nantwich.

Malay Prizes at Northampton.—"The Committee of the Northampton Poultry Show are deserving of the thanks of breeders and admirers of Malays, for considerately giving them a separate class in the prize list. I shall be happy to subscribe with others towards a cup or sweepstakes, as a special prize for the best Malay cock, hatched in 1870, but my time is too much occupied to admit of correspondence in its behalf. I shall hopefully look forward to the prize lists of the principal shows of this year, trusting to find separate classes at most of them, for Polands, Black Hamburghs, and Malays.—A. G. Brooke, *Shrawardine, Salop.*"

Pullets Eating the Cock's Feathers (*A Sufferer*).—Fowls, like many other bipeds, are apt scholars when the lesson is an evil one. One of the hens, being out of condition, has begun to pick, and the others, seeing blood, have followed her example. It is curious, but cocks of any breed will stand while the hens eat them, especially Spanish, and Dorking cocks will stand with hens pecking their combs on each side till the hens make a hole. You must immediately remove the cocks. Let all the peccant hens be well purged with castor oil, a table-spoonful every other day for three days. Then give turves of grass cut with plenty of mould, and, if you have any, some lettuce. We advise for birds that, being in confinement, have no access to grass. We have never known birds do it that were at full liberty. The cocks may be turned with the hens occasionally, and that is all that is really necessary.

Food for Swans (*C. W. D.*).—Much experience has taught us the best food is the cheapest; we therefore advise either oats or barley, the first for choice. Cygnets should always be fed in severe weather. The proper way to feed them is to put a small tub where they will see it directly, to cover the bottom with a sod of grass, this with oats, and then to cover the whole with water. Much waste is prevented, and it saves the food from the depredations of small birds. It is of course useless to put it anywhere but near the birds, as if uninterrupted it would soon be frozen. If refuse green food can be mixed with the oats so much the better.

Hen's Legs Spasmed (*M. B. D.*).—The spring-halt you mention is a bad symptom in a fowl, but it may exist for a long time without serious danger to health. We think constant meat-feeding injurious, and we believe if you do not discontinue it we shall often have you for a queriist. We should do nothing beyond giving castor oil, a table-spoonful every alternate day for three days.

Turkeys (*M. G.*).—As the Peacock. One visit in the proper season to the cock is sufficient.

White Dorkings (*F. W.*).—We consider the deaf ear almost unimportant, but if we had to choose we would have it red. The white one will probably be transmitted to many of his offspring. The accident of having one claw shorter than the other is of no consequence. It is an accident, as you say he has lost it. It is singular one of his descendants has the same. There is no fear of its being continued. We believe Mr. Martin's address is Claines, near Worcester.

Breeding Black Hamburghs (*W. U.*).—We advise the Spanish hen, if you have but one pen. If you are wise, you will have two and reverse the sexes. We say if you are wise, because you cannot breed perfect cocks and hens from the same parents.

Polands' Crests Dirty (*Aliquis*).—There is little cause to fear dirt in fine weather. The best breeder we ever knew used in damp, dirty, and wet weather to keep the top-knots up and clean by putting indiarubber bands round them. The crests should never be washed unless the birds are going to a show. It should then be carefully done with a sponge, wetting only the outside of the feathers, wiping them dry, and putting the bird in soft straw. Top-knots should never be washed, if it can be avoided. The most ornamental Ducks are Carolinas and Mandarins. They may be had of Messrs. Baily, Mount Street, Grosvenor Square. We do not know their prices.

Cochin-Chinas (*Recent Subscriber*).—Vulture hocks are long feathers growing from the thighs and projecting from the legs in a downward direction. Plucked hocks are those from which these feathers have been pulled. The vulture hock is a great disadvantage, and you are fortunate that your birds have it not. They are a good weight, but might weigh more. Where they are carefully attended to they should make a pound in every month up to 9 or 10 lbs. Get rid of every bird that has any feathers protruding from the knee.

White Feathers in Coloured Dorkings (*An Amateur*).—If your Dorkings belong to the general Grey class, the white flights are not even a disadvantage. Your description is that of very good birds. You may exhibit and safely breed from your pullets. They are not Silver-Greys. These latter must not have a white feather. Silver-Greys are birds of colour, and most difficult to get perfect. Grey may be of any colour except black and white. Dr. Campbell's are Grey birds. A Silver-Grey cock must have a perfectly black breast and tail, without the suspicion of white, very light hackle and saddle, and steeled bar wing. Baily's book on fowls devotes a chapter to Dorkings. It is the best time in the year to set Dorkings, and it would be no advantage to have the house artificially warmed. You may leave the cock with ten hens.

Brahmas Laying Double-yolked Eggs (*C. H. S.*).—A dose or two of castor oil to each of the Brahmas, say a table-spoonful every other night for a week, will put their secretions to rights, and cause two yolks to inhabit two eggs. If they continue dropping them from the perches, remove them; they must then lay on the ground. Is the rubbish to which they have access bricklayers' rubbish? if not, give them some. We can give you no cure for feather-eating. Try to find which is the culprit and remove her. If you can, let them out; they never do it when at liberty. No preparation is necessary to impart the brilliant tint to a Spanish comb. It is natural, and we have now cocks with combs of startling brilliancy. We should never use egg as an outward application to fowls.

Unicomb Hive (*An Amateur Bee-keeper*).—We have forwarded your query to Mr. S. B. Fox, who hopes to reply in our next.

Dysentery in Bees (*J. T. S.*).—Shutting-up your bees and placing the skep with the board underneath, "on the mild part of a greenhouse flue," though it may dry the board and warm the combs which are supposed to be frozen, will, it is to be feared, only aggravate the malady with which the bees are afflicted. Whether they are suffering from dysentery, or the complaint which Mr. Woodbury hypothetically named "dropsy," cannot be determined from the description given; but in either case it is to be remembered, that the diseased bees are surcharged with fluid or fæces, and consequently no cure can avail which does not make them part with their contents. It is very undesirable that they should do so within their hive, and whilst inclement weather lasts they cannot effect it outside in the open air. The cure for dysentery in winter, recommended by Dzierzon, will be found at page 475, of the ninth vol. of the Journal, and is as follows:—"The bees should be brought into a warm room with but one window, and that facing the south. The hive being placed in the sun a few feet from the window, its inhabitants are set in motion by a little food, either inserted within the hive or injected into it. As the bees take wing and fly towards the window many empty themselves, and the rest will do so when they reach and rest on the window-sill. Here the brown fæces must be sponged off as rapidly as they are ejected, lest bees soil themselves with them, and when all have had the required opportunity they will joyfully re-enter their hive, if the entrance be brought close to them." But one more convenient to put in practice, and which has been tried with benefit, is to wait for a mild sunny day when bees can with safety leave their homes. As soon as any are seen going abroad and returning, lift the skep from its resting-board (which will do no harm), and place it upon another that has been well warmed before the fire, and stimulate the bees to flight by administering a small quantity of food. When the board grows cold it may be replaced by the old one which has been cleaned and warmed, and if the process be continued for an hour or so, the lives of the best bees will be saved, and a large majority of worthless ones got rid of. Those bees that cannot fly should be destroyed, their presence amongst healthy ones can do no good and may do much harm. I have sometimes thought if the skep were placed upon a thin board resting on heated sand, that the heat would be retained a long time, and render repeated changing of the floor-board unnecessary; but as the board is liable to get soiled, the frequent changing of it is advantageous, and if this is attended to on the few fine days that occur at intervals during winter and spring, the hive, whether suffering from "dropsy" or dysentery, may ultimately master the complaint.

REMARKS.

25th.—Fine morning; slight snow about noon; clear in evening about 7, cloudy afterwards.

26th.—Very fine bright frosty day; brilliant night.

27th.—Fair; cloudless at night.

28th.—Dull and overcast throughout.

29th.—Dull and overcast throughout.

30th.—Overcast in morning; snow began about 11 A.M., and fell to a total depth of one-tenth of an inch.

31st.—Dull morning; brighter in afternoon; broken clouds in evening snow still lying.

A regular winter week, high barometer, northerly wind, and the mean temperature below freezing point. The 9 A.M. temperatures almost as uniform as last week, but 4·4° lower; the range in the week actually less, or only 10.9°—viz., 25.4° to 36.3°.—G. J. Symons.

COVENT GARDEN MARKET.—February 1.

Trade is somewhat brisker. Good dessert Pears are becoming more scarce. There have been heavy arrivals in the Potato market.

From observations taken near London during forty-three years, the average day temperature of the week is 45.2°, and its night temperature 30.3°. The greatest heat was 65°, on the 10th, 1831; and the lowest cold zero, on the 13th, 1855. The greatest fall of rain was 0.52 inch.

SETTING OF GRAPES.

MR. PEARSON, page 509 of the last volume of this Journal, remarks that it would be interesting if cultivators would state their treatment of Grapes, as he observes some are better growers of particular sorts than others; thus at one place will be found a champion grower of Hamburghs, and at another a champion Muscat grower. I do not call myself either, nor do I grow Grapes on a very extensive scale. The tastes of our employers ought to be the first consideration—some like Muscat-flavoured, others Hamburgh Grapes.

Muscats being our favourite Grape, I have endeavoured to grow them as well as I could, and with a little success. The difficulty I first had to surmount was the setting; this is easily done if attention is paid to drawing a dry hand over that part of the bunch which is in flower, and repeating the operation two or three times a-day until every berry is set. But there are Grapes which task the dry-hand system; two, Mr. Pearson mentions—viz., Canon Hall Muscat and Black Morocco. I will name another—Royal Vineyard. The cause of these three not setting is that "the anthers curl back at the moment the flower opens;" the ends always seem wet.

I have set Black Morocco and Royal Vineyard to a berry. Canon Hall I have not grown. My method is as follows. The hand is charged with pollen from the Muscat of Alexandria in flower at the same time. The hand must be dried at every application, and drawn gently over that part of the bunch in flower. Repeat this twice or thrice a-day until every berry is set. I have set these two so well that it became no easy matter to thin the berries.

I am of the same opinion as Mr. Douglas, that no one should decry a Grape or any other fruit until it has had a fair trial; this I have given the Royal Vineyard, and I have written in these pages about its bad setting and other bad qualities, such as liability to spotting, blotching, &c. I have tried it as a pot Vine, but cannot speak of its goodness when so grown; but I can say it is a good keeper as respects what remains of the bunches, and some like the flavour. On the whole it ought to have a place. I am to retain it.

Muscat Hamburgh [Black Muscat of Alexandria] is a splendid Grape when grafted on the Black Hamburgh. I have had bunches of it weighing 3½ lbs. I have not had it so black as Lady Downe's or Alicante, but in flavour it is far superior to either. Of Muscat of Alexandria I set every berry. I have had bunches 4 lbs. in weight, and berries 1 inch in diameter. Bowood Muscat is so much like it that I cannot see any difference, except that it sets more freely.

I do not place the slightest stress on preserving either a dry or wet atmosphere, apart from the dry-hand system. When my Grapes are in flower the paths and troughs are not full of water. As I grow different sorts in one house, my Hamburghs are all set by the time the Muscats are in flower, the only difference in the treatment is that the Muscats are at the warmest end, less air being given to them throughout; no front air is given until they commence colouring.

As I have already remarked I am not an extensive grower, but I have had early Grapes in April and late ones in February from two houses; perhaps it will not be out of place here to name the sorts I grow. Those in the early house are Muscat of Alexandria, Bowood Muscat, Muscat Hamburgh, Duchess of Buccleuch, Foster's White Seedling, and Black Hamburgh. These are planted inside. I grew last year in pots four on the back wall—viz., one Black Frontignan and three Black Hamburgh; between those in front, standing on the hot-water pipes, were two Lady Downe's and two Alicante Vines. The Black Frontignan was first ripe—on the 24th of April. Those on the back wall were well started in front before being placed against the back wall. In the late house, planted inside, are Muscat of Alexandria at the warmest end, Muscat Hamburgh, Golden Champion (not fruited yet), Madresfield Court (not fruited), Lady Downe's, Mrs. Pince's (not fruited), Royal Vineyard, White Lady Downe's (not fruited), and in pots four Black Frontignan and two Royal Vineyard.

I cut my last Muscat of Alexandria on January 23rd, also Royal Vineyard at the same time. I have eight bunches of Lady Downe's fit to cut now (January 25th); they look as if they would hang a month longer, but I will cut them with a good bit of wood, and if so cut and hung in any dry place they will keep until used up.

If a few notes on the management of borders, &c., will be of any use to an amateur who may want to have Grapes all the year through, or nearly so, with two houses, I will write again. [We hope you will.—Eds]—C. M. McCrow, *Nash Court, Faversham.*

PLANT CULTURE IN GLASS HOUSES.

Few sights in a garden are more attractive than a well-grown collection of healthy symmetrical pot plants; whether they are seen in a costly conservatory, or a plain unpretending structure, they are equally attractive and enjoyable. My purpose is not to enter upon the cultural details of any particular class, but rather to treat of the management of pot plants generally.

The first and most important point is to start with healthy plants of a sturdy, compact growth after their kind, and to strive to maintain them in a flourishing condition as long as may be desirable. The means to this end comprise clean flower-pots, suitable soil in a thoroughly sound and sweet condition, and a proper temperature in a suitable house. It may be well to take these simple conditions more in detail. No flower-pot ought ever to be used till it is washed clean; if this wholesome rule were attended to more strictly, unsightly pots encrusted with filth would not be so common, and the plants would not only look all the better, but be decidedly healthier. It is a good practice to have a couple of tubs of water standing near the potting-bench, one for soaking the pots in for a day or two after any plants are shaken out of them, and the other for

rinsing them after they are washed, so as to have them quite clean. It is highly important to have plenty of shed room, so that a portion of all the sorts of soil likely to be called for may be stored close at hand in the potting shed; a series of spaces with boarded partitions are best, and they present a very neat appearance. Thus there might be a space for silver sand, one for loam, one or two for peat, one for leaf mould, another for manure so decayed as to be a rich soil, another for charcoal, another for broken tiles, and so forth. In all these a full supply should always be kept. No practice can be worse than to go to the soil yard for soil just as it is wanted for the plants, for it is there exposed to all the vicissitudes of the weather; dried by the sun, and saturated by the rain, it can never be used with any degree of certainty.

Extremes of temperature are hurtful to all plants in a greater or less degree; when plants are subjected continuously to even a few degrees more heat than their nature requires, the effects are soon visible in the attenuated growth and delicate, or rather sickly, condition which they present, and which is even more hurtful than the stunted growth and discoloured foliage induced by the other extreme, yet from which a more favourable temperature will in most instances recall them. Take, for instance, a Pine Apple plant, which will, perhaps, bear more ill-treatment than any other; when subjected to an extremely low temperature its foliage becomes of a pale sickly hue, and many of its roots perish; but after such a trying ordeal a few weeks of fair treatment effect a marvellous change in its appearance, and from being a miserable, unsightly object, it becomes a flourishing plant, such is its wonderful vitality. But though this favourable change may be produced by judicious treatment, such faulty culture deserves no praise; the fruit of a Pine Apple, the flowers of any plant, so badly treated, invariably fail to develope that high degree of excellence usually visible in the crop of those plants whose vigour has sustained no check at any time.

In considering what kind of structure is the best for plant culture, the mind recalls many an old, almost flat-roofed house, with paint and putty perished, abundance of cracked glass, and immense heavy rafters, where plant-growing beset with difficulties has been practised, and yet a tolerable degree of excellence attained. The very best kind of plant house is a light airy span-roof, not too lofty, with suitable staging, and with a thorough command of plenty of heat and fresh air. With such advantages plant-growing is an easy and pleasurable affair, the abundance of light on all sides tending materially to promote an even and symmetrical growth in every part of a plant, so that the constant shifting and turning about become unnecessary. One of the most important principles in plant culture is cleanliness; given plants with clean foliage, clean pots, sweet soil, a pure atmosphere, tempered to suit the plant's nature, the woodwork, glass, and every part of the house clean, and success becomes almost a matter of course. Knowing the importance of all this, one cannot but wonder at the miserable style of plant-growing which is met with but too often. A host of plants crowded together in undersized pots, their long drawn-up shoots producing a few poor, puny flowers, are just a miserable set of caricatures, two-thirds of which would be better on the rubbish-heap, and the man who has brought together such a collection would be much more in his proper place with a fork turning that heap than inside a plant house. As Mr. Keane has told us, "it is better to grow a few plants well than many badly," for a few well-chosen plants brought by skilful treatment to a high state of excellence, must afford more real pleasure to all who see them, than the most extensive collection could ever do when spoilt by bad treatment and the absence of all those important conditions which I have endeavoured to enumerate.—Edward Luckhurst.

AMERICAN POTATOES.

It is quite pleasant to see the truth told at last by "D., *Deal*," about these wretched impostors. My experience entirely coincides with his. In 1869 I first planted the "Early" (!) Rose and Goodrich Potatoes. I was much struck with the vigorous habit of the former, it seemed so distinct and promising. In the month of July of that year I had some taken up for cooking, with some Ashleafs growing alongside. They were as large as these, but watery, nasty, and uneatable. In September I again tried them; the tubers were large and good-looking, but on being cooked with great care they were found to be harsh and dry, with a hard centre, and a flavour perfectly original, but so unpleasant—nasty according to our cook—that I gave them up for that year. The misnamed Early Goodrich came in with the Regents, but instead of being like that sort in flavour, the tubers were earthy, with a peculiar, *un*earthly, and most disagreeable flavour. The past season I again planted Early Rose in a deep loamy soil resting on sand, a soil in which Ashleafs are fit for the Queen. It was again tried in July, and found, as in 1869, quite valueless. In October some fine handsome tubers were steamed in one of Barlow's steamers, and again yesterday; they were dry and harsh—not floury like our English sorts, and *most* disagreeable.

I hear that the other American sorts are of the same disagreeable flavour as those I have mentioned. I saw last year a lengthened eulogium on the Early Rose Potato in one of our periodicals, and afterwards found it in the catalogue of a London seedsman. So the climate or the soil affects these Yankee products, for unless they were different in America, the Yankees are too sharp to give a dollar a-pound, as they did for the Early Rose.—Thos. Rivers.

DOYENNÉ D'ALENÇON *versus* EASTER BEURRÉ PEAR.

Remarkably like each other in appearance are these two Pears. The first-named is, indeed, in general considered as a mere synonym of the latter variety, and is given so in almost every fruit list. Place a few specimens of Doyenné d'Alençon before the best pomologist and he will at once say Easter Beurré. It is, however, quite distinct and much superior, and that is saying a great deal after the lavish praises that some writers have of late bestowed on the French Doyenné d'Hiver, our Easter Beurré. Easter Beurré is good if well ripened, which is frequently not the case. It only succeeds well in certain favoured situations and localities. It generally requires a wall, and is then frequently pastey and hard-cored. If there is one locality in this country better suited for Pears than another, it is assuredly the Royal Gardens of Frogmore, and it is just there that the striking difference between Easter Beurré and Doyenné d'Alençon is made manifest. Whilst visiting these noble gardens in autumn, Mr. Rose and Mr. Powell kindly directed my attention to the two Pears. Looking at them in the mass (several bushels), the distinction was plainly seen. In colour of skin the Doyenné d'Alençon is more yellow than the Easter Beurré, which is generally of a greenish tinge. In the shape, the difference is slight but distinctive. The eye of the Easter Beurré is set in a flat or somewhat hollowed depression, the end being rather broad. The Doyenné d'Alençon has the fruit drawing more to a point towards the eye, like a Williams's Bon Chrêtien, the eye set without any depression; when a number of fruits are examined this distinction is very plain. In flesh the Doyenné d'Alençon is yellow, the Easter Beurré white. The wood, the buds, the growth, and habit of the trees are also different, the former being more yellow, pointed, and pendulous than the latter. The most important distinction, however, is that the Doyenné d'Alençon is of finer quality than the Easter Beurré when grown under the same circumstances, as manifested at Frogmore. Grown as an open standard at Frogmore, the Doyenné d'Alençon produces splendid crops of fruit of the finest quality, which supply the dessert for the royal tables during the winter months, whilst Easter Beurré is, on the contrary, very often unpresentable excepting for its size. Here, then, is an important matter for our fruit cultivators; we find in Doyenné d'Alençon a late Pear of the highest quality, suited for open standard cultivation, and we shall have to thank Mr. Rose for almost a new introduction and a welcome one.—B.

IMPROVING THE GENERA VIOLA AND DIGITALIS.

The finest improvement of a British plant by the hand of the florist, I think, must be considered to be the Pansy or Heartsease. In suitable soils no other British plant gives such a variety of rich tints; it rivals in texture and gorgeous colouring the vegetable denizens of the sunny south, and hybridises freely with kindred species and varieties, as Viola lutea and purpurea, which may be said to be the ancestors of this lovely family. I can see no reason why other species of this extensive family may not be improved in size of flower, in vigour of growth, and in richness of colour as well as in fragrance. I am not aware of anyone having taken the Violas in hand in earnest with a view to improving them. The varieties of Viola

canina (sylvatica) and hirta are charming pot plants, and do not "fog off" so much under culture as Viola odorata and its varieties sometimes do. Once let us get a start with the best forms of Viola sylvatica and hirta, and depend upon it there will be produced endless variety. All we want is a good break from the normal condition of the plant, and by following up artificial fertilisation and judicious selection important results must be attained.

As an instance of what may be done by judicious selection, I may mention that some years ago I undertook to improve Digitalis purpurea, the stately Foxglove, through seeing a variety that accidentally grew in a garden where I was gardener. The variety that took my fancy was a white one very lightly ticked or mottled in the throat with purple. Contiguous to this plant grew a white-flowered one and the common purple; they seem to have fertilised each other freely, bees, too, being very fond of them. Among the progeny were several varieties, and in four years I had produced forty varieties of Digitalis purpurea, some of them most beautiful, and many far superior to the Digitalis gloxiniæflora now sold at the nurseries. In moving to another situation I unfortunately left them behind, and so lost them; one in particular had a large campanulate-shaped flower more than twice the size of the ordinary Foxglove, evenly lobed all round, with a white ground, the inside being spotted and blotched much in the way of an herbaceous Calceolaria, the blooms not pendent, but standing out at right angles from the stem. At that time I knew not the importance of these results, and I may say twenty years will elapse from that date before another such collection can be produced. I have mentioned this instance as one amongst many that must occur in the gardening world. All novelties should be carefully looked after, for many a floral gem has been lost through carelessness.—W. E., *The Gardens, Cromwell House.*

NOTES MADE DURING A TOUR IN IRELAND.

No. 5.

THE CHIEF SECRETARY'S, PHŒNIX PARK.

This is another of the Government establishments, and in some respects superior to the Vice-Regal Lodge; the grounds, if not quite so extensive, are equally beautiful, and the whole establishment is very secluded and complete within itself, although in the middle of a public park. There is in the grounds a curiously misshapen tree, the trunk resembling a man standing on the crown of his head with his feet in the air. There are also some fine examples of Arbutus and Sweet Bays—beautiful evergreens where the climate is mild enough for them, likewise a fine Cupressus funebris, very elegant and beautiful in its changing character, and in the kitchen garden are four very large pyramidal specimens of Cupressus sempervirens. This is a plant which in our race after new things is beginning to suffer neglect, and such is the fate of all. Nothing is fashionable but novelty. It is, however, as a plant-growing establishment that the Chief Secretary's has been so justly celebrated, and well the present gardener, Mr. Bowen, although a young man, upholds its reputation. Many of the plants here are such as would have done the producer credit at an exhibition at Chiswick in its palmiest days.

Beginning with the conservatory, this is a large, lofty, elegant structure adjoining the house; it is at times used also for theatrical assemblies, and well adapted it must be for that purpose. We do not find many occupants at the end of summer, except very large Acacias, Cordylines, Grevilleas, Palms, &c., all in good condition; when decked up, however, with the fine plants to be seen elsewhere, it would look charming. There is a group of extremely convenient half-span pits, where Mr. Bowen cultivates his plants with great success. The specimens of Alocasias, Crotons angustifolium and variegatum pictum, Marantas, Anthuriums, Medinilla, Stephanotis, &c., were very fine, showing high-class cultivation. In another lean-to house there were some good New Holland plants, such as Pimeleas, Genetyllis, Eriostemons, Rhynchospermum, and Correas. It is quite a treat to find these plants cared for now, the whole interest seeming to have centred, as regards plant-growing, amongst ornamental-foliaged plants.

On the north side of the kitchen gardens we enter a range, 250 feet in length, of rather lofty lean-to half-curvilinear houses. This is a fine range, and gives an air of great importance to the whole place. These houses are principally devoted to Vines, which, although old, seemed to do well, with plants underneath. There were some fine large specimen Palms, as Areca Baueri, Latania rubra, and Cycas revoluta. I noticed also an interesting variegated sport of the Lastrea Filix-max, pretty enough, but scarcely desirable. One division is fitted with a bed or pit in the centre, in which the fine-foliaged stove plants in pots are plunged and thriving well; then against the back wall, which is formed with a sort of arched recesses, there is another narrow bed or border, in which Musa Cavendishii was succeeding remarkably well. I do not recollect ever having seen Musas, not even at Sion, so thriving or giving such a great result from so small a space. The bunches of the fruit, and the fruits individually, were very large. Musas having such enormous leaves necessarily require a considerable space. In general they are planted in the middle of a house and occupy it. Here, however, Mr. Bowen, having them in these recesses against the back wall, forces them in little space, and fruits them with great success.

In the front of this long range of houses runs a parallel walk, the borders on each side of which are planted in ribbon fashion with Pelargoniums, Calceolarias, and other plants, along with dark-leaved Beet. The line of Beet, taken by itself, was superb, as, indeed, were many other vegetables just alongside. The pyramidal Pear trees near here looked well, were full of fine fruit, and evidently well cared for. Some Damson trees were enormously laden, and on the walls there was a great crop of Reine Claude de Bavay Plum, a most useful variety. I noticed also fine crops of that famed Irish Apple the Ecklinville Seedling and of King of the Pippins, and in the fruit room, a good one, were some fine examples of Beurré d'Amanlis and Louise Bonne of Jersey Pears. As regards out-buildings, sheds, and every convenience of that sort, few places can equal the Chief Secretary's, and in Mr. Bowen is found an able gardener.

WHITEFIELD LODGE, PHŒNIX PARK.

This is the residence of the Ranger, Mr. C. McDonald, truly a charming spot, situated to the north, and near the west side of this great park. The place is but a few acres in extent, yet it is rich in Conifers. It is the private policy of the Ranger or Park Superintendent. Here the late Mr. Wilkie, who for so many years held that office, gathered together and planted for trial specimens of all the most beautiful Conifers and other trees, and now Mr. McDonald, who has so worthily succeeded him, has the pleasure of observing them in all their beauty; and seeing them as they are to be seen here one cannot fail to admire them. It was Mr. Wilkie's fine and cultivated taste which led him to plant his private grounds with a collection of rare trees and shrubs, instead of the present popular gewgaws of ribbon borders and flower beds. The one is a never-ending source of pleasure and beauty, the others, although beautiful at times, a never-ending source of expense.

Whitefield Lodge is pretty and ornamental, not so large as it seems, but convenient. It looks well from the park in its nest of Coniferæ, the deep sombre green of which contrasts so forcibly with the pale deciduous leafage. Why are there not more Conifers planted in this park, seeing that they succeed so well, and present such a marked feature in the landscape? I have to speak here of no design in planting or laying out. They are simply dotted about here and there singly and in groups, on a smooth, well-kept grassy lawn. Some have been crowded, and so have injured one another; this Mr. McDonald is gradually remedying by cutting down some and removing others. Many of the specimens are superb, and exceedingly beautiful. I can only notice a few of the more prominent. First, then, Cupressus macrocarpa, of which there are two very large, spreading, handsome trees. These, whether by design or accident, are fully greater in breadth than in height. What a pity that this fine rapid-growing Conifer should be so frequently injured by frost! In most places north of the latitude of London, all the large trees of this were killed in 1866. Wellingtonias seem to do well here, one specimen measured upwards of 25 feet. Thujopsis dolabrata is here quite hardy; there is a fine example of the variegated form 5 feet high. Cedrus atlantica, the most handsome amongst the Cedars, is doing well; so, too, is Cedrus Deodara. Of Abies Pinsapo there is an extremely handsome tree about 20 feet high; Abies cephalonica is 30 feet; Abies orientalis, 20 feet, very handsome; Abies lasiocarpa, very handsome, 6 feet. I also noticed Abies Morinda, Abies nobilis, and Abies Douglasii, which did not seem so happy as it is to be seen in the north of Scotland. Of the Cupressus tribe, besides C. macrocarpa there is here one of the loveliest specimens of C. nutkaensis, or Thujopsis borealis, which it is possible to contemplate; always graceful as this plant is, the example here, some 15 feet in height, is surpassingly so. It is in character and habit of growth per-

fectly unique and distinct, being of a very graceful weeping form. It is extremely worthy of introduction as a distinct form. There are also a fine pyramidal example of Cupressus funebris, about 18 feet high, a fine old C. sempervirens, and C. torulosa. Forming a fine central object stands a splendid plant of Taxus Dovastoni, a fine weeping form, with a great flat head upwards of 20 feet in diameter. I noticed fine lines of Irish Yews, always very effective, Golden Yews, Chinese Junipers, Thuja gigantes, extremely useful and fast-growing, and many more Conifers seldom to be met with. Here also is a fine little example of Quercus glabra bearing acorns, a very beautiful evergreen shrub, also some large Weeping Ash trees. The whole place is replete with fine trees, and full of interest.

It was with no small degree of pleasure that I inspected the plant treasures here along with my friend Mr. McDonald, and his wife, and have to thank the latter especially for her warm hospitality. With Mr. McDonald himself the gardening public in this country and in Ireland are already pretty familiar, he having been gardener at Woodstock, Kilkenny, for many years, where he so altered and improved the character of the place as to earn the most warm and grateful thanks of his employers, and the public approbation of the whole country. It was his merits and talents as displayed at Woodstock, that led to his being selected for the high and honourable post he now holds as Chief Ranger of the Phœnix Park. A better selection could scarcely have been made. If Ireland had all its servants like him, there would be far less disaffection and more contentment amongst its people. But the day is coming, Erin-go-bragh !—B.

CEANOTHUS AZUREUS AS A CLIMBER.

I do not think amateur gardeners avail themselves, as they might do, at their villa and suburban residences, of the very many beautiful climbing plants for decorative purposes. Some years ago I was travelling through South Devon in the autumnal months, and was struck by the sight of a very charming climbing plant at least 10 feet high, which was growing against the side of a house near Torquay. It was literally covered with a mass of light blue flowers. I had never seen anything like it before, for it appeared to be an unknown plant in the midland counties in which I then resided. Upon my reaching home I sent a description of it to your valuable Journal, with an inquiry as to its name, and on learning that it was Ceanothus azureus I at once procured a strong healthy specimen, which I planted against a wall with a southern aspect, giving it a slight protection in the winter, and most amply it repaid my trouble, and soon covered a large space with its beautiful racemes of sky-blue flowers in August and September. Unfortunately, for want of better protection, in the very severe winter of 1860-61 it was cut down by the frost. I would strongly recommend any of your readers who reside in the warmer parts of England to give it a trial, and I am sure they will thank me for the suggestion. Against the side of a house or a wall with a southern aspect it will be found invaluable. It should be covered with matting in severe weather. Independently of its flowers, its beautiful deep green leaves are in themselves an ornament.

I never pass a cottage in the country with bare red walls but I long to cover them with some of our many beautiful and hardy climbers. How many a country house which now looks bleak and desolate, and often, consequently, remains tenantless, might be made cheerful and picturesque by the outlay of a few shillings in the purchase and planting some of the best hardy climbers, taking care, of course, that they are properly tended and nailed when once they begin to run up.—Hortator.

Death of Mr. Mann.—Our readers will much regret to learn that Mr. Mann, the esteemed Superintendent of Hyde Park, died on Saturday last. We believe his health had been failing for some months.

Botanic Gardens.—A recent number of *L'Illustration Horticole* contains an interesting paper on the Botanic Gardens of Kew, by M. André, prefaced by some details regarding similar establishments in Europe. From this it appears that the first was established at Padua in 1545, followed by that of Pisa; those of Leyden and Leipzig date respectively 1577 and 1579. The Montpellier garden was founded in 1593, that of Giessen in 1605, of Strasburg in 1620, of Altorf in 1625, and of Jena in 1629. The Jardin des Plantes was established in 1626, and the Upsal Garden in 1627; that of Madrid dates from 1763, and that of Coimbra from 1773. At the end of the eighteenth century, according to Gesner, more than 1600 kindred establishments existed in Europe. England comes late in the list, the Oxford Garden not having been founded until 1632, and long remaining the only one in the kingdom.—(*Nature.*)

HYACINTH PRIZES.

I am very pleased to see the letter of "D., *Deal*," in your Journal, in which he makes mention of the poor encouragement given to the exhibitors of Hyacinths this spring. I wrote a letter last autumn on the subject, but it seems to have been disregarded by the Council. I wish some one would make a stir in this matter, and let us have a really good spring show.

"D., *Deal*," mentions also that he thinks the prize for eighteen white Hyacinths is a mistake, and so do I, and every one else I have spoken to on the subject. I have a very good collection of Hyacinths now growing, but though I have eighteen white ones, I have only sixteen distinct, so I shall be shut out from that entry. Besides, as only 20*s.* are offered in the amateur class for six Hyacinths, I doubt very much whether I shall exhibit at all. This I much regret, as having a large collection, and having been successful for the last three years, I think I stand a very good chance. If the Royal Horticultural Society feel so disinclined to encourage the growth of these beautiful bulbs, could not we subscribe together and offer a prize ourselves? I would willingly do all in my power.—Amateur.

THE WINTER IN LINCOLNSHIRE, AND ITS EFFECTS ON VEGETATION.

The winter in central Lincolnshire has been the most severe and continuous we have had for some years. In point of extreme cold it has not reached so low by several degrees as the figures given in other counties further south. But a word as to thermometers. It is possible the great differences in temperature recorded at different places may be more differences of instruments than of actual weather or cold. The instruments vary in registering cold about as much as clocks and watches in registering time. Both require correcting by authority to render them accurate and reliable. The names of makers, however great their reputation may be, are not sufficient guarantee for the instrument's truthfulness. I have thermometers stamped with the names of the most celebrated makers, and on the faith of such names I felt myself safely pledged as to their accuracy, at least some of them, for I could not fail to notice their differences. However, on their being tested by corrected and authoritative readings at Kew, I found how far out I was in my reckonings. The instrument I had vainly taken as my standard was in every part of the scale 2° too low, and in one particular point as much as 5° too low. Out of ten instruments examined only one was exactly correct, and it is a little shabby-looking thing without any maker's name attached. All the others varied from the standard, and all varied also in different parts of the scale of each. So much for names and appearances, and the importance of adopting the best means of testing to insure exactitude and confidence in figures.

To resume. The winter proper commenced on December 21st. Although we had had some frosts previously, it came upon us suddenly, for the morning of the 24th brought with it 25° of frost. From the beginning of the frost to January 28th, thirty-eight nights, the thermometer has been, with the exception of only two nights, below freezing point, while for thirteen consecutive days the maximum did not reach the same figure. The greatest maximum reached since the frost set in was 48°, and we have only had one day anything spring-like—namely, January 17th. For six nights during the frost the thermometer registered over 20°, with several more approaching this figure. The lowest figure reached was 6° on the morning of January 1st, or 26° of frost. Thus we had, no doubt, an aggregate intensity and continuation of frost, calculated to inflict very serious injury on vegetation; and, unquestionably, the injury would have been serious had not the means happily brought with it the most effectual antidote—the snow. Nothing could have compensated for the complete protective covering it has afforded, nothing could have come more opportunely; its value is beyond calculation; it has been, in fact, the gardener's and farmer's friend, and has stuck to him in his difficulties as a good friend should. It has never been over 4½ inches deep, yet for fifteen days it never wasted a particle. Its good-keeping properties were due to the very dull weather which has charac-

terised the frost. For days together the sun was hardly seen; we have only had one really bright day since the year commenced, and only two half-bright ones, all the rest being decidedly dull. Another feature favourable to vegetation has been a striking absence of wind. Old millers say that they have not for fifty years experienced such a still calm winter. There has been no blowing of the snow in wreaths, but it has lain quietly, doing its protective work. It has also been a singularly dry frost. Since December 21st to the time of writing (January 28th) the rain gauge, and this includes the melting of the snow, has only received 0.59, or a little more than half an inch of rain. There was a slight break on the 8th and 9th of January, when the first snow melted and the green pastures told of its protective care. Two days afterwards we had 20° of frost, but our friend the snow was again to the rescue with a covering of 2½ inches. This melted on the 14th, and since then, although we have had frost every night, it has not been severe.

Taking a look round the gardens we must, with all the winter's drawbacks, and considering its length and inteneity, regard it as a fortunate one. Plantations of Cabbages, Lettuces, and Cauliflowers, which must, but for the snow, have been nearly all killed, are almost as green and fresh as ever; while Celery, Parsley, autumn-sown annuals, &c., seem little the worse of the ordeal they have passed through. It is different with things above the snow line. Broccoli which was left standing is nearly all killed, while that which was laid down is nearly all saved. Brussels Sprouts are partially injured, and so are all the Kales, except Cottagers' Kale. One thing has surprised me, and that is the hardiness of Asparagus Kale—Couve Tronchuda of some perhaps, yet a hardy type of it, as it has, with the exception of Cottagers' Kale above noticed, suffered less than any of the Cabbage tribe, thus possessing two important qualities—hardiness and excellence.

As to shrubs, it is almost premature to speak definitely, but little or no injury is at present noticeable. Some Roses are certainly injured, but I do not apprehend the lose is serious. In the field the root crops are rather severely cut up, not being well covered with snow, but the breadths of Wheat have as yet received no injury whatever. Fortune has thus come out of misfortune, and taking a broad view of what has been and what might have been, I am constrained to sum up the frost as a fortunate one. It has had at least this advantage of bringing out the sympathies of the rich towards the poor, and making the hard times easier. One good result we are reckoning on from the protracted cold, and that is the retarding of the fruit blossoms and tiding them over the spring frosts. The trees look hopeful, and a good fruit year is anticipated. But is the winter over?

P.S.—The weather changed on February 2nd. The thaw is steady, appears general, and is accompanied with rain.—J. Wright, *Gardener to Hon. A. L. Melville.*

SLOW-COMBUSTION STOVE.

Many inquirers have applied for information relative to the stove described at page 69, and, as might be supposed, the same queries are put, with some variations, by all. Space will be economised by covering the sum of the questions in one reply.

The chimney ought to descend. It must not rise, for the carbonic acid produced by burning charcoal is heavier than the air when cold, and so will not ascend in a chimney when it has lost its heat. In the article in the number of January 26th it is explained why the chimney should have a slight descent. The end of it farthest from the stove is best placed about 1 foot or 15 inches lower than the throttle. Charcoal is never so well made but that it contains hydrogenous compounds which form water during combustion, and this drips out of the descending chimney when the combustion is very slow. It is another reason for adopting this disposition of the flue. Coke will not answer. It contains a large quantity (about 12 per cent.) of earthy matter, and will not, in consequence, commence to burn until a high temperature is reached. It is difficult to light, and is not at all the fuel to use when slow combustion with a comparatively low temperature is required. The cast-iron plug used in Joyce's stove would answer perfectly in lieu of the gas pipe. The chimney need not be of zinc. Zinc does not oxidise, and is very readily made into pipes, for this reason I chose it. The fire is best lighted by placing some charcoal in an old saucepan, well perforated in the bottom, upon the fire. When the charcoal is burning up it can be safely carried to the stove upon a shovel or slate, &c., to prevent dropping, and poured into the stove, which can be filled up as far as required immediately. My stove was made by Mr. Groom, of College Street, Camden Town, for 12*s.*

Of the price of fuel I can only give my own experience. Mine was bought in Litchfield Street, Covent Garden. Six sacks, each containing about 4200 cubic inches, were sent eight miles to my house for 15*s.* At the same time, however, a similar quantity was delivered to a neighbouring friend. Supposing this to be a fair price, the cost of heating can be arrived at thus:—Not more than would fill the stove to the depth of 1 foot would be required in a severe frost during one night. The diameter of the stove being 6 inches, the area of the cross section would be = 6 inches × 6 inches × .7854. This multiplied by 12, depth in inches, gives rather less than 340 inches, not quite the twelfth of a sack—cost about 2*s.* 4*d.* I have had fire to keep out damp, frost, &c., and sometimes continued it when not needed, and my consumption this winter has been five sacks nearly; about 12*s.*

One correspondent asks why his gas pipe will not answer in cold weather. All gases hold a certain quantity of water in solution; more when warm, less when cold. The gas pipe exposed chills the gas, and the water held by it when it left the metre is condensed upon the inside of the pipe in the form of dew. This collecting soon fills the pipe in its lowest bend, then freezes, and the supply is cut off. The only cure is to have a pipe with a continuous fall to the greenhouse, and fix there a fall pipe to receive the water, which can be drawn off at intervals.—F. Cheshire, A.C.P.

WEATHER PREDICTIONS.

I fear I cannot endorse the opinion put forth by your correspondent, "Amateur, *Cirencester*," about the weather-prediction theory referred to at page 85 being always correct. The basis of this theory I take to be that when the first seven months of the year are dry, so that the rainfall for that period is less than 10 inches, a severe winter is likely to follow. Further, it was predicted by the gentleman who promulgated the theory that the present winter would probably be a severe one, the prediction appearing early enough in the autumn to insure its author every credit for not waiting for the event and then recording the prophecy. Applying the theory to former years here, I may say that there have been only two seasons during the last sixteen years that the rainfall of the first seven months of the year—*i.e.*, from January to July, both inclusive, has been below 10 inches, but there has been one in which exactly that quantity fell, and one in which there were 10.23 inches, and one case is added of an opposite character. The rainfall of the various years given beneath is for the first seven months alluded to.

1857	10.23 inches.	1868	10.56 inches.
1858	9 81 „	1860	19.00 „
1864	10.00 „	1866	19.66 „
1870	8.28 „		

Now, taking the winter of 1857-58, I find the following notice of it made: Autumn very fine, winter dry, spring dull.

Taking the ensuing winter 1858-59, the remarks made are: Autumn dry and fine, winter mild and dry, spring medium.

For 1864 I find recorded: Autumn mild but wet, winter wet and cold, spring fine.

In 1868 a mild, wet autumn was followed by a winter of like character, and an early spring.

1870 is too fresh in memory to require comment, but one or two instances where a hard winter has followed a season the reverse of that predicted may be given.

1860-61: Autumn wet but open till the middle of December, when some very severe weather set in, followed by a favourable spring.

1866-67: Autumn very mild, winter exceedingly severe, spring late.

The above being all at variance with the theory, show the uncertainty of weather predictions.—J. Robson.

The Effects of the Winter in Norfolk.—A thermometer on a north wall registered on the morning of December 24th, 4° Fahrenheit, and at 12 o'clock at night, 3°; on the morning of the 25th it was at 5°. There was a heavy fall of snow on both days. Several Roses are killed, Laurustinus is killed to the ground, common Laurels very much injured, Deodars and Pinus Edgariana very much browned. I am afraid some of the Pinuses are very much injured; they scarcely

show it yet. A plant of Maréchal Niel Rose against the south front of the Hall, I am afraid is killed; it was slightly protected. —E. Sendall, *Barningham Park, Hanworth, Norfolk.*

THE CHISWICK GARDEN OF THE ROYAL HORTICULTURAL SOCIETY.

On Tuesday next the Royal Horticultural Society holds its Annual General Meeting for the purpose of electing a new Council and office-bearers for the ensuing year, when the Fellows also will be made acquainted with the condition of the Society, and will have an opportunity of discussing matters with respect to its future management and arrangements. It would be well for Fellows, therefore, who are interested in the Society's welfare to attend the meeting and support the Council in their good work, or, if necessary, to unsparingly condemn it. From all outward appearances, as far as I have been able to judge, I have good reason to anticipate a very favourable report and a more pleasant balance-sheet than usual. I have faith in the present Council and office-bearers that they will not needlessly plunge the Society into debt; in fact their special mission appears to be to save the Society from the utter collapse which seemed to be threatening it last year. I hope and believe that the worst times of the Society are now past, and that the present season, 1871, will be the commencement of a brighter era for the Royal Horticultural Society than it has yet seen.

There is something, however, besides squaring accounts and making two ends meet. The Society was incorporated for the promotion of horticulture. This is the only legitimate aim and object of the Society. For a time this end was faithfully pursued, and immense have been the benefits derived by horticulture from the labours of the Horticultural Society in their experimental garden at Chiswick. There is no need to enlarge on this point, as Chiswick and the good it has done to horticulture are of world-wide renown. But can the same be said of the doings of the present Society? What portion of the vast income of this great Society is being devoted to the pure pursuit of horticulture? I scarcely dare to ask. Yet I ask this in the name of horticulture. As a horticulturist I do not forget that at the last Annual Meeting of the Society one of the most unwise proposals that ever emanated from a managing body was brought forward—that relating to the giving-up of our Chiswick Garden. Urgently as the sacrifice was advocated as necessary for the very existence of the Society, happily Chiswick yet remains to us—Chiswick yet remains for horticulture as *the* garden of the Royal Horticultural Society. It is greatly altered, it is true—reduced in size, shorn of its fine arboretum and most of its ornamental portions; but as now being remodelled it will prove far more useful as a great experimental garden than it has been for many years, if sufficient funds only be allowed for that purpose.

For the Society to give up Chiswick would be to give up all that it possesses of the most useful. Chiswick has to contribute even to the glorification of South Kensington. Without Chiswick or some other equally suitable garden—and where could that be found?—South Kensington could not exist. All the plants and flowers which are used for the decoration of South Kensington are reared and nurtured at, and forwarded from, the Chiswick Garden. Has it ever occurred to the Council to inquire how much such a supply of plants and flowers would cost, supposing they had to be procured elsewhere? I never see any mention of this as put down to the credit of Chiswick, which in all fairness it should be. Quoting now from official statements, I find that in the years 1868 and 1869 there were each year sent up to Kensington over 50,000 plants, which at a very low estimate would represent a value of £1200. That is what South Kensington would have to disburse supposing they had to be purchased from any nurseryman, and it is extremely doubtful if anyone could be found to supply the same quality of plants for anything like that sum. Chiswick also provides, and supplies to the Fellows, every year about 10,000 or 12,000 plants, besides many thousand cuttings of fruit trees, &c., from its magnificent collections, as well as about 100,000 packets of seeds, which may be, as some of the grumblers observe, of little account, yet by a great many they are appreciated, and they represent a considerable amount of value. These plants, cuttings, seeds, &c., which are supplied to the Fellows represent a value of at least £500. In addition to this Chiswick hands over in hard cash, as the receipts for the sale of fruit, &c., an annual average of between £500 and £600, which gives us, therefore, a yearly return of something like £2250 from the Chiswick Garden (and that, too, independently of the value or cost of any experiments that may be conducted, or reports and general information supplied to the Fellows and to horticulture), equal to the total expenditure on the entire garden. Chiswick, then, as I have shown, clearly pays its way without the subscription money of a single Fellow; and yet in the face of all this it was proposed to give Chiswick up, as there were not sufficient funds to maintain it!

Chiswick remains—at least about 13 acres of it, which are now being laid out in most admirable style by Mr. Barron. When the works now in progress are completed, and the contemplated arrangements carried out, Chiswick will be more complete and better fitted as a great experimental horticultural garden than it has been for some time. One of the most useful works of the Horticultural Society was the publication of its "Fruit Catalogue," and perhaps the best collection of fruits yet exists in the Chiswick garden. It is gratifying to learn that this is to be maintained, and that the attention of the Society is to be turned strongly in this direction in the classification, description, and elimination of our fruits, in which there is at present much confusion. The maintenance of a collection of our fruit trees true to name appears to me to be one of the Society's most important duties. It is one of the benefits which are keenly appreciated by nurserymen, who can depend upon getting their stock true. All fruits should be grown in the garden, proved, described, retained if worthy, if not, discarded at once. I cannot enter here, however, into what is the duty of the Society, or what might be done at Chiswick. The Society has now in its Fruit, Floral, and Scientific Committees such able bodies of men, that it only wants the wherewith and it could be done. A great deal might be done, yet it would be unwise to attempt too much. What is done at all in the way of horticultural experiment ought to be done well, and no restriction as to cost and care ought to interfere, otherwise the trial may be abortive. Sufficient means and discretion ought to be allowed the manager to conduct in the best possible manner whatever is attempted, so that the desired end may be obtained. Two-thirds of Chiswick having now been given up, surely the one-third can be maintained respectably. I ask the Council for this in the name of horticulture; I ask them for this as trustees of all great horticultural interests.—F.R.H.S.

VERBENA CUTTINGS.

I take off cuttings or side shoots in the second week of July, and, after pinching out the bud or flower, insert them into pans with sand, and apply warm water to half an inch above the sand. I place them in a closed frame with no shading, and take every precaution to apply three times a-day a little warm water, if the sun is unobscured and bright, to prevent their drooping. In nine days the pans will be filled with roots. When this is the case I immediately proceed to pot them off, putting five in a 3-inch pot, and replace them in the same frame as before, shading and keeping them close for three days. I then increase the amount of air and decrease the shading, not forgetting with my thumb and finger to stop or pinch to every third joint. I well harden them off before winter. In this way I never fail to secure a good supply of Verbenas. I have at present on the average thirty-five cuttings from each five cuttings of last autumn in the 3-inch pots.—J. F.

[There are many ways of attaining the same object, but we do not see the particular propriety of using warm water to cuttings in a cold pit in July; we would rather wait a few days longer for the rooting. As to the potting afterwards there can be no objection, quite the reverse; but many must have these plants in abundance, and yet not find room for the potting. The writer, to whose statement you allude, has had no trouble with Verbenas, either with or without potting, and therefore your plan, however successful, does not throw any light on the cause of the disease. We are reminded of the time when the black-spot leprosy appeared in many places among Calceolarias. There were numerous statements as to how these plants were managed successfully, and many prided themselves on their own skill and treatment until the disease came upon them, and they were forced to part altogether with some favourite varieties. Just so in the case of the Cucumber disease—some of the best Cucumber-growers made light of it; while others equally distinguished gave us the epitome of their practice, with the side hint that if such practice were closely followed there would be nothing seen of the disease. But as if to teach us how little we know, we may state that some of these

very men for several years have not been able to keep their Cucumber plants from the disease, though the plants seem to be healthy and vigorous enough at first. Some of these men have been distinguished growers of Cucumbers for thirty or more years, and now they are obliged to confess themselves completely beaten. Another man adopting the same practice, and only a short distance off, has never yet seen a symptom of the disease. In the case of the Verbenas to which we referred, something might be owing to the dry summer and the inability to water; but the cuttings struck well enough, and it was after they seemed well established, though the plants were small, that they began to give way, first at the point, and then downwards, until there was no life left. Though there might be something tending to disease in the cuttings, we do not think that, or anything in the management, wholly accounts for the result. It is not pleasant to acknowledge ignorance, but it is often the best and surest step towards gaining valuable knowledge.—R. F.]

DOUBLE-FLOWERED PELARGONIUMS AS BEDDERS.

I HAVE great pleasure in replying to Mr. McCrow's inquiries (see page 63), but fear my answer will not be so agreeable to him as he would like, my experience of double-flowered Pelargoniums on the whole not being satisfactory; nevertheless, it may be quite as important to make it known as if it had been more successful.

In 1869 I planted two circular beds, each 10 feet in diameter, with the only two kinds I had then in sufficient quantity—viz., Gloire de Nancy and Madame Lemoine, and judging from what I had seen of them the year before, I calculated they would turn out rank growers; but as the bed had that spring been heavily cropped with Forget-me-not, I thought the partially exhausted state in which it was would check the growth of the Geraniums—indeed, it was a mass of roots and quite dry when turned up—and as they had to be planted out of cutting-pots or boxes without any ball, I feared they would die if placed unassisted in soil in such a condition, I therefore, at planting, put a little good soil around the roots of each, and after giving some water left them to their fate. They all grew on quite strongly enough, but the flowers were never so numerous as to make the beds conspicuous, as Geranium beds ought to be, and the season being moister than last year, very few perfect heads were produced. The wet settling in the centre of the truss, decay set in long before it ought to have done, and a bad appearance was the result. Nevertheless, as I had several other kinds last year, and as a good bloom of a double Geranium is of much service for bouquet-making and similar purposes, I planted out some more, and the season being dry they succeeded much better, producing more flowers, and these up to September were less liable to decay, but after some showery days in the early part of that month, coupled with the longer dewy nights that followed, perfect blooms soon disappeared, otherwise they were much better last year (1870), than the year before. Still the liability of the central portions of each flower to decay is a defect in double flowers not easily surmounted. Varieties not so close-headed might be better, and I still hope they will prove useful. Perhaps the best position for double Geraniums is a vase; their tendency to gross growth is there effectually checked, and their elevated position enables them to shake off sooner than if they were on the ground the moisture which causes the decay of the flowers; some we had in that position last year were much admired.

Mr. McCrow is quite right in saying plunging Geraniums in their pots in the beds is not a new plan, for I have seen it practised quite thirty years ago, only the purpose then was different from that which Mr. McCrow mentions. At that time they were plunged in their pots in June, so as to be readily taken up again in the same way in October, but I have seen single ones often enough planted out in their pots, but their roots have a perverse tendency to find their way through the bottom of the pot, thus defeating the object, for they grow rampantly enough then. When a number of plants in pots are plunged together, the roots of some getting through, and those of others not, there results an irregularity of growth more unsatisfactory than when all the plants are strong, so that on the whole planting in poor soil is preferable.

In reference to the decay of the central pips or portions of Geranium flowers, I may further remark that the Nosegay class of single Geraniums are also more liable to this failing than those with broad petals. Last summer this was conspicuous here, for while such kinds as Cybister, Waltham Seedling, Stella, and Duchess of Sutherland might at one time be called the pride of the garden; Punch, Crystal Palace Scarlet, and some others far outshone them at the end of the season. —J. ROBSON.

AMATEURS BEWARE.

I HAVE before me the "Garden Oracle" for 1871, which is to me a new publication. It contains a great many useful tables, if they can be relied on. In looking over these tables I was particularly attracted by one headed, "Seed required for a garden of one acre." This list is begun with Peas 36 quarts! What gardener in his right mind would ever think of ordering 36 quarts of Peas for a garden of one acre? or if he did, where would he find room to sow them if he had anything else in his garden at all? And what amateur could afford, or would like to afford, such an expensive seed bill for one acre of garden? I consider that nearly all the quantities named are greatly in excess, but the most flagrant error in the list is "Sweet and Pot herbs 6 lbs." Does the editor of the "Garden Oracle" mean that the whole acre is to be sown with sweet and pot herbs? if so, I hope whoever tries it will be well-flavoured. To satisfy my curiosity I summed up the amount such an order would come to from the prices of Messrs. Veitch & Sons. I did not select any particular sorts, but took an average of prices, where there was enough variation to allow me to do so. Peas I priced at 1*s.* 6*d.* per quart, which gives £2 14*s.* for that one article; sweet and pot herbs 3*d.* per packet, or 1*s.* per oz., then 6 lbs. at 1*s.* per oz. would be £4 16*s.* Herbs for ever! The sum total of the list I make out to be £14 16*s.*

How long will writers of books and calendars be allowed to issue such lists as these to deceive the inexperienced amateur whom they profess to aid and assist? Practical gardeners know better, and are not so apt to be misled, but no doubt it is very difficult for amateurs, especially those who are for the first time about to try their hand at gardening, to make a suitable selection, either in quality or quantity. They will sit for a whole evening in the midst of catalogues and seed lists, studying the name of this and the price of that, till their brains get in a whirl, and they fly back as a last resource on some list of "Seed required for one acre of garden," only to find out the error they have committed when the day of reckoning arrives. I experienced the same difficulty in selecting seeds when I first commenced gardening on my own account, and had I then sent to my employer a bill of £29 12*s.* for seeds for a kitchen garden of two acres, I should not be sitting here to-night to tell the tale.—G. S.

DINNER-TABLE DECORATION.—No. 1.

No small degree of interest was manifested some years ago when prizes were offered at the Royal Horticultural Society's Shows for the best arrangement of flowers for the dinner-table, and the interest evinced was increased when other societies took the matter up, and manufacturers furnished designs for stands suitable for the flowers or fruits employed. As a consequence, great importance became attached to that part of the show where the dinner-table stands were exhibited, and comments in accordance with the ideas of the inspectors were varied, but in general the class of stands called March's stands received the most attention, and became for a time the standard by which others were judged. I ought, perhaps, to have observed, that prior to this prizes had been offered for collections of plants either in flower or not, that conformed to a certain size and could be made available for table decoration; but those exhibited certainly fell short of meeting the requirements of the time, hence the necessity for flower stands. At succeeding exhibitions the competition in dinner-table decorations was continued, and with increasing interest, ladies of the highest rank being amongst the competitors, and by degrees greater diversity was introduced into the stands prepared for the purpose, including some scarcely elevated from the table, the latter class taking many fanciful forms and many different names, while in conjunction with them might occasionally be noticed a stand of greater height.

As the viands are, as a rule, no longer placed in bulk on the tables of the great, the space at command for ornament has been much increased. Happily for the gardener or whoever has to carry out the decoration, the fashion still remains of covering the table with a white cloth, and nothing can possibly show-off to greater advantage the masses of foliage, or it may be high-coloured flowers, and at shows where designs for dinner-table decorations are exhibited, the white-cloth base is invariably present. Were it not also always so on the dinner-table, there would often be a difficulty in supplying in mid-winter a sufficient quantity of flowers that would look well upon a background of another colour, for the white affords scope for the display of almost everything that grows, but more especially of foliage of compound growth, to which it imparts an embroidered appearance. I must not, however, dwell longer on this point, but will proceed with some of the modes of furnishing flowers and foliage so as to produce the best effect as a whole.

Many years ago, when dinner-table decorations first attracted public attention, I ventured to suggest that every description of ornament that intervened between the countenance of one person and another at table was bad; in other words that nothing should be elevated more than 14 inches from the table-cloth, nor, if suspended, should it hang lower than 24 inches from the table, thus leaving a clear space of 10 inches for one person to see another. I find there are many converts to my views; even some of the stands assume to secure this, especially

those of the March pattern, which have a small cup for flowers on the top of a single glass rod proceeding from a pan of flowers on the table, but it usually happens that the pendant flowers so essential to the appearance of the upper basin occupy the line of view I wish to keep clear. However, others must determine whether or not the beauties of such things counterbalance their disadvantages; but it is certain that many ornamental stands do interfere with this line in a greater degree than those alluded to, and some in themselves are highly ornamental. I may here observe, that the most costly are by no means the most effective, silver and other metals seldom looking so well as plain glass when brought in conjunction with flowers and foliage, and carved work and ornament on metals are worse than lost when partially screened by the foliage, the plain parts alone looking well. I know much disappointment has resulted from this, and at exhibitions the costly articles of plate, though creditably set out with flowers, &c., have often been beaten by more common-looking stands of plain white glass. Perhaps, however, when a silver stand takes the form of an epergne, its richness and costliness may attract attention, but the floral display must not be overdone, and the fault of a great many such contrivances is, that the bowl for flowers is much too large, necessitating an unwieldy and unbecoming mass; but of late years there has been great diversity of designs, some being of glass with small baskets of the same material suspended from them in which to place flowers, and some are formed of china with sculptured figures, but I confess having a dislike to them, and in general I would give the preference to glass.

Although more might be said about the class of ornaments which are elevated a foot or upwards from the table, I will pass on to those of a dwarfer form, not but that there are many pretty tall designs, but as those which are of less height afford still greater diversity, and, what is of more importance, opportunities for an infinite diversity of design at a very small cost, and with an effect as pleasing as the other, I have the greater confidence in recommending it, and having had as much practical experience of the working of the affair as most people, I speak with the more assurance.

In the first place I consider that for a good display of floral beauty, or in its place that of foliage, on the table, the table itself ought to be wide—certainly not less than 5 feet, and if 1 foot more so much the better. The tables I have had most to deal with are between the two measurements given. Assuming the table to be lighted by candlesticks placed upon it, these are generally placed in a line down the centre, and say about 3 feet apart, and intermediate between these a stand of flowers, or it may be a plant, is often placed, while, possibly, some piece of plate or other ornament occupies the centre of the table, and the dessert dishes are placed about midway between the outer edge and the middle. The understanding being that the dinner is to be served *à la Russe*, a considerable portion of the tablecloth is available for ornamentation, and various are the modes in which this may be done. When a number of visitors are likely to remain for a week or more at a time it is advisable to change the design every day, and this may be done by adopting some of the means that will be described below, none of them being expensive; at all events great diversity may be secured at little more than the cost of preparing the materials at the moment they are wanted, and these at most country places are at command. I will therefore assume that the dessert dishes occupy positions about 18 inches apart along both sides of the table. We frequently make use of a set of troughs of zinc about 2 inches wide and about ¾ inch deep, and made in a half-circular form, so that when two are placed together they form a perfect circle or ring. These troughs usually have the sides painted green (but I am not sure but some other colour would do as well), and being filled with sand are dressed with such flowers as are at command. Early in the summer Roses are often used when plentiful, later in the season the flower beds yield Geraniums, &c., and in autumn Chrysanthemums. In all these instances it is advisable, before putting in the flowers, to dress the edges—that is, to fix some kind of foliage in the sand so as to hide the edges of the trough in a neat and becoming manner, yet without proceeding too far. All descriptions of foliage are not adapted for this purpose; the leaves of Roses answer very well, and those of Geraniums are not amiss. In winter we are often obliged to pick out suitable leaves of Ivy, as a leaf that sticks out at right angles does not look well; only such as lap over are suitable. Ferns, however pretty elsewhere, cannot well be worked in here. Sticking in the flowers is an easier matter, and I would certainly not advise more than one kind to be used, or at most two, while only one kind of foliage is wanted. To those inexperienced in such matters I may say that flowers of a blue, purple, or violet colour do not look well by candlelight, while scarlet, crimson, yellow, and white are very effective, and most star-shaped flowers, as Cinerarias, look well. A good proportion of green is also advantageous, especially when white or yellow flowers prevail, and these colours, when having a green border between them and the tablecloth, look better than most others. As flowers are very scarce in winter, it is often advisable to make the most of those which are to be had, and, having two or three sets of troughs, we plant one entirely with Selaginella denticulata some time before it is wanted, placing it on a hotbed or other medium affording bottom heat, in order that the Lycopod may make sufficient growth before it is wanted, and we then bring out that set in place of the made-up one, and its appearance on the white tablecloth is, perhaps, more pleasing than the floral arrangement. The overhanging sprigs are generally sufficiently numerous to hide the edge of the trough, and they show their beautiful configuration to the best possible advantage against the white background. Sometimes it has been thought advisable to stick in a row of light-coloured Pompon Chrysanthemum flowers along the centre, like a row of beads or buttons, but I am not sure that this is any improvement; it certainly destroys the belief that a living plant only is before you; and whether the floral display compensates for this or not I leave others to determine. At all events if flowers are to be used let them be only of one kind and one colour.

It will be seen that the troughs, being all semicircular (although of two sizes so as to meet any irregularity that may occur), are capable of being placed in a great number of forms, but one of the most pleasing is a series of scollops all around the tables, enclosing a dessert dish or something of that kind; perhaps a wider scollop may be wanted at each end, or it may sometimes happen that the troughs do not exactly touch each other in all places, but a little extra dressing will make up the difference, and to meet this difficulty we have a number of straight short troughs which may be worked in, but we seldom require them, either the one size of circle or the other sufficing for our purpose. When it is advisable to work the semicircles into a sort of serpentine form these short lengths come in handy, likewise when a square or a straight line is desirable; they are also useful to unite the curves, but in general the latter do their work well, and are capable of being worked into circles surrounding each object in the centre, or it may be at the sides; in fact, they can be arranged in several ways which will suggest themselves to the decorator.

In addition to the curved troughs alluded to, we have also sets of straight ones to form a straight bordering around the table; these are of the same description as the others, and are planted or dressed in the same way. They are from 1 to 2 feet long, with curved corner pieces. Generally they are placed all round at about 14 inches from the outer edge of the table, so as to leave room for the plates and other requirements of the company. Some admire them more than they do the curved ones, and they come in well as a change. There are, however, other modes of dressing besides those in which the trays are used, and sometimes very simple applications of very common things are better than more costly contrivances. Those I shall describe are mostly of this description, and I would invite opinions on them; at the same time the advocates of lofty stands for flowers, &c., will see that the contrivances above described do not in any way prevent such being used, neither do those which are to follow, excepting in one case where the novelty of the arrangement seems to forbid anything high intervening.

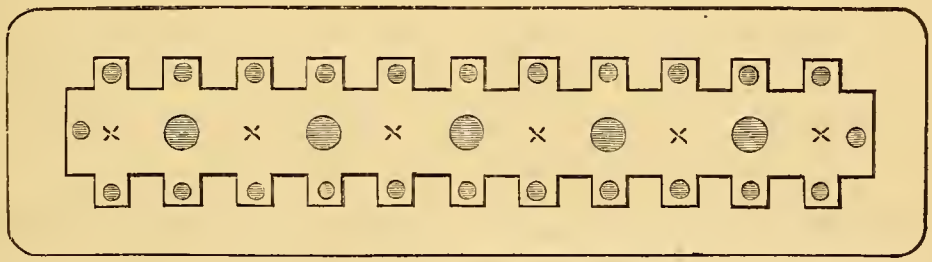
Where a long round of dinner parties has to be provided for, and that perhaps in winter, especially where bouquet-stands have to be daily made up for the drawing-room, and now and then tall stands for the dinner-table, the drain upon the flowers for these purposes leaves but few for what may be called flat-table decoration; consequently foliage alone, or relieved with berries, has frequently to be adopted. Here there is scope for great diversity of design, although the materials for the purpose ought to consist of small foliage only, as the extreme width of the figuring ought not to exceed 2 inches, and that without cutting-in any of the leaves, as is often done in preparing letters and other things of the kind for church decoration. Box is one of our greatest favourites, but we also use Yew, one or two kinds of Cypress, a small-leaved Phillyrea, and one or two others. Box, owing to the number of its bright

shining leaves, looks best at night; suitable sprigs are tied upon wire bent to the design fixed upon, and are quickly laid upon the table, care being taken to turn upwards as many of the leaves as can be done, and if the figure is of a pleasing character its effect is good. Of course, a knowledge of the position of the important objects on the table is necessary in order to work out the design to scale, which is not a difficult matter, as provision can easily be made for having some of the parts longer or shorter as required. With this object in view, it is advisable that the design should be in a great number of pieces, none of them more than 3 feet long following the curves, and few that length. We use galvanised wire that has become dulled by exposure, as most nearly approaching the colour of the stems of the evergreens, and no stouter than will merely bear handling and carrying about; twigs of evergreens are neatly tied to it with some dark coloured string, beginning at one end and making the top of one sprig overlap the butt end of the other, in the ordinary way of garland-making. Figures so made will last quite fresh a fortnight or more if kept in a cool moist place. We lay ours out of doors where they will not be dirtied, but will be exposed to all the rain and snow that falls.

Figuring of this kind, as will be seen, can be made to intersect the table in any fanciful form, like so much embroidery, and the deep green foliage stands out well upon the clean white tablecloth. Curves of, say, about one-third of a circle, may cross each other at their ends and form a continuous chain-work of elliptical links and lozenge-shaped ones alternately, which may each enclose something required on the table. This chain includes the ends as well as the sides, leaving the space of 14 inches next the outer edge quite clear for the plates, &c., the same as in the trough system; in fact, in all cases this space must be left untouched. The curves may also be formed into other designs. A little alteration from the above will allow of their being formed into what gardeners call the Florentine chain, which is a continuation of portions of the letter S overlapping each other; a still further alteration, but at the same time requiring a separate set of wire forms will make scrollwork, which, partly encircling the base of each dessert dish, looks very well, the whole being connected by the serpentine line; or the scrolls may be made to exhibit themselves on the open spaces of the tablecloth, but there is seldom room for this, and, as I have before observed, I am averse to any mutilation of leaves to form very fine work, which I have never found answer. There are many other modes in which this kind of evergreen embroidery in a curved or serpentine form can be wrought into agreeable forms, and I will now pass on to another class, which is straight work; here, again, there is great diversity.

Many years ago the writers on landscape gardening found great fault with straight lines, and avenues so planted were to them an abomination, consequently there are but few such at the present day of thirty or forty years' growth, but more recently their claims to importance have been recognised, fresh ones are being planted, and straight lines after all have been thought to have their merits; for the purpose at present under consideration I am not certain but they will be thought more ornamental and effective than curved lines, while their introduction alternately with these produces an agreeable change. In our case we use the same materials as with the curves, or rather use one of them; if the curves be of Cypress we make the next piece of Box, or of something else, on a wire frame, and mostly in short straight lengths. Sometimes it is advisable to have pieces like the letter L; and for a sort of Grecian pattern that will be described below, pieces bent so as to form three sides of a square are found very useful. One mode of using these straight pieces is to form a border all round the table, and to let other pieces cross each other in the centre diagonally, dividing it into a number of lozenges and triangles, a short piece uniting their points with the outer bordering in the manner of lead-casemented windows. Of course each square and triangle is expected to contain something wanted on the table.

There are also modes in which the straight lines can be called into requisition, and which will easily occur to the decorator; but that which has been generally most admired here



Dinner table, with twenty-four dishes of dessert, six candles, as represented by the crosses, and five stands for flowers. If there be a central object, as a piece of plate, only four stands will be wanted, and these, if necessary, may be in pairs, the two end ones being alike.

is a simple form of what I believe in architecture is called the Grecian fret, and which is represented in the accompanying engraving. A number of wire forms are bent into the shape of three sides of a square; the two angles, being right angles, are dressed in the manner described, and assuming the sides to be each from a foot to 15 inches in length, as may be required, one such piece is laid round the base of each dessert dish, with its points towards the central line of the table, and just as many single straight pieces of the same length as each side of the others will be wanted to unite the three-sided pieces together, the whole forming a design round the table, with every turning at right angles. Of course care must be taken to have the lines correct both longitudinally and crossways, and when neatly done, the agreeable simplicity of the design has generally found a greater number of admirers than more elaborate devices. Perhaps it may be incorrect to call this the Grecian pattern, as it contains so few turnings, and the battlements of some old towers exhibit all the angles. The design may be extended to any length of table, or made shorter at will.—J. Robson.

WORK FOR THE WEEK.

KITCHEN GARDEN.

The state of the weather prevents much being done in the open ground; but all tools may be sharpened and made ready for use. Cut Pea sticks, and prepare dung for forcing; shake it well to pieces when turned, and if it should be dry water it. If a constant succession of *Asparagus* is required, a bed should be made every fortnight till the end of March or beginning of April; a slight heat only is necessary. Keep the frames close, and cover up well till the shoots make their appearance, when they should have light and air. Seeds of the various sorts of *Capsicums* should now be sown in pots, which should be placed in a hotbed. If a sowing of *Carrots* has not yet been made it may now be put in on a slight hotbed, and covered with hoops and mats, or a frame, which may be removed in a month or six weeks if wanted for other purposes. If it is not convenient to prepare beds for *Potatoes* immediately, plant in small pots, and place them in any corner of the forcing house, where they can remain until they have made their appearance above ground; they should then be planted out, or be placed in a situation where they can receive sufficient light. I strongly urge the necessity of thoroughly turning up ground in which vegetable seeds are to be sown, and those who have allowed vacant ground to remain untouched should lose no opportunity of turning up the soil as deeply as possible, to expose it to the pulverising influence of frost; but while advising deep cultivation, I would not recommend bringing up the bottom if it

is poor and the supply of manure is short. After heavy rains and snow storms defective drainage will also be perceptible; a wet, badly-drained garden gives but poor supplies of vegetables in winter.

FRUIT GARDEN.

All pruning and nailing should be brought to a close as the weather will permit. Peaches and Apricots which have been taken from the walls to retard them until they are pruned, should not be left to the force of the wind, but be tied in bunches to the stronger wood till they are to be nailed up permanently. Fruit trees infested with moss should have as much as possible of it scraped off with a blunt knife or piece of iron hoop, and the parts well dusted with fresh lime, or limewash may be laid on with a brush. If the glaring appearance is objectionable, a mixture of soot may be given.

FLOWER GARDEN.

Those who have alterations to accomplish this spring in the way of planting and ground work, must lose no time when we have a favourable change in the weather. In planting large shrubs, it is an excellent practice to half fill the holes intended for the plant or tree with the rakings of the pleasure ground; this imparts to the plants an unusual degree of luxuriance, and of a most enduring character. Look over and correct the general outlines of ornamental plantations. Break into all hedge-like lines; form bold recesses where space will admit of it, and endeavour to create variety. The lines of irregular plantations or shrubberies should be corrected in this way at least every three years, as however well they may have been designed originally, the unequal growth of trees will, in some degree, militate against their first intention. Re-arrange masses of American plants; some of the more delicate Azaleas are frequently overgrown and injured by the grosser Rhododendrons. Biennials may be planted in flower borders or beds. Top-dressing Auriculas should be proceeded with on every favourable occasion. There are many kinds of manures recommended for top-dressing by different growers, but no manure is found equal to sheep dung, it produces a richness and brilliancy of colour in some varieties that cannot be surpassed—two parts of sheep manure in a very decomposed state, one part rich turfy loam, and one part decayed leaf mould; to this add a sufficient quantity of silver sand to colour it, and let it be well mixed previous to using. Having selected some of the strongest plants to commence with, proceed to examine them separately; turn each out of the pot in which it has been growing, with the ball of earth entire, to ascertain that the drainage is in proper order, and the earth free from worms and remove an inch of the surface soil from round the neck of the plant; a sharp knife is the proper instrument to perform this operation. Having removed the offsets fill round the neck of the plant with prepared compost, give the pot a gentle stroke on the bench, and a shake at the same time to level the soil. In planting the offsets it is necessary to divide them into three classes; those which are strong and well rooted may be potted singly in 60-sized pots; the weaker kinds that are moderately rooted are much better planted round the edge of the pots; and those with no roots may be planted similarly, but require to be kept in a warmer situation. The compost for offsets should not contain manure of any description, it should be composed of one part turfy loam, one part leaf mould, and one part peat earth, with a small portion of silver sand. In planting offsets without roots be careful to fasten them tightly at the neck; they strike under hand-glasses much more quickly than in frames. The planting of Ranunculuses should commence about the middle of February, as soon as the frost is out of the ground, and the surface in a fit state to rake. The beds must be made perfectly level, and the distance between the rows, 6 inches, should be marked on the wood edge; the bed is then ready for planting. It is a very important object to insure success in the cultivation of this flower, that the tubers be placed no deeper than 1½ inch; should they be either deeper or shallower a new and smaller one is formed at this depth to the serious injury of the variety. The best instrument to regulate the depth of the drill is a piece of smooth wood rather longer than the width of the bed, 5 or 6 inches broad, with notches 1½ inch deep at each end of one of the edges; the back of this board serves for levelling the surface, and by extending the cut edge across the bed the rows are marked. Then with a trowel scoop out the soil to the required depth, and to ascertain this press the notched end into the drill till it rests on the edges of the bed; plant the tubers by pressing them firmly into the soil, taking care not to break any of them, and cover them with the soil taken out of the drill. For strong-growing kinds ten tubers in a row are quite enough for a bed 4 feet wide; twelve or fourteen of the weaker kinds may be planted.

GREENHOUSE AND CONSERVATORY.

Luculia gratissima, when it has ceased flowering, should not get much water for a short time; pick off first the decayed heads of blossom, then cut the parts back moderately if they are loose and straggling, but if of a good shape stop all the shoots at a joint or two according to their strength. Do not venture to cut the plants back if they are not in good health, or without particular caution; they will probably not again break. Repot, top-dress, and clean all plants that require such attention; give air on every possible occasion, and no more fire heat than is sufficient to expel frost and damp.

STOVE.

Start such plants as Stephanotis, Dipladenias, Clerodendrons, both young and old plants, and recollect that a genial bottom heat is what they delight in. Do not at present excite Ixoras nor such plants as Franciscea macrophylla, which have set their bloom; but young plants of all kinds, to make the most of them, must be started immediately. Prepare tan or other fermenting material for renewing the bottom heat towards the beginning of March. Increase the moisture and temperature gradually as the days lengthen.

PITS AND FRAMES.

Propagate Dahlias by putting them in heat until they break, and then remove the young shoots, each of which should be potted in a small 60 or thumb-pot, and placed on a hotbed which has stood long enough to allow of the escape of the moist heat which would be fatal to the young plants; the frame should be kept as close as possible, and water given frequently, watching for any appearance of hot steam.—W. Keane.

DOINGS OF THE LAST WEEK.

On the 4th of February we lost sight of the snow, and were gladdened with a view of the green turf once more, the thorough disappearance of the white mantle being greatly owing to heavy rains on the preceding day. Altogether the week, up to the 4th, has been one of the darkest and mistiest we have seen, and though we have had a good proportion of damp days, the rainfall as a whole in this neighbourhood has as yet been very deficient, as our reservoirs of water too truly testify. By the 6th inst. we expect the frost will be out of the ground. Even on bare pastures, in many cases the soil is too hard a little beneath the surface to permit of the water from the melted snow passing freely away.

KITCHEN GARDEN.

Trenching and digging where practicable, and when time could be given, were here the chief work as preparatory for planting and sowing, as most early sowings are none the earlier now, and very early crops, such as Peas and Beans, are considerably injured. Sowings now, and repeated again during the month, will have the advancing sun to help them on. The whole appearance of the kitchen garden testifies to the appropriateness of the remarks lately as to having a good breadth of the hardier Greens, as they have stood the frost well.

Cabbages.—It is rather mortifying to read in the articles of coadjutors and contemporaries of the importance of filling up gaps in the main earliest quarters of Cabbages. Our fine-looking plants stood the first and most severe frosts well, and when the short partial thaw came we thought we were secure, and rejoiced; for what is better for an establishment than a fine quarter of early Cabbages? Now, though we protected them with Laurel branches, we find that the main crops are so much injured as scarcely to be worth keeping and filling up, and beds of young plants are very much injured, so that even young plants will be very scarce. Singularly enough rather small plants of Coleworts, grown chiefly for autumn use, and generally considered more tender than the Cabbages that furnish the first spring supply, have stood when the Cabbages have given way. This applies also to the young plants left in the seed-bed. They have wintered better than the supposed hardier kinds. As mentioned lately, those planted on a sloping bank to the north have stood the best of all, and we shall be glad of them, though they will not equal in size the fine fill-basket Cabbages from the main quarters. It will be interesting to know under what circumstances Cabbages have stood best. We suspect that the frost will have done most injury where the soil was richest and stiffest. The lowness and comparative warmth of the position would also aggravate the evil. Owing to altitude alone, we have often wholly escaped when gardens in

the valley have greatly suffered. We hope that in the light lands about Sandy and elsewhere there will be thousands upon thousands of healthy Cabbage plants, and that their sale at good prices will do a little to help the market gardeners in that district, as they suffered greatly owing to the drought of last summer.

We shall take up and pot some of our small plants that are left and put them in a frame with just the slightest bottom heat, so that the plants may have a number of fresh roots before being turned out. Many a plan must be tried to lessen the mischief which the long-continued frost has done us. We must also depend on the seedlings raised under glass, to be pricked-off and hardened-off before being turned out in the open ground.

Fortunately, Cauliflowers under hand-lights and other slight protection have stood well. The hand-lights had a little litter over them for a fortnight; Broccoli has also suffered much, except the hardiest kinds. Altogether we fear that vegetables will be scarce this season. We shall be glad to give more prominence than usual to Spinach, and that, Radishes, and Turnips must be obtained, if possible, earlier than usual.

Where seed *Peas* are no object, a nice supply for soups and even small dishes may be obtained by sowing the Peas thickly where there is a little heat and plenty of light, and cutting the tops over when 2 or 3 inches in height. At that size the soup will have much the flavour of Green Peas, as alluded to lately. Many a farmer might have delicious dishes of *Turnip tops* by making a slight hotbed, placing a frame over it, setting Swedish Turnips inside not too thickly, and cutting the tops when about 4 inches in height. If the tops are not higher the tubers will not be much injured for feeding stock. If preferred yellow instead of green, the tubers must be kept dark. Any warm place would do for this purpose.

Successions of Sea-kale, Rhubarb, Asparagus, Mushrooms, Potatoes, Radishes, &c., must be attended to, but these have lately received considerable attention. With a press of ground work and the retarding nature of the weather, it will not be easy to secure our usual forwardness in the kitchen-garden department.

FRUIT GARDEN.

Here, too, we are behind as to pruning and nailing, but we must try to expedite the first in all things except Peaches and Apricots. The bird question also often interferes with us as respects the smaller fruit. We hope that the Strawberry plants have not suffered. What we have examined, whether old or young, seem sound, owing to the protection of the snow. We have a strong belief that even the Cabbages most exposed, even of good size, would have withstood all the frost we have had, if it had been continuous. The partial and short thaws between made them more tender. We shall not be so forward as usual with Strawberries under glass, owing to alterations and fresh stagings in houses, but they look at present as if they would do well.

There could be no worse weather for *Peach trees in bloom*. We could do nothing more for them than keep them at a rather low temperature at night, give them a rise with air during the day, and with a thin flat board, used as a fan, make a slight breeze over the blooms to disperse the pollen gently. Partly owing to the sun of last season, the blooms seem strong and robust, and where thickly set we have thinned them considerably. In early forcing such thinning does much to insure a free healthy setting. Though heavy waterings are seldom now required, yet the roots should not be dry at such a period. The soil, therefore, should be examined, and all the more if the heating medium is close to the soil, or even under its level, the latter sometimes being the case in old houses. Of course we do not approve of any such plan, but many must make the best of what they have, instead of waiting until better means can be obtained.

Early *Vines* will also require much attention. Owing to the above causes ours will not be early, but have had the stems damped several times; though when a damp atmosphere can be secured there is less necessity for this syringing. We seldom syringe late Vines at all, either before or after they break. After they grow some length our water would not be clean enough. What moisture the leaves absorb from damp paths, &c., will be sure to be clean.

One great security for forward fruit houses in this and the late dark foggy weather is as much as possible to proportion heat to light, and then to give air, but mollified before it reaches the plants. A high moist temperature in such sunless weather is almost sure to be followed by watery spongy growth. Lowering the temperature five or more degrees, but so as to be safe, renders less atmospheric vapour necessary. Then, though as a general rule the vapour in the air of a house should be proportioned to the heat, it is easy to have too much of it when either Peaches or Vines are in bloom. The Peach will set best in a rather dry atmosphere, and though the air for Vines in a similar condition should not be so dry, neither should it approach saturation point. When the air is very dry, the little cap that encloses the parts of fructification is apt to bind them so closely that they cannot perform their functions. When the atmosphere is too saturated, the pollen is rendered lumpy and inert. For helping the pollen to act, in the case of Grapes, after trying brushes, fine feathers, &c., we have found nothing better than a dry clean hand drawn very gently along the bunch. For early Strawberries, too, we have found nothing better than drawing a dry hand through the trusses of bloom when they, too, were dry.

For all early houses with the *Vine roots* outside these roots must be protected from the cold, and if slightly warmed all the better. The simplest mode of doing this is to cover with litter, fern, &c., early enough in the autumn to prevent the heat of the summer stored in the soil escaping. Every day we see more and more the importance of planting Vines, &c., inside the house, though most of ours are planted outside; and even when we renew them we cannot help ourselves unless the whole internal arrangements as respects heating, &c., were altered, and these matters are not easily done. Of course our Vines are taken into the house through holes made on purpose, and one great disadvantage with us has ever been the rats finding their way to such holes and gnawing the stems, notwithstanding every possible means to deter and catch them. With one or two exceptions they have rarely meddled with the fruit. We would never think of so planting a new vinery. Under such circumstances the borders must be protected, and all the more in early houses. If fermenting material is used care should be taken that the heat is not too strong, and a trial stick, and, better still, a thermometer, should be inserted in the border 3 or 4 inches from the surface. From 65° to 80° would do no harm for short periods, but it is well not to exceed that. The average of 70° will tend much to encourage fibres to keep near the surface; the only disadvantage arising from such covering is that it should not be taken off soon, nor altogether at once, so as to give the border a chill. We have sometimes had the fruit of early Vines nearly ripe before removing it; and we know of many first-rate early Grape-growers, even when the Vine roots are not all outside, who seldom remove the covering from the borders until the berries colour. Of course with later houses such care is less necessary; but in medium houses as to earliness, many failures take place from giving a high temperature to the stems and branches whilst the roots are comparatively cold, and there is therefore no reciprocal action.

A number of years ago we met, when in the position of an under-gardener, with a striking example as to Vines partly under our charge, which we have never forgotten. The Vines were planted outside, and introduced through the front wall. In one year there was a splendid crop, ripening in August, without any care or covering being bestowed on the outside border. The next season it became very desirable that the same Vines should ripen their crop fully two months earlier. There was nothing done to the border outside, except a few inches of litter put on a narrow part of it in December, the rest being occupied with an artistic geometrical figure in Box, which it was felt very undesirable to disturb; otherwise the usual routine inside was gone through. The Vines broke well and showed well, but just as the bunches were lengthening and coming to the flowering period, a sudden check took place, the points of the bunches turned up, the central stem of the bunch became yellowish, many bunches became nothing better than tendrils, the little white globular dots in the shoots disappeared, there were no condensed drops of dew on the points of the foliage in the morning, and a very inferior crop, next thing to a failure, was obtained, instead of the grand crops before and afterwards. The Vines had used up the reserves stored in the past season, and the inert roots were unable to yield a further supply at a critical period, and the most valuable part suffered first. We believe if the roots had been close to the surface the failure would have been more complete. We thought then, and we are more confident of it now, if towards the end of October from 12 to 18 inches of dry litter had been placed securely on that border to the width of 15 or 18 feet, or if a month later some fermenting material had been placed over it to make and keep the surface warmish, so as to excite action in the roots, that no

such sudden check would have taken place. In such cases, then, let us so far teach by precept rather than example, and advise planters of Vines in houses to be forced at all early to plant inside, and have at least a portion of the roots inside, and even then to give some protection to the outside border in winter.—R. F.

TRADE CATALOGUES RECEIVED.

Archibald Henderson, Sion Nurssry, Thornton Heath, Croydon.—*Catalogue of Garden, Agricultural, and Flower Seeds.*

Little & Ballantyne, 44, English Street, Carlisle.—*Catalogue of Garden, Flower, and Farm Seeds, Implements, &c.*

William Thompson, Tavern Street, Ipswich.—*Descriptive Catalogue of Flower Seeds.*

Y. Strachan, 4, High Street, Wrexham.—*Catalogue of Agricultural, Vegetable, and Flower Seeds, &c.*

E. G. Henderson & Son, Wellington Road, St. John's Wood, London, N.W.—*Catalogue of Flower Seeds.*

F. & A. Dickson & Sons, 106, Eastgate Street, and Upton Nurseries, Chester.—*Catalogue of Vegetable and Flower Seeds.*

T. Bunyard & Sons, Maidstone and Ashford, Kent.—*Descriptive Catalogue of Vegetable, Flower, and Agricultural Seeds.*

S. Dixon & Co., 48A, Moorgate Street, London, E.C.—*Select List of Vegetable and Flower Seeds.*

James Dickson & Sons, 102, Eastgate Street, and Newton Nurseries, Chester.—*Catalogue of Vegetable and Flower Seeds.*—*Catalogue of Forest Trees, Fruit Trees, Shrubs, &c.*

TO CORRESPONDENTS.

Books (*T. E.*).—Johnston's "Physical Geography," Brown's "Forester's Guide."

Seeds (*H. H.*).—Any seedsman could obtain those you mention if any are in the market.

Kew Gardens (*A. B.*).—Write to Mr. Smith, the Curator.

Pronouncing Dictionary (*I. Barrett*).—No such dictionary of the names of plants is published.

Potato Culture (*T. Edmond*).—The pamphlet you name was written to *sell*. It is a tissue of ignorance.

Parsnips not Forked (*Crondall*).—Trench the ground two spades deep, and turn in manure with the bottom spit. If you enclose seven postage stamps with your address we will send you by post "The Rabbit Book."

Cucumbers.—"W. G. W." writes to us that "H. N." may probably obtain Tindall's No. 2 Cucumber seed of Mr. Milan, seedsman, Doncaster, or Fisher, Holmes, & Co., seedsmen, &c., Sheffield; but to make sure, "H. N." might send to the raiser, Mr. Tindall, gardener, Sprotborough Hall, Doncaster, where "No. 1" and "No. 2" are grown extensively. For Thomas Eads, our correspondent adds, Dale's Conqueror Cucumber seed is rather scarce; but, probably, if he applied to Mr. Thomas Dale, gardener to Mrs Tetley, Armley, Leeds, he would either supply him with seed or give the desired information.

How to Plant a Border (*J. W. B.*).—We do not plant borders, we merely criticise proposed plantieg. We presume you mean hardy annuals. The following would look well:—1, Silene pendula, or Saponaria calabrica; 2, Nemophila insignis; 3, Clarkia pulchella alba; 4, Viscaria oculata; 5, Erysimum Perofiskianum; 6, Blue Branching Larkspur.

Fowls' Dung for Roses (*W. G.*).—You had better mix the heavy soil with the light soil in which your Roses are growing, and do not apply manure until the flower-buds appear.

Leggy Zonal and Tricolor Pelargoniums (*G. G.*).—The only way to make them bushy plants will be to cut them down now, leaving to each shoot two or three eyes, and if you could encourage fresh growth by placing them in a house with a temperature of from 45° to 50° they would break more freely. The cuttings, inserted singly in 3-inch pots, would make good plants by bedding-out time if struck in a gentle hotbed, their growth encouraged, and then hardened well off by planting-out time. The "Garden Manual," Keane's "In-door Gardening," and Keane's "Out-door Gardening," price 1s. 6*d.* each, will suit you.

Yellow-flowering Annual (*A Poor Man*).—The best yellow-flowering annual, 9 inches to a foot in height, is Nasturtium Tom Thumb, yellow.

Turf Bare under Lime Trees (*Lime Trees*).—November is much too late to sow grass seeds, and to that we should attribute their bad growth. It is likely some of the seeds have vegetated, and that others will do so in spring, but we think your only plan will be to sow again early in April.

Zea Japonica variegata and Canna Treatment (*An Amateur*).—There is no particular treatment required by these plants in summer, for if there were their value for out-door decoration would be small. They require a situation protected from winds, but it should be open and warm. A rich light soil is most suitable, enriching it with leaf soil or well-rotted manure. Water should be plentifully given in dry weather, and sprinkle them overhead on the evenings of hot days. Shelter, however, is the main essential, for in exposed situations their leaves become torn and broken by the wind, and are then very unsightly.

Raising Roses from Seed (*W. C.*).—Rose seeds require time to vegetate, and had better be kept in tolerably moist cool soil before they are finally introduced into heat; then, when the outside shell of the seed is beginning to soften, sow thinly in boxes in a propagating house, being careful to keep the young shoots near the light when they first appear. The seeds should be mixed with soil and put in a cool moist place soon after gathering—when they are thoroughly ripened—and finally sown early in the spring—in February. Prick them out in boxes, pot off into small pots, giving shifts as required, and keep them in a cold frame the first year. Plant out the following spring in April or May. A few of the strongest and most forward plants might be planted in October the same year, if the seeds push quickly after being sown. As a general rule, so long as there is plenty of light and air, and the seedlings are not drawn up, it is better to give plenty of heat and push them on quickly. Mice are great enemies to the seed, and care must be taken in storing it in the first instance so as to be safe from their ravages.

Solanum capsicastrum Seedlings (*J. B.*).—We have our plants in a greenhouse, and they are loaded with bright red berries. Some are in 9-inch pots and grown as standards on stems 2 feet high, with very handsome heads 18 inches in diameter, and others are trained as pyramids. We advise you to turn the plants out of the pots in March, remove all the soil that comes away freely from the roots, and repot in 6-inch pots; or if pots of less size will hold the roots and balls without cramping, use them. Good drainage is necessary, and a compost of light turfy loam two parts, used rather rough, and one-third leaf soil or old decayed manure. Place the plants in a light airy position, keep them clear of green fly, and remove any irregularities of growth in April and again in June, shortening the long shoots so as to form compact plants. This is all the treatment we give our plants, and they could not do better. Repot them in June, or in May if the pots are full of roots. Do not give a large shift. For 11s. you may obtain a case of drawing instruments, except scales, of most stationers and of mathematical instrument makers. Instruments of inferior quality may be had for much less.

Climbers for South Wall (*Lancashire Subscriber*).—Berberidopsis corallina, Caprifolium luteum, Clematis Jackmanni, Glycine sinensis, Lardizabala biternata, Bignonia grandiflora, Clematis Standishi, C. Helena, Roses Gloire de Dijon and Maréchal Niel, Jasminum officinale grandiflorum, and Ceanothus floribundus. We do not advise the above, but would have all evergreens—viz., Ceanothus azureus, C. floribundus, C. integerrimus, Arbutus procera, Escallonia macrantha, E. montevidensis, Garrya elliptica, Ligustrum japonicum, Cratægus Pyracantha, Cotoneaster microphylla, Berberis stenophylla, and Magnolia grandiflora, Exmouth variety. These are shrubs, but suitable for walls or trellises against walls. For the trellis outside the front door we would have Cotoneaster microphylla and Pyracantha. There are no evergreen climbers that would suit, except Ivies.

Climbers for Conservatory (*Idem*).—Habrothamnus elegans, Hoya carnosa, Jasminum gracile, Kennedya inophylla floribunda, K. Marryattæ, Lapageria rosea, Mandevilla suaveolens, Passiflora Comte Nesselrode, P. Countess Ginglini, Tacsonia Van-Volxemi, Tecoma jasminoides, and Rhynchospermum jasminoides.

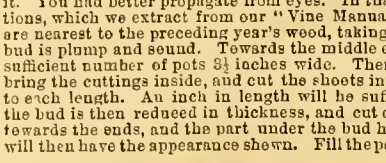
Expense of Making a Drive (*P. J. S.*).—We have paid 2s. 6*d.* per 10 feet for taking out a foot deep and throwing into carts, the usual price being 3*d.* per square yard, and for carting not more than a quarter of a mile 3*d.* per yard extra; or 6*d.* per yard altogether for reducing the ground 1 foot, which is 2s. 9*d.* per rod. The rubble will cost about 1s. per load, and the carting about 1s. 6*d.*, and will set 3 to 4 square yards, three loads being sufficient for two rods, consequently one rod will cost 3s. 9*d.*; and the metal, 4s. 3*d.* per 54 cubic feet, will cover two rods sufficiently, which with cartage will cost 7s. 3*d.*, or 3s. 7½*d.* per rod; in all 10s. 1½*d.* per rod.

Top-dressing Lawn (*Old Subscriber*).—If you now give the lawn a good top-dressing of lime and soil we do not see the necessity for the bone dust in March, though there is no objection to its use, as the lime, from mixing with the soil, will not have any injurious effect on the bone. If we gave the bone dust at all, which we would not this year, we should apply it all over. It is one of the best, if not the best, of manures for grass, and the most permanent.

Currant and Gooseberry Cuttings (*A Subscriber*).—Now is a good time to put in cuttings of these. Dig the ground well, and insert them 3 inches by a foot apart. Remove the eyes from the part inserted in the ground, which should be two-thirds the length of the cuttings.

Six Potatoes and Peas for Exhibition (*Idem*).—Victoria, Red-skinned Fleurball, Huntingdon, Berkshire Kidney, Webb's Imperial, and Dalmahoy, three kidney and three round kinds. Of Peas for September, Veitch's Perfection, Maclean's Premier, Ne plus Ultra, British Queen, Dwarf Green Mammoth, and Champion of England. Why grow so many?

Vine Cuttings (*New Beginner*).—If you employ cuttings, each should have two eyes, one to be above the surface, and the other 2 inches below it. You had better propagate from eyes. In that case follow these directions, which we extract from our "Vine Manual." Prefer the buds that are nearest to the preceding year's wood, taking care, however, that each bud is plump and sound. Towards the middle of December have ready a sufficient number of pots 3½ inches wide. Then, about New Year's-day, bring the cuttings inside, and cut the shoots into short lengths, one bud to each length. An inch in length will be sufficient. The part behind the bud is then reduced in thickness, and cut off in a slanting direction towards the ends, and the part under the bud horizontally. The cutting will then have the appearance shewn. Fill the pots nearly to the brim with soil, composed of fresh good loam, leaf mould, and very rotten dung, in equal parts, and with a small dibble insert one bud or eye in each pot quite overhead. Place the pots in a propagating-house, on a platform covered with sand, with a heat of 70°. At first, however, a temperature of 50° will be sufficient, and raise it 5° every week till the maximum is reached. A moist atmosphere should be kept up in order to cause the eyes to swell and break kindly. In a month or six weeks every bud will be breaking through the soil and forming roots. Keep the soil regularly moist, but not wet, for too much water would cause some to damp off. As the leaves begin to expand more water may be given.



Vine Leaves Unhealthy (*G. W. C.*).—We do not think any of the Vine leaves sent us have been infested with red spider, but they seem to have suffered from a current of cold air, or steam arising from sprinkling water on the heating medium whilst very hot. The leaves are too young for red spider, but they are so thin that we think if likely they will be attacked by it, therefore keep an outlook for it; and to ward off its attacks paint the hot-water pipes with sulphur brought to the consistency of paint by a solution of 4 ozs. of soft soap to a gallon of water, which will

cause the sulphur to adhere. By giving a little more heat now that the Muscats are flowering, and by attending to artificial impregnation, you may succeed in setting them fairly; this effected, you may grow tolerably well Muscats, Sweetwaters, and Black Hamburghs in the same house, but you would have a greater certainty of success if there were a division separating the Muscats from the Sweetwaters and Hamburghs. We can give you the recommendation you require for the Royal Horticultural Society's examination.

Cucumbers Deformed (*W. C. C.*).—The cause of your Cucumbers clubbing or having a knob at the end is they are seeding, which may be due to the stock you have being worn-out or old, or the plants may have been a long time in growth. We know of no remedy but fresh seed and young plants that have been grown without check. Perhaps a little more heat and atmospheric moisture would remedy the evil, giving weak liquid manure occasionally, as well as a top-dressing of rich light compost, and removing some of the old soil.

Mushroom Bed (*A. D., Herts*).—We cannot reply to your query unless you tell us where the bed is to be.

Osier Bed in a Damp Meadow (*Rosemary*).—If the expense is not too great it would be best to trench the ground before planting, at least it ought to be dug so as to turn the turf and other herbage upside down. Put in the Osier plants or cuttings as quickly as possible afterwards; both would grow by merely planting them on the turf, but not so well, and the rank herbage would be very troublesome in summer, and injure, if not choke, the small plants. Osier plants would be better than cuttings, but the latter will do; at the same time be careful to ensure planting only good varieties and such as are suitable for the desired purpose A strong coarse Willow is best suited for hampers and similar purposes, while a smaller one, tough and solid, with scarcely any pith in its centre, is the best for fine work. You had better consult some neighbouring basket-maker about the kind most likely to be wanted, as we know of some disappointment arising from not making such inquiries.

Avoiding Red Spider (——).—There is no better plan for preventing red spider appearing on the Strawberry plants in the vinery than using a moist atmosphere, washing the walls with sulphur behind the Strawberries, and also smearing the hot-water pipes with sulphur; the pipes or flues should not be warmer than about 170°. If there is a flue in the house, do not put sulphur at the warmest end. All fumes below that temperature will be safe, but beware of having strong fumes when the Vines are setting, and whilst the Grapes are small.

Bark Bed for Cuttings (*A Subscriber*).—Tanners' bark will do excellently for a bed with a frame over it for striking cuttings, &c., at the end of February, in March, and onwards. The bed should be made a fortnight previous to use in order that the tan may be sweet. To make a small striking house with a flue, you could not do better than adopt a modification of the plan recommended to "T. M.," at page 91, for a Cucumber house. We would surround the flue with open rubble—a light layer on the top of the flue—then washed gravel, then tan, sand, ashes, or cocoa-nut fibre.

Vines in Pots (*H. Foy*).—As to fruiting the Vines in pots, you will only succeed by keeping them in pots. Your proposed mode will answer very well. A bottom heat of from 70° to 80° will do after the Vines break, and for top heat from 60° to 65° until the bunches are pretty well formed; then when they begin to show bloom, raise the temperature gradually to 70°. We are not sure if we understand your object in placing the Vines in the hothouse. (*M.*).—It is not the fault of the Vines that they show no signs of breaking while standing on a stage in a dry house for ten weeks, with a night temperature of from 40° to 50°, and a day temperature of about 55°. You must moisten the canes of the Vines with a syringe, and keep the stage moist in sunny days, unless you place evaporating-basins on your pipes; then gradually increase the night temperature in a week to 55°, and in another fortnight to 60°, with a rise of from 5° to 15° in bright sunshine from sun heat, and with air given early. Then the Vines will soon show signs of moving. We cannot tell you how often to water at the roots, that will depend on the heat and the weather. Such Vines might want water every alternate day, and might not want it for ten days. The soil should not be dry. If pans are used for the pots, not more than from an eighth to a quarter of an inch of water should ever be in the pan. The surface soil should consist of rich mulching, and weak manure waterings should be given, especially after the Vines have broken and extended a couple of inches in length. Before breaking you may sprinkle the Vines twice or thrice a-day, but we have frequently broken Vines well without syringing them, merely by keeping a rather damp atmosphere. As to syringes, those having a round ball as a valve are the simplest and best.

Various (*Idem*).—We have no doubt that by having 2 or 3 inches on each side of the fire-bars, your fire will keep longer in. We have no faith in earthenware pipes for flues, unless there is a piece next the furnace of brick. Portland cement flues answer well, as Mr. Robson testifies, and we have seen them at Linton. We should consider one of the smallest-sized saddle or conical boilers ample for your place—say, if a saddle-back, 14 inches high, 14 inches wide, and 20 inches long, setting the boiler on a row of firebricks above the bars, and having the space for the bars from 9 to 10 inches wide; the boiler to be set as stated in answer to "T. N." to-day. Such a boiler would cost without fittings about 50*s.*, if of cast iron A cylinder cast iron boiler 18 inches high and 15 in diameter would cost about the same. There would be little to choose between them, but were we managing them ourselves, we could more easily make the saddle-back consume its own smoke.

Mushrooms in a Cellar (*J. F.*).—You can hardly have better advice than is contained in the article referred to at page 461, No. 497. It does not matter what the cellar is made of—rock, stone, or brick, or if it is even a dry place underground. The great advantage in all is the uniform heat. Your dry brick cellar will answer exceedingly well. If you have plenty of horse droppings, mixing with turfy loam in the proportions stated will be an advantage, but you can do without the loam if you cannot easily obtain it, only you must put on smaller layers at a time, and wait a little longer for spawning. The droppings from many horses, or from different stables, will be better than having to save material from one or two horses. Watering in winter will not be much needed, but when wanted we would use water at about 75°. In summer, to prevent any check, the water should be from 65° to 70° at lowest. Covering the beds with a little old hay will keep them more uniform in temperature and moisture in winter. It would not be needed in summer unless there were draughts through the cellar. In this case a covering would be an advantage.

Setting a Conical Boiler (*T. N.*).—We would never think of setting a conical boiler with a solid wall round it. We think the best plan is to place it at the height of one firebrick above the grate bars, and then leave a space of from 3 to 3½ inches round it, blocking the outlet from the top of the boiler inside, so that the smoke, flame, and heated air should go round the outside of the boiler before reaching the chimney. Setting your boiler on three firebricks on edge with an open space all round, would be better than with a solid wall next to the boiler, but on the whole we do not consider it to be so good as the above plan, though we have several times found it work well. All boilers, unless the bulk is inside a house, will lose heat unless surrounded by brickwork, but having a flue as above between the brickwork and boiler. If beyond that brickwork forming the flue there were another space, say 3 inches wide, for confined air, the heated bricks would tell on the boiler, and but little heat would extend to the brickwork beyond. In all such small boilers, however, after the heat has become strong, the continuance of heat with little fuel will depend on the careful use of the damper and ashpit door. Your 38-feet distance, where the small pipes connect the two houses out of doors, will also lose much heat unless these pipes be secured in a non-conducting medium, as dry sawdust, &c. The Lapageria rosea, being a strong plant, will succeed well planted out in the conservatory, if the place is well drained, room given for surface rather than deep rooting, and plenty of water without stagnation.

Names of Plants (*M. X. W.*).—2, Scolopendrium vulgare; 3, Selaginella Willdenovii; 4, Phymatodes vulgaris; 5, Pteris serrulata; 6, Adiantum hispidulum; 7, Saxifraga Fortunei. (*M. R.*).—1. Cyrtomium falcatum; 2, Nephrolepis tuberosa; 3, Onoclea sensibilis; 4, Scolopendrium vulgare.

POULTRY, BEE, AND PIGEON CHRONICLE.

RESULTS OF POULTRY-KEEPING.

According to your wish I send you a few particulars of my poultry-keeping. I had, hatched in April last year, twelve pullets and two cockerels (Golden-pencilled Hamburghs); the first pullet laid on October 23rd.

		No. of Eggs.
October	29th	7
November	5th	9
"	12th	13

"	24th	28
"	31st	34
January	7th	29
"	14th	28
		232

Two hundred and thirty-two eggs at nine a-shilling amount to nearly £1 6*s.* I obtained rather more, having sold some at 1½*d.* each, the remainder at nine a-shilling. I fed my fowls on peas at 1*d.* a-pound, and damaged wheat at 6*s.* a-measure (75 lbs.).

		s.	*d.*
Allowance per week,	6 lbs. of peas	0	6
"	12 lbs. of wheat	1	0
		1	6

You will remember a controversy in your Journal in 1861, when "E. C. C." disputed "Leighton's" statements, and perhaps there will be many who will say my fowls are not well fed; but I imagine their laying all through this frost, when neither grass nor grit was to be had, will prove the contrary. I calculate the cost of my fowls at about 2*s.* 6*d.* a-head to the time of their commencing laying.

	£	*s.*	*d.*
Eggs sold	1	6	0
Twelve weeks' Keep at 1*s.* 6*d.*	0	18	0
Profit	0	8	0

This may seem a small profit, but I can hear of no one having eggs; in fact, I am selling to people keeping four times the number of fowl I have, and they say they have not had an egg for four months. Perhaps your answer to "A. M." applies to me, and my success is attributable to hatching in April.—R. Wilson, *Wharf House, Ellesmere.*

[Save your March and April pullets by all means. They will put you in the satisfactory position you have occupied this year as regards eggs, but it is a pity to kill birds that have done so well, when they are only a year old. Sell them alive, or keep some of them to come in as layers when the pullets slacken next year. It is not all to have eggs in the winter; you should, and you can, manage to have them all the year round. —Eds.]

OUTRAGES ON PRIZE POULTRY.

The case of malicious mischief related by Mr. Cresswell is by no means a solitary instance of the risk our valuable poultry have to run during their journeyings to the various shows. I have now to relate a piece of villainy of a similar or, perhaps, even worse description. On the 13th of January I sent off my entries to the Aberdeen Show; among them were two valuable Game cocks, both having won me cups

at two of our principal shows. I naturally enough expected some notice would be taken of them by the Judges in giving their awards, but not even a commendation did they obtain, and why I could not surmise until their return home, when, to my horror and disgust, I found my best bird deprived of a portion of his tail and the longest flight feathers of one wing. The other bird was also mutilated in feather, but not to the same extent. It is evident that the mischief was done at the Show, for I have received a letter from a member of the Northern Poultry Club, in which, after offering me his sympathy, he states that my first bird which was penned he considered as likely a one as in the class, but on returning to this pen a few minutes later he found my bird had made a *partial moult*, and a party not far distant looking over the newly-arrived hampers, who, on being questioned, said he was looking for my other Game cock. Now how this party knew that I had more than one, or even one bird entered, is a mystery to me, unless he is a member of committee or had access to the Society's books, and it is a still greater mystery why no effort has been made to bring any suspicious party to justice.

Like Mr. Cresswell, I am prevented showing my bird for this season, besides being discomfited at the sight of a valuable bird suffering from the proceedings of one who must be depraved in the extreme, and free from all feeling and humanity.—J. W. Will, *Errol*.

WISBECH POULTRY, PIGEON, CANARY, AND RABBIT SHOW.

This, which I think was the first Exhibition of the kind held at Wisbech, took place on Wednesday and Thursday last, in the Public Hall, and was in every respect a signal success. Sometimes it requires a long time to popularise a poultry or a bird show. In some towns they take root at once and become recognised institutions, whilst in others they have to make a struggle for existence, and not unfrequently die-out from lack of support. It matters not how intrinsically excellent any exhibition may be if the taste of the public outside lie in another direction; and it is quite possible for a penny gaff, where may be seen "The Enchanted Stocking, hor the Blood-stained Bed-screw, followed by the Arlequin Dogs'-meat Man, hor Love in a Hiceberg," to reap a harvest in the same town where really interesting and instructive exhibitions can scarcely glean sufficient to pay rent and gas. Such does not appear to be the case at Wisbech, judging from the large attendance at the Show last week. It is under energetic, and what is better still, intelligent management, and I can congratulate the Canary fancy on one more fixture which is prepared to issue a good schedule, and which is under the supervision of a gentlemanly executive. The Hall was prettily decorated, with evergreens in pots interspersed here and there. It has frequently occurred to me, that in localities where the material is plentiful, a bird show combined with a winter garden or winter flower show would prove very attractive. Certainly it ought, and if good taste were exercised in the grouping of the plants and birds, a very charming spectacle might be produced.

The *Canaries* were placed on a stage draped with crimson, were well arranged and set in a good light, and though not so numerous as at other shows, contained more *bonâ fide* show birds than I have met with anywhere in proportion to the number staged. The Clear Yellow Norwich was an excellent class, Messrs. Cockle & Watson winning easily with a gem of a Jonque, a performance they repeated in the Clear Buffs; Moore & Wynn being second in each class. In Variegated Jonques Mr. Hawman's bird was first, though slightly deficient of a few minor feathers on one wing; but at this advanced stage of the season, birds which have been frequently shown, and, consequently, frequently in the tub, may be expected to be in not quite such faultless trim as some which have been kept back and laid-up in lavender. I think there is all the difference in the world between accidental loss and fraudulent trimming. Cockle & Watson were second with a grand heavily-marked bird, and also showed two splendid unevenly-marked birds in the Buffs, in which class Moore & Wynn were first and second. Mr. Hawman's bird was first in Crested Yellows, but it is taxing the discretionary power of a judge too much to send such a really good bird to a show in so dirty a condition. Both this class and the Crested Buffs were of extra quality. Lizards were remarkably fine, Mr. Harrison, and Cockle & Watson being the prizetakers with specimens of great merit. Mules were only moderate, the first-prize bird having some pretensions to quality, but the remainder only very so-so, too heavily and irregularly marked to have any chance with good-class birds. There are Mules and there are Mules. Cages of six were excellent, Cockle & Watson being first and second with six Jonques and six Mealies, very nice level birds. Messrs. Cockle & Watson made a gallant fight throughout, and it is something to lower the colours of such tried veterans as Moore & Wynn in the Clear Norwich classes. This, perhaps, would not have been the case if the Northampton firm had not suffered the loss at Ipswich which was announced in the advertising columns of the Journal. They had received an anonymous letter (I believe it was anonymous, a cowardly proceeding at best), to say they would see their stolen birds at Wisbech, and Mr. Wynne was at the Show on the *qui vive*. The so-called "stolen birds" to be seen at Wisbech, were the Clear Jonque and Clear Buff shown by Messrs. Cockle & Watson. Mr. Cockle was fortunately present and gave Mr. Wynn such thoroughly satisfactory evidence as to how and when he became possessed of them, as at once to clear up the matter and remove any impression as to the identity of the birds. I, too, have since received an anonymous letter on the subject, containing a most unworthy attempt to fix the stigma of direct theft on Messrs. Cockle & Watson, a fac-simile of which I enclose with these notes to the Editors of the Journal, with permission to publish it if they think it can answer any good purpose. But as the affair assumes very much the character of a libel, and may result in legal proceedings, the curiosity of the fancy may not be satisfied for a while. I will just add, that my anonymous correspondent hopes I will "tell all about it in the Journal," I have complied with his wish, and have placed his post card in Messrs. Cockle & Watson's hands.

I suppose this will be the last Show of the season which I shall report, for I have been obliged, with many regrets, to decline Carlisle, and I am afraid I shall not see the Palace Show this year. I am rather restless, but the moon is on the wane, and by the close of the week I hope to be in a resigned frame of mind. However (*balsamic word*), if I *should* be there ——— that dash indicates a spasm—and it will be on Saturday only, or not at all—any inquiries for "W. A. B." must be kindly made at the Secretary's table.—W. A. Blakston.

Dorkings.—1 and 2, G. Clarke, Long Sutton. *hc*, G. Cockle jun., Terrington St. John; J. Yates (2) Wisbech.

Bantams.—1, W. Adams, Ipswich. 2, S. S. Mossop, Long Sutton. *hc*, J. Blott, King's Lynn; Rev. F. Tearle, Gazely Vicarage, Newmarket. *c*, J. Blott; F. Lyon; T. Rogers, Walsall; E. Derry, Gedney; A. Stonar, Peterborough; T. Fenn.

Game.—1, H. E. Martin, Sculthorpe. 2, H. Snushall, Fleet Hargate, Wisbech. *hc*, W. Adams; H. E. Martin.. *c*, H. Snushall.

Cochins.—1, T. Rogers. 2, S. S. Mossop. *hc*, W. Boon. *c*, Mrs. Hines, Leverington.

Any other Variety.—1, T. Rogers. 2, Rev. W. H. James, Holbeach, Hurn. *hc*, W. Woodhouse, West Winch; Rev. W. H. James; Rev. A. Brook, Holbeach; W. K. Patrick (3) West Winch; Mrs. G. Phillips; C. W. Gibbs; S. Snarey, Wisbech; W. Catlack, jun. *c*, Mrs. Green, Leverington; Miss Hill, Wisbech; F. J. Bret, Downham.

Ducks.—1, Mrs. W. Ingram. 2, G. Cockle, jun.

Geese.—1 and 2, G. Cockle, jun.

Turkeys.—1, E. E. Derry. 2, M. Kew, Market Overton,

PIGEONS.

Carriers.—1, L. Wren, Lowestoft. 2, R. Payling, Peterborough. *hc*, A. Stonar.

Pouters.—1, R. Payling. 2, W. Woodhouse.

Tumblers.—1 and 2, W. Woodhouse. *hc*, H. Cox, Wisbech. *c*, Misses E. and A. Wren.

Runts.—1, H. Boyer.

Barbs.—1 and 2, J. Blott

Dragoons.—1, A. W. Wren. 2, J. E. Crofts, Blyth.

Any other Variety.—1, H. Snushall (Hyacinths). 2, T. C. Marshall (Magpies). *c*, F. N. Taylor, Leverington (Turbits); J. E. Crofts (Black Magpies); J. Simmons, Wisbech (Trumpeters); R. Payling (Yellow Turbits).

Rabbits.—1, J. Priestly, Long Sutton (Lop-eared Fawn Buck). 2, J. Bree, New Walsoken. *c*, W. T. Streader, Wisbech (Doe); H. Tuck; A. Langley, Downham Market (Fawn Doe); J. Priestly (Lop-eared Yellow Doe).

CAGE BIRDS.

Norwich.—*Clear Yellow.*—1, Cockle & Watson, Terrington St. John. 2, Moore and Wynn, Northampton. *vhc*, Cockle & Watson; Moore & Wynn; W. Cooke, Norwich. *hc*, T. Fenn, Ipswich (3). *c*, T. Irons, Northampton. *Clear Buff.*—1, Cockle & Watson. 2, Moore & Wynn. *hc*, W. Cooke (2); T. Fenn (2). *c*, T. Irons; Moore & Wynn.

Evenly Marked or Variegated Yellow.—1, R. Hawman, Middlesbrough. 2, Cockle & Watson. *vhc*, Moore & Wynn (2). *hc*, Cockle & Watson. *c*, T. Fenn (2).

Evenly Marked or Variegated Buff.—1 and 2, Moore & Wynn. *vhc*, Cockle & Watson (2). *c*, T. Irons; W. Cooke.

Crested.—*Yellow.*—1, R. Hawman. 2, Moore & Wynn. *vhc*, T. Fenn. *c*, T. Irons; Cockle & Watson; Moore & Wynn; T. Fenn. *Buff.*—1, Moore & Wynn. 2, Cockle & Watson. *vhc*, Moore & Wynn. *hc*, T. Fenn (2).

Green.—1, Mrs. Bothamley, Wisbech. 2, Moore & Wynn. *vhc*, Cockle and Watson; T. Fenn.

Jonque Cinnamon.—1 and 2, T. Irons. *c*, Cockle & Watson.

Buff Cinnamon.—1, Moore & Wynn. 2, T. Irons. *vhc*, T. Irons; Moore and Wynn.

Lizard.—*Golden-spangled.*—1, Cockle & Watson. 2, J. N. Harrison, Belper. *vhc*, R. Hawman; Cockle & Watson. *c*, S. Benn, Lynn. *Silver-spangled.*—1, J. N. Harrison. 2, Cockle & Watson. *vhc*, R. Hawman; Cockle & Watson. *hc*, J. Cuthbertson, Lynn.

Cage of Six Canaries.—1 and 2, Cockle & Watson. *c*, Cockle & Watson; Miss Upwood, Terrington St. Clements.

Goldfinch or Linnet Mule.—1, H. J. Ims, Bloomsbury, London (Goldfinch Mule). 2, T. Fenn (Yellow). *hc*, H. J. Ims (Goldfinch Mule); T. Fenn (Buff).

Goldfinch.—1, J. N. Harrison. 2, Miss Upwood. *c*, J. T. Manerief, Wisbech.

Bullfinch.—1 and 2, Cockle & Watson.

Parrot.—1, W. Sharred. 2, Mrs. Blake. *c*, H. Smith; T. F. Parker; W. Newman; S. Snarey.

Judges.—*Poultry:* Mr. W. B. Tegetmeier, London. *Singing Birds:* Mr. W. A. Blakston, Sunderland.

WOLVERHAMPTON POULTRY SHOW.

This Show was noquestionably good, and most probably, all things considered, the best that has yet taken place at Wolverhampton, though the arrangements in the limited space of the Agricultural Hall necessitated a double tier of poultry in all cases instead of a single one, a circumstance which detracted considerably from the beauty and easy inspection of the various classes.

The *Dorking* cock class stood first on the list, but these birds as a whole were not by any means of equal quality to such as have competed at the previous Wolverhampton annual meetings, most of them showing great want of condition. The hens were decidedly a better class throughout, the first-prize being a grand pen, well shown, of single-combed dark-feathered birds; the second a rosy-combed pen, equally praiseworthy, had not one of the hens been loose-combed. In fact, the latter were the larger of the two in point of frame. The third-prize pen, belonging to the Rev. E. Bartrum, was also of good character. Decidedly in all varieties the *Cochins* shown at Wolverhampton this season quite outvied those ever yet exhibited in the locality, being admirable as a class. The unusually good quality of the hens throughout was a common remark of fanciers of these breeds; no doubt the

greater advance in the season caused most of the adult hens to exhibit in far better condition than at late meetings. Some excellent Dark *Brahmas* were shown, the hens again having the superiority as to general condition. *Houdans*, almost unknown hitherto at this Show, were very good, and in excellent feather. The *Crève-Cœurs* were decidedly better than we have seen for some time past, great care being now taken in the selection of brood stock, so as to produce the square well-knit bird, so much prized on the table. The *Spanish* classes have been always well filled at the Wolverhampton Show, and were not less so this season; the havoc the late severe frost has made with the combs and constitution of the various otherwise capital specimens competing this year, was, however, painfully apparent. In *Game* fowls most of our best breeders competed; Messrs. Chaloner, Dyas, Fletcher, Laming, Matthew, and various others sending first-rate pens. Mr. Matthew took both first prizes for pairs of Game, and Mr. Fletcher the first prize and silver cup for the best pen of Game, with a Black Red hen. The *Hamburghs* throughout were superior to those hitherto shown at Wolverhampton, the Spangled being the better represented. Game *Bantams* were evidently mostly the worse for over-exhibition, a few really good pens being sent in so bad a state of health that success was hopeless. The cup pen of White Bantams was better than most of those recently shown; but perhaps the greatest novelty and curiosity in the whole collection was Mr. W. W. Boulton's new variety of Cuckoo Bantams. They were veritable Bantams, and of the most perfect Cuckoo colour imaginable. In the Variety class, La Flèche were first, Golden Polands second, and Malays third. Out of an entry in this class of sixteen pens, all present, only four pens remained unnoticed. The largest classes in the Show were the Selling classes, and many of these entries were really good, being even far superior to those of the usual classes, consequently the sales were very general.

Turkeys, *Geese*, and *Ducks* were all good, in fact, at our largest shows it is not customary to meet with anything better. In the variety Duck class, Mandarins were the first-prizetakers, and Pintails second; Carolinas, Mandarins, and Buenos Ayrean Ducks of first-rate quality being compelled to submit to no higher position than a highly commended. Mr. J. Dixon, of Bradford, and Mr. E. Hewitt, of Birmingham, officiated conjointly as Judges of Poultry; the Pigeon prizes being awarded by Mr. W. B. Tegetmeier, of London.

Dorkings.—*Cocks.*—1, G. Whitcombe, Gloucester. 2, Hon. J. Massy, Husbands Bosworth. 3, J. L. Lowndes, Hartwell. *Hens.*—1, G. Whitcombe. 2, Hon. H. Fitzwilliam, Wentworth Woodhouse. 3, Rev. E. Bartrum, Great Berkhamstead. *hc*, Miss F. A. Meek, Balcombe; J. Watts, King's Heath, Birmingham; G. Clarke, jun., Long Sutton. *c*, J. Horton, jun., Shirley.

Cochin-China (Cinnamon and Buff).—*Cocks.*—1, J. Watts. 2, H. Lloyd, jun., Handsworth. 3, J. Sichel, Timperley. *hc*, W. A. Burnell, Southwell; W. A. Taylor, Manchester (2); R. Dawson, Beverley. *c*, Earl of Bradford, Weston; Lady E. Moreton, Tortworth Court; E. Thomas, Didsbury. *Hens.*—1, W. A. Taylor. 2, Mrs. Wilkin, Bootle, Carnforth. 3, J. Watts. *hc*, W. A. Burnell; J. H. Dawes, Moseley; W. A. Taylor; A. Darby; J. Sichel. *c*, W. Masland, Milverton.

Cochin-China (Brown and Partridge).—*Cock.*—1, G. Lamb, Compton. 2, W. A. Taylor. 3, J. White, Whitley. *hc*, E. Tudman, Whitchurch; Rev. R. L. Story, Lockington; E. Tudman. *Hens.*—1, W. A. Taylor. 2, E. Tudman. 3, G. Lamb. *hc*, J. Stephens, Walsall; R. B. Wood, Uttoxeter; W. A. Taylor; E. Tudman.

Cochin-China (White).—1, J. Sichel. 2, R. Brown, Cheadle Hulme. 3, R. Chase, Birmingham. *hc*, Mrs. Waddell, West Derby; C. F. Herrieff, Banbury; J. Sichel.

Brahmas (Dark).—*Cocks.*—1, Rev. E. Alder, Etwall. 2, J. Robinson, Garstang. 3, G. A. Stephens, Dublin. *hc*, G. Bradford, Hanley; G. F. Whitehouse, King's Heath; Lady E. Moreton; J. Hill, Brentwood; O. E. Cresswell, Feltham; H. B. Morrell, Clyro; J. Sichel; J. Watts. *Hens.*—1 and Cup, G. E. Gettins. 2, T. F. Ansdell, St. Helens. 3, Dr. Holmes, Chesterfield. *hc*, Lady E. Moreton; H. B. Morrell (2); G. Bradford, Hanley; C. Taylor, Gloucester. *c*, R. Bailey, Etwall; J. H. Pickles, Southport.

Brahmas (Light).—1, D. Causer, Erdington. 2, A. O. Worthington, Burton. 3, Rev. N. J. Ridley, Newbury. *hc*, T. A. Dean, Moreton-on-Lugg; F. Crock, Forest Hill. *c*, J. R. Rodbard, Bristol; W. T. Storer, Brewood; T. A. Dean.

Houdans.—*Cock.*—1 and 3, R. B. Wood. 2, Mrs. J. Cross, Appleby, Brigg. *hc*, Hon. J. Massy. *c*, F. Bennett, Shiffnal. *Hens*—1, R. W. Wood. 2, R. B. Wood. 3, Hills & Co., Brighton. *hc*, J. Drewry, Burton-on-Trent.

Crève-Cœur.—*Cock.*—1 and Cup, Mrs. J. Cross. 2, J. Sichel. 3, H. Beldon. *hc*, Mrs. E. Williams, Berriew; C. Morris, Grassendale; Rev. N. J. Ridley; C. H. Smith, Radcliffe-on-Trent. *Hens.*—1, J. K. Fowler. 2, C. Morris. 3, J. Sichel. *hc*, Hon. H. Fitzwilliam; H. Beldon.

Spanish.—1, E. Jackson, Finchfield. 2, J. Walker, Wolverhampton. 3, H. F. Cooper, Walsall. *hc*, J. F. Sillitoe, Wolverhampton (2); J. Walker; R. Davies, Chester; M. Egginton, Wolverhampton; E. Jackson; H. Beldon.

Game.—*Black or Brown Red.—Cocks.*—1, S. Matthew. 2, W. M. Sowerbutts, Nantwich. 3, C. Chaloner, Steetly. *hc*, Hon. and Rev. F. Dutton, Burford; C. Chaloner; J. Mason, Worcester (Black Red); W. E. Oakeley, Atherstone (2); W. H. Cooke, Worcester (Black); A. B. Dyas, Madeley; E. C. Gilbert, Penkridge. *Any Variety except Black or Brown Reds.—Cocks.*—1, S. Matthew (Duckwing). 2, Master W. Fletcher, Stoneclough (Duckwing). 3, J. Laming, Spalding (Duckwing). *hc*, C. Chaloner (2); E. Bell, Burton (Duckwing); W. J. Cope, Barnsley (Duckwing); J. Mitchell, Moseley (Duckwing); W. Dunning, Newport (Duckwing); J. Laming (Duckwing). *Any Variety.—Hens.*—1 and Cup, W. Fletcher. 2, C. Chaloner. 3, J. Laming (Black Red). *hc*, E. Beß; S. Matthew; W. E. Oakeley; W. Dunning. *c*, W. H. Cooke (Black Red); J. Laming.

Hamburghs (Gold or Silver-spangled).—*Cocks.*—1, H. Beldon. 2, J. Buckley, Ashton-under-Lyne. 3, T. Boulton (Gold). *hc*, T. M. Derry, Gidney (Silver); Rev. W. Sergeantson (Silver); T. Blakeman, Tettenhall (Gold); T. Boulton (Gold); G. F. Whitehouse, King's Heath (Gold). *c*, T. Boulton (Gold). *Hens.*—1 and Cup, H. Beldon. 2, N. Marlor, Denton (Gold). 3, J. Buckley (Gold).

Hamburghs (Gold or Silver-pencilled).—*Cocks.*—1, J. H. Arnold, Moseley (Gold). 2, H. Pickles, Earby. 3, W. M. Mann, Kendal (Silver). *hc*, H. Beldon. *Hens.*—1, W. M. Mann (Silver-pencilled). 2, H. Pickles, jun., Earby. 3, H. Beldon.

Hamburghs (Black).—1 and 3, T. Walker, jun. 2, Rev. W. Sergeantson. *hc*, R. Bailey; W. A. Taylor.

Bantams.—*Game.*—1, E. Cambridge, Bristol. 2, R. Swift, Southwell. 3, C. Chaloner. *hc*, H. Coley, jun., Neachley Hall; J. Watts; Master Swindell, Oldswinford. *White. Clean-legged.*—1 and Cup, S. & R. Ashton. 2, H. Beldon. 3, Rev. F. Tearle, Gazeley. *hc*, Lady E. Moreton; S. & R. Ashton. *c*, J. Watts; S. & R. Ashton. *Any variety except Game and White.*—1, W. W. Boulton, Beverley (Cuckoo Bantams). 2, E. Cambridge (Black). 3, M. Leno, Dunstable (Laced). *hc*, J. Sichel; H. Beldon; Mrs. A. Woodcock, Leicester (Japanese); H. Draycott, Humberstone (Japanese). *c*, H. Pickles, jun. (Black); Bell and Thorpe, Stratford-on-Avon (Black); J. Watts (Silver-laced); Rev. G. F. Hodson, Bridgwater; W. W. Boulton (Cuckoo Bantams).

Any other Variety.—1, Hon. C. Fitzwilliam (La Flèche). 2, T. Dean, Keighley (Polands). 3, W. B. Payne, Shrewsbury (Malay). *hc*, G. A. Stephens, Dublin; Rev. A. G. Brooke, Shrawardine (Malay); W. Silvester, Sheffield (Gold Polands); H. Beldon; Rev. N. J. Ridley (White Leghorns); J. Watts (Sultans); Miss C. E. Palmer, Lighthorne, Warwick (Scotch Dumpies); W. A. Taylor (Cuckoo Cochins). *c*, Rev. G. F. Hodson (Malay).

Selling Class.—*Cocks.*—1, R. Chase (White Cochin). 2, H. Yardley, Birmingham. 3, C. Morris (Crève-Cœur). *hc*, L. Poynton, Congleton (Dark Brahma); W. A. Burnell (Buff Cochin); J. Lord (Buff Cochin); W. Swann, Erdington (Buff Cochin); J. R. Rodbard (Spanish); J. Mansell, Longton (Spanish); W. H. L. Clare, Twycross (Duckwing); Capt. W. G. Webb, Elford (Black Game); W. J. Cope (Game) (2); W. E. Oakeley (Black Reds); W. Speakman, Nantwich (Gold Hamburghs); F. Bennett, Shiffnal (Black Hamburghs); R. M. Lord (Dark Brahma); Mrs. A. Williamson (Light Brahma and White Cochin); Hon. J. Massy (Houdan); J. H. Brodwell (Dorking); J. Forsyth, Tettenhall (Black Red); J. Watts; W. Gamon, Chester. *c*, Rev. N. J. Ridley (Crève-Cœur); D. Lane, Hardwick (Houdan); W. A. Taylor; J. L. Lowndes (Dorking). *Hens.*—1, J. Sichel (Olive Cochin). 2, T. Sherratt, Knypersley (Dark Brahmas). 3, H. Bagshawe, Uttoxeter. *hc*, F. Bennett (Black Hamburgh); W. Birch, Barnacle (Black Hamburghs); J. Palmer, Longford (Brown and Partridge Cochins); C. Morriss (Crève-Cœur); W. E. Oakeley (Black Reds); J. Forsyth (Black Reds); J. Clews, Walsall (Spanish); E. Jackson, Finchfield; J. Watts (2); H. Yardley (2). *c*, W. A. Taylor; W. A. Burnell (Buff Cochins); W. Masland (Cochins); T. M. Derry (Buff Cochins); G. Newdegate (Game Piles); J. Bishop, Eyton; R. M. Lord (Dark Brahmas); F. Bennett (Dark Brahmas); J. Robinson, Garstang.

Turkeys.—1, Rev. N. J. Ridley. 2, J. Watts. *hc*, Earl of Bradford; F. E. Richardson; C. F. Clark, Perton.

Geese.—1, Rev. G. Hustler, Stillingfleet. 2, J. Watts. *hc*, R. Beckett, Hartford; J. K. Fowler; S. H. Stott, Rochdale.

Ducks.—*Aylesbury.*—1 and 2, J. K. Fowler. *c*, J. Williams, Walk-upon-Dearne. *Rouen.*—1, J. K. Fowler. 2, W. Gamon. *hc*, C. F. Clark; Miss Davies, Chester; J. White; R. Heigh, Himley; J. White; S. H. Stott. *Any other Variety.*—1, J. Watts (Mandarins). 2, Rev. W. Sergeantson, *hc*, M. Leno (Mandarins); S. and R. Ashton (Mandarins); J. E. Morriss, Elmsdale (Mandarins); G. S. Saimsbury, Devizes (Black East Indian); Rev. W. Sergeantson.

PIGEONS.

Tumblers.—1, H. Yardley. 2, J. Ford, London. *hc*, J. Ford; J. Wilson, Aston (2).

Carriers.—1, F. Smith, Birmingham. 2, H. Yardley. *hc*, F. Smith; W. H. Mitchell. *c*, J. Watts.

Pouters.—1 and 2, W. Gamon. *hc*, Mrs. Waddell, West Derby.

Fantails.—1, H. Yardley. 2, Rev. W. Sergeantson. *hc*, J. F. Loversidge, Newark (2).

Antwerps.—1, H. R. Wright, Hockley. 2, T. Morris, Wolverhampton. *hc*, H. Yardley (2); W. H. Mitchell; C. Langman, Bilston.

Dragoons.—1, W. H. Mitchell. 2, F. Graham, Birkenhead. *c*, Rev. H. J. Stokes, Grindon (2); H. Allsopp, Birmingham; J. Watts (2); F. Graham.

Jacobins.—1, W. E. Easten, Hull. 2, H. Yardley. *c*, C. F. Clark.

Nuns.—1, T. A. Dean, Moreton-on-Lugg. 2, S. A. Cooper, Walsall. *c*, F. Graham; W. E. Easten; H. Yardley.

Any other Variety.—1, F. Smith (Barbs). 2, S. A. Wyllie, East Moulsey (Runts). 3, J. Watts (Norwegian). *hc*, H. Yardley (2); T. J. Ford, Stourbridge; S. A. Wyllie, East Moulsey (Florentines).

NANTWICH POULTRY SHOW.

(*From Correspondents.*)

The eleventh annual Exhibition was held on the 3rd and 4th inst. in the Town Hall, a place well adapted for such an exhibition. The Secretary has a thoroughly good working Committee, and is well supported in the district, the Hall being filled with visiters. The only fault I have to find with the Society is that it restricts the competition to exhibitors residing within a radius of thirteen miles from Nantwich. When I asked the question, Why restrict your exhibitors to so confined a district, when you have birds fit to compete against the world? the reason given was, Our subscribers would not give anything if they thought there was a chance of its leaving the neighbourhood. Now this is penny wise and pound foolish, for at the Show just held, if exhibitors had been drawn from a distance the Society would have been benefited, and several of the exhibitors would have obtained many pounds for their birds, there being Game fowls entered here at £5 5*s.* each that would have been snapped up at once. This is a great loss; besides, when open, competition gives the inhabitants a chance to compare their improvements with those of other districts.

The Show might be almost called an exhibition of *Game*, and so good were the birds that I have not seen a collection like it since the great Liverpool Sweepstakes years. Commencing with a class for old birds of Black or Brown Reds, a Black Red had the cup; it was of most beautiful symmetry, with the real distinct orange hackle and saddle, and beautiful violet red shoulder coverts—one that ought to be sought after for a brood cock. Second came a Brown Red, nearly, if not quite, up to the standard, having a good, long, strong, snake head, and a dark-streaked breast, with the beautiful lemon-straw back and lemon saddle; shoulder coverts dark brown maroon. The third-prize bird was perfect in feather, his only fault being that he was not quite large enough. There are but few shows at which he would not have stood first, but the collection at Nantwich was so extraordinarily good that he had to be placed third. The next class was for stags of any colour, for the Society's silver cup. Here Brown Reds carried all before them, although there were some grand Black Reds and Duckwings, but the Judge had such a collection placed before him on a raised daïs, that he had to stand for some considerable time to admire them as a whole before he could bring himself to discard any, saying they all ought to have a cup, but he most reluctantly commenced to handle and tick off for points some of the finest cockerels shown this year. When, however, we consider this is the neighbourhood whence all our winning yards of late years have sprung, their excellence is not so surprising. The cup cockerel was of that grand type of which

a few examples were seen about fifteen years ago, but which has been a'most lost, owing to breeding with the Black Reds and Duckwings. A Brown Red has almost a standard for shape different from all other Game—much stronger in head and neck, large dark eye, thick from breast to back, broad, strong shoulders, with a width in front that is hardly admissible in other breeds of Game. In the cup bird we had all that was wanted—symmetry and colour to perfection; the second and third-prize birds were very little behind; indeed, there was a slight difference of opinion which ought to have been first out of the three. Many of the highly-commended birds were fit to win anywhere. Nantwich is the place I should recommend to all who want fresh blood in Brown Reds.

The class for adult Black Reds was hardly up to the mark, there being a want of colour and style; adult Brown Reds were good, the only fault being they were a little too heavy. Duckwings and Piles were not so good as I could have desired, most of the Duckwings being soft and loose in feather, with the exception of the first-prize bird, which had hard, short, good feathers, and colours beautifully blended. The Piles were not quite clear enough in their colours. Game hens and Black and Brown Reds were a most extraordinary collection. No class of hens at any other show during the past year has come near them. Black Reds, good in style and colour, were first; they were all we want—free from red on the wings, and without the least pencilling on the ends of their wings. The second and third prizes went to Brown Reds, fine in colour, with good black, bold eyes, and of excellent symmetry. Black Red cockerels were not up to the standard. Of Brown Red chickens (cockerel and pullet), the first, second, and third-prize birds would be treasures to any Brown Red breeder; all I can say is they were perfection in colours and of fine shape, leaving no room for improvement.

Turkeys were poor; of *Geese*, one pen was up to the mark; *Ducks* were poor; *Spanish* nowhere; *Dorkings*, *Cochins*, *Brahmas*, and *Hamburghs* miserable.

In the *Pigeons* there was a falling-off both in quantity and quality as compared with previous years. The supposed cause was that one exhibitor, as in former years, had borrowed, or was supposed to have borrowed, many birds from a dealer, and the presumed fact caused many fanciers to withhold their support, the Show being really confined to members and exhibiters within a radius of thirteen miles from the Town Hall. I trust if this assumed fact is correct numerous fanciers in the district will cause this assumption to be properly ventilated, and will again prove how creditably they can support the exertions of the Committee as in years of yore.

The *Cage Birds* were a show in themselves. *Rabbits* were only indifferent.

Spanish.—1, R. Hulse, Winsford. Equal 1, J. Siddorn, Over Lane.
Bantams.—1, W. Woolley, Bunbury. *Sweepstakes.*—1, A. Jackson. *Game.*—1, Miss Cawley. 2, R. Ashley. 3, Miss E. Church, Nantwich.
Dorkings.—1, W. B. Etches, Woodhouse.
Cochin-China.—1, J. G. Pearson, Drayton.
Brahma-Pootra.—1, J. Walker, Keele. 2, J. G. Pearson.
Game.—*Cock.*—Cup, R. Ashley. 2, Galley & Willett, Nantwich. 3, J. Platt, Swanlow. *Hen.*—1, J. Platt. 2, R. Ashley. Equal 2, Galley & Willett. *vhc*, G. F. Ward, Wrenbury. *hc*, J. Platt. *Cockerel.*—Cup, Galley & Willett. 2 and 3, W. Sowerbutts, Nantwich. *vhc*, R. Ashley (2). *hc*, T. Burgess, Burleydam. *Black Reds.*—1, T. Burgess. *Chickens.*—1, W. Miller, Wyburnbury. 2, R. Ashley. *Brown Reds.*—1, Galley & Willet. 2, T. Burgess. *Chickens.*—1, Galley and Willet. 2, R. Ashley. 3, T. Burgess. The whole class Very Highly Commended. *Any other Variety.*—1, J. Platt. 2 and *vhc*, R. Ashley. 3, J. Wilkinson, Norbury. *hc*, Miss Sadler, Whitchurch. *Sweepstake.*—1, G. F. Ward.
Hamburghs.—*Pencilled*—1, Mrs. Flyn, Hardingswood. 2, W. Speakman, Doddington. *Spangled.*—1, Mrs Flyn. 2, C. Steele, Crewe.
Selling Class.—1, G. F. Ward.
Turkeys.—1, Miss Roberts, Bunbury Rectory.
Geese.—1, Galley & Willett. 2, T. Whittington, Batherton.
Ducks.—*Aylesbury.*—1, Mrs. M. Hornby, Darnhall. *Rouen*—1, J. Platt. *Any other Variety.*—1, Rev. — Merideth, Burleydam.

Pigeons.—*Carriers.*—1, W. Woolley, Bunbury. 2, J. Chesters, Nantwich. *hc*, S. Cliff, Nantwich. *Dragoons.*—1 and *hc*, S. Cliff. 2, Messrs. Prince & Pass, Nantwich. *Pouters.*—1, J. Chesters. *Barbs.*—1 and 2, Messrs. Prince & Pass. *Tumblers.*—1 and 2, A. J. Boote, Weston. *Fantails.*—1 and *hc*, J. Chesters. 2, Messrs. Prince & Pass. *Jacobins.*—1 and 2, J. Chesters. *Trumpeters.*—1, A. J. Boote. 2, J. Chesters. *Nuns.*—2, J. Chesters. *Owls.*—1, E. S. Nixson, Nantwich. 2, Messrs. Prince & Pass. *Turbits.*—2, J. Chesters. *Any Variety.*—1, J. Chesters (Runts). 2, W. Woolley (Satinettes). *Doves.*—1, Miss J. H. Nixson, Nantwich. 2, J. Hockenhull, Nantwich. *Selling Class.*—1, A. J. Boote.

Singing Birds.—Canaries.—*Yellow.*—1 and 2, S. Williamson, Nantwich. *Buff.*—1 and 2, S. Williamson. *Crested.*—1 and 2, S. Williamson. *Norwich.*—1, S. Williamson. 2, H. Bowyer, Nantwich. *Any Variety.*—1, S. Williamson. Brown Linnets.—1, H. Timmis, Walgherton. 2, R. Williamson, Nantwich. Goldfinches.—1 and 2, S. Williamson. Skylarks.—1 and 2, R. Williamson. Bullfinches.—1, S. Williamson. 2, H. Timmis.

Rabbits.—1, Mrs. Forster, Nantwich, 11½ lbs. 2, F. P. Johnson, Nantwich, 10½ lbs.

Judges.—*Poultry:* Mr. Douglas, Clumber Park, Worksop; *Pigeons, Cage Birds, and Rabbits:* Mr. Ridpeth, Outwood Hall, Handforth.

Poultry Show at Northampton.—In order to encourage the Spanish and Dorking fanciers, I have opened subscription lists for two silver cups as extra prizes in the above classes. Any exhibiters or admirers of these breeds wishing to subscribe towards the cups will please forward their subscriptions to me as early as convenient.—F. Sabbage, 17, *Broad Street, Northampton.*

Balds and Beards.—Mr. W. J. Woodhouse says he will show a pen of his Baldheads and Beards at the National Peristeronic Society's Show, to be held at the Crystal Palace on the 14th of February, and will give to any person £50 sterling if he can show a pen like them for quality.

SELKIRK POULTRY SHOW.

At this Show, held on the 1st and 2nd inst., there were upwards of 250 entries of poultry and Pigeons. The awards were as follow:—

Spanish.—1 and Cup, D. Waugh, Melrose. 2, J. Oliver, Choppington New Row, Morpeth. 3, H. Wilkinson, Earby.
Dorkings.—1, D. Gellatly, Meigle. 2, J. Logan, Eastshield, Carnwath. 3, W. G. Mulligan, Springfield, Belfast. *Chickens.*—1, D. Gellatly, Meigle. 2, W. Reekie, Selkirk. 3, W. Bearpark, Ainderby Steeple. *hc*, Z. H. Heys, Barrhead.
Cochin-China.—1, R. Hime, Bedlington, Morpeth. 2, J. Pollock, Busby, Glasgow. 3, Com. G. F. Lyon, Kirkmichael, Dumfries. *hc*, W. Linton, Selkirk.
Brahma Pootra.—1, J. Cowman, Whitehaven. 2, W. Brownlee, Kirkcaldy. 3, Com. G. F. Lyon. *hc*, W. G. Mulligan; J. Cowman; Miss Drummond, Megginch Castle, Errol; D. Rutherford, Selkirk.
Hamburghs.—*Golden-pencilled.*—1, A. Pratt, Kirkcaldy. 2 and 3, W. R. Park, Abbotsmeadow, Melrose. *hc*, Lady M. Scott, Bowhill; J. Nicholson, jun., Carlisle; H. Pickles, jun. *c*, R. Blakeburn, Choppington New Row. *Silver-pencilled.*—1 and 2, H. Pickles, jun. 3, R. Blakeburn. *Golden-spangled.*—1, J. Ogden, Hollinwood. 2, A. Heatlie, Selkirk. 3, R. Dickson, Selkirk. *c*, H. Pickles, jun. *Silver-spangled.*—1 and Cup, Ashton & Booth, Broadbottom, Mottram. 2, W. R. Park, Melrose. 3, G. J. Campbell, New Pitsligo. *hc*, J. Nicholson, jun., Carlisle.
Game (Any variety).—1 and Cup, J. W. Will, Errol. 2, D. Hardie, Priesthaugh. 3, A. Ormiston, Kelso (Duckwings). *Chickens.*—1, A. Dewar, Linton, Cluny. 2, T. W. Mitchell, Perth. 3, W. Chalmers, Leslie. *hc*, J. Blair, Blairnigone, Dollar (Brown Red).
Game Bantams.—*Black or Brown Red.*—1, G. Hall, Kendal. 2, Z. H. Heys, Barrhead. 3, G. Todd, Sunderland. *hc*, D. Hardie (Black Red); H. Kirsopp, Bathgate (Black Red); W. Brownlee, Kirkcaldy (Black Red); A. C. Lang, Selkirk (Black Red). *c*, W. Goddard, Earlston (Black Red). *Any other Variety.*—1, J. Craw, Jedburgh (Duckwing). 2, Bellingham & Gill, Woodfield, Burnley. 3, J. Stable, Great Driffield (Pile). *hc*, W. Brownlee (Duckwing); Bellingham and Gill; G. Macmillan, Jedburgh (Pile). *c*, G. Stalker, West Sleekburn (Duckwing).
Bantams.—*Any other variety than Game.*—1, Master A. Frew, Sinclairtown (Pine Silver-laced). 2, T. C. Harrison, Hull. 3, J. Archibald, Earlston (Japanese). *hc*, H. Yardley, Birmingham (Gold-laced); H. Pickles, jun. (Black). *Any Variety.*—*Cock.*—1, Bellingham & Gill. 2, J. Ferry, Cowpen, Morpeth (Brown Red). 3, W. Scott, Jedburgh (Duckwing). *hc*, E. Douglas, Selkirk; W. Brown, Selkirk (Black Red).
Any other Variety.—1, W. R. Park (Crêve-Cœur) 2, T. Dean, Keighley, Yorkshire (Polands). 3, W. Bearpark (Silver Polands). *hc*, Z. H. Heys; G. Todd, Sunderland (Crêve-Cœur); H. Pickles, jun. (Polands); J. Logan (Houdans and Black Hamburghs).
Barndoor Fowls.—1, W. Reekie, Selkirk. 2, J. Scott, Newhall, Lilliesleaf. 3, Com. G. F. Lyon.
Ducks.—*Aylesbury.*—1, Com. G. F. Lyon. 2, D. Hardie. 3, J. Scott, Newhall. *hc*, R. Dickie, Burnside, Alva; A. Hoggart, Leslie; G. Dryden, Selkirk. *Rouen.*—1 and 3, D. Hardie. 2, W. G. Mulligan.
Cottagers' Class (Any variety).—1, D. Waugh, Melrose (Spanish). 2, J. Beattie, Selkirk (Brahma Pootra). 3, J. Laidlaw, Langholm (Spanish). *hc*, T. Brown, Melrose (Spanish); R. Hogg, Selkirk (Silver-spangled); T. Hogg, Selkirk (Silver-spangled); T. Smith, Selkirk (Golden-pencilled); W. Riddell, Selkirk (Dorking).
Selling Class.—1, W. Linton, Selkirk (Crêve-Cœur). 2, T. W. Mitchell, Perth (Brown Red Game). 3, D. Gellatly, Meigle (Dorking). *hc*, W. Grice, Bootle. *c*, J. Craw, Jedburgh (Duckwing).

PIGEONS.

Tumblers (Any variety).—1, A. Johnstone, Bathgate. 2, W. Goddard, Earlston (Almonds) *hc*, A. Fairbairn, Whitmuir, Selkirk.
Carriers.—2, H. Yardley. *hc*, M'Gill Skinner, Edinburgh.
Fantails.—1 and 2, A. Crosbie. *hc*, J. G. Spence, Edinburgh.
Pouters.—1 and Medal, M'Gill Skinner. 2, J. Fairley, Edinburgh.
Jacobins.—1, W. E. Easton, Hull. 2, H. Yardley. *hc*, J. G. Spence, Edinburgh; W. R. & H. O. Blenkinsop, Newcastle-on-Tyne.
Nuns.—1, W. E. Easton. 2, W. Bearpark. *hc*, T. Dickson, Selkirk.
Owls.—1, W. Goddard. 2, J. G. Spence. *hc*, A. Crosbie, Melrose; H. Yardley.
Turbits.—1, W. E. Easton. 2, Miss B. P. Frew, Kirkcaldy. *hc*, A. Crosbie.
Any other Variety.—1 and *c*, A. Crosbie (Letz and Black Trumpeters). 2, W. Goddard (Ice). *hc*, H. Yardley; A. Johnstone, Bathgate; W. Goddard, Earlston (Austrian Pouters); Miss R. C. Frew (Magpies).
Selling Class.—1, J. Simson, Fauldshope (Turbits). 2, M'Gill Skinner (Black Trumpeters). 3, W. R. & H. O. Blenkinsop. *hc*, W. Inglis, Selkirk (Red Pouters); A. Crosbie (Fantails). *c*, A. Johnstone (Fantails).

Judge.—Mr. Richard Teebay, Fulwood, Preston.

PRIZE LISTS FOR CARRIER PIGEONS.

Having until last autumn been absent from England for some years, I am surprised at the prize lists for Carriers not being so extensive, I may say, as they were. This is to be regretted, but more especially the system now in force, except at one or two large shows, of exhibiting in pairs. Now, every Carrier fancier knows this is a very difficult thing to accomplish, for I believe, as a rule, no fancier breeds from two Blacks or two Duns. There may be exceptions of course. Then, again, it does not follow that the two best show birds would be those you match to breed from, and you cannot risk the fight that will take place on putting odd birds unmated into the same pen. If committees cannot afford to increase the lists, why not divide the sum into prizes for single cocks and single hens, as with Pouters? I am sure that exhibiting in pairs deters many from showing. I should be glad if some of your readers would give their views on this point. My own idea is, that the pair-system does not tend to the advantage of either committees or exhibitors.—F. C. Hassard.

THE FANTAIL PIGEON.

In No. 502 there is an article on the Fantail Pigeon, which, after enumerating the many points good birds of this breed ought to possess, leaves out one of the most important, that of

size. As regards this, they cannot be too small; and I disagree with the writer as to their being hardy birds, as the finer the quality the more tender they are. As we are referred to the illustration, it is full of errors. The head is far too round, it ought to be long, and the neck about half the thickness at the part where the head is set on. As the body is in profile, and the tail more than three-quarter view, it is twisted—a grave fault in a Fantail. Taking it altogether, I should consider the bird figured exceedingly coarse, and of but little value. The number of feathers in the tail of a high-bred small Fantail seldom exceeds thirty-two. The shaking of the neck is a point, and is indispensable. Why should Blacks, Blues, and Silvers have pearl eyes, and Yellows and Reds be doubtful? What is right for one is right for the other, at least so says—PRIZETAKER.

UNITED KINGDOM RABBIT CLUB.

IN reference to the remarks made in your paper of January 26th by Mr. M. Millington, of York, the Nottingham Fancy Rabbit Society fully appreciates, and will be most happy in assisting to form, a "United Kingdom Rabbit Club," and to have a paid Secretary, to fix upon the different classes, likewise the number of prizes, and to correspond with each of the poultry show committees throughout the United Kingdom. We are confident of this, that if Rabbit fanciers were to unite throughout the United Kingdom it would put an end to all jealousy. I may also add, on behalf of the Nottingham Fancy Rabbit Society, that we shall be glad to co-operate in any scheme such as that suggested by Mr. Millington.—JOSEPH PARKER, *Secretary, Woodlark Inn, Nottingham.*

COLCHESTER AND PORTSMOUTH RABBIT PRIZES.

IN answer to Mr. Millington's observation, "I am surprised the fancy-variety men who have written so much upon the injustice done to the variety classes at most shows, should now praise the one-sided list from Colchester, where only £3 are offered for the Lops in one class, £9 going to the fancy varieties"—that is, Himalaya, Angora, and any other variety—I cannot see anything one-sided about this, but I consider it one-sided when about five times as great a sum is offered to one breed as to another, as at York and Portsmouth. There are about six distinct breeds of the fancy kinds that are shown, and to compare them as *one* class to the Lops is quite unreasonable.

Mr. Millington looks at the value of the Lops, but Committees do not—they generally put the classes as they think they will pay best. Now, at the York Show, of which Mr. Millington was a judge and manager, they offered to the Lops the sum of £17 10*s.* in five classes, and had forty-five entries at 2*s.* each, making £4 10*s.* To the ill-used fancy varieties they only offered £4 15*s.* (calling the medal £1), in only three classes, and had forty-five entries, paying them £4 10*s.*, being within 5*s.* of the prizes offered.

I suppose the Colchester Committee have seen this, and because they have put the fancy kinds upon the same footing as the Lops, and they are praised for it, Mr. Millington calls us one-sided, and maintains that the prize-schedule of Portsmouth is the best. Now, at Portsmouth they have four or five classes for Lops—first prize, 15*s.*; second, 10*s.*; and two silver cups; entrance 2*s.* per pen. The varieties have to be content with a paltry prize of 10*s.*; entrance 2*s.*, just the same as for Lops, for which one breed about eight times the value of prizes is offered as to the six breeds of fancy varieties. Lastly, Mr. Millington says the Colchester Committee will find out their mistake when the entries close; to which I reply, we must wait till both shows are over and compare the entries.—JAS. BOYLE, JUN., *Blackburn.*

P.S.—A few words in answer to Mr. Millington's note on my Rabbit kindling after the York Show. Mine is not the only case; I have had letters from Mr. E. E. M. Royd and Mr. A. L. Rawstron, whose Rabbits kindled as did mine. Mr. Millington says, that I in "careful haste put both Rabbits together." I defy anyone to put two Rabbits in a compartment measuring 13 inches long, 6½ inches broad, and 8 inches deep, which are the dimensions of each of the four compartments in which the Himalayans were sent. I hear the fancy kinds have to be shown singly next year.—J. B.

SILVER CUPS AT THE CRYSTAL PALACE CANARY SHOW.

MR. STANSFIELD writes me that he is suffering from an attack of perpendicularity of the capillary tubes on the summit of his cranium consequent upon my call to him to "wire in." Let me assure him the symptoms are not very dangerous. My hair often stands on end, in fact it has a habit of doing so when what there is left of it looks in the glass and sees how the frost and snow have altered its colour. Speaking technically, I should say it has "run" very much. I have read his note incorrectly. The idea he wished to convey was, not that he had received one hundred subscriptions, but had about one hundred applications to make. Happy man! £3 3*s.* to raise among one hundred fanciers, all eager to contribute to the cup—exactly 7½*d.* and 6-25ths of a farthing each; say 1*s.* 3*d.*, and there will be a cup for the "Any other variety of Mule" also, a class which, I repeat, is to a naturalist one of the most remarkable in the Show. Mr. Bailey (Purfleet Bailey, not he of Thirsk), what are you about that you are not gleaning for a cup for the Foreign Bird classes? "Wire in," there is plenty of time.—W. A. BLAKSTON.

FOUL BROOD.

FROM reading in page 77 the article of your esteemed correspondent "R. S." I have been induced to make the following remarks. First, I have two hives which were supplied with dried combs taken from a foul-brood stock five and six years ago, which have given on an average 80 lbs. of comb annually from that time, and which are and have remained free from foul brood ever since. Notwithstanding the difference of opinion as to the cause of foul brood, we are all agreed that its consequences are fatal unless a speedy manipulation of the hive takes place, and that its fatal effects fall on the young larvæ. Now I may ask, What is the disease? Is it an epidemic caused by the inhalation of some disease-germ, or by inoculation, commencing externally, eating its way inwardly until the intestines are reached, thus causing death and corruption? Or is it caused by fungi and the germs of disease being equally spread in wax and honey, or by improper food acting in some way prejudicially to the larvæ? This last cause is in my opinion the most likely one—nay, in fact the effects point to this. If we examine the brood of a diseased hive we can at once recognise a marked difference in its appearance from that of a healthy stock, having a more corpulent appearance, and in many cases signs of flatulency; at all events the larvæ when under the microscope present the appearance of having suffered, if they possess that sense, as their internal organs are wasted away and look as if they had burst, whilst in healthy larvæ at the same stage these organs can all be completely traced. These experiments were, however, made for my own amusement, and no notes being taken at the time I cannot now explain them satisfactorily.

As to the question whether unsealed honey, or sealed and unsealed honey mixed, produce fermentation, this I answer in the positive; and on the same ground do I condemn the removal of unsealed combs from a hive and extracting honey with the centrifugal machine. In every case in which I have drained the honey from a diseased hive it has shown signs of more or less fermentation, and in every case where this honey has been given to bees it has produced disease.

In regard to the case described by "A RENFREWSHIRE BEE-KEEPER," and remarked on by "R. S.," I have noticed it often, and in some instances have observed the lid of the cell lifted off, and the mouldy substance showing round the edge. The practice of preserving such is by no means uncommon in this locality, but I regret to say where it is practised the apiary is more diseased than otherwise. With regard to weak hives mentioned by "R. S." as having dead bees in spring or autumn, any ill effects which may follow do not in my opinion arise in any way from the dead bees, but rather from what honey they contain having undergone a chemical change in the same manner as described by "A RENFREWSHIRE BEE-KEEPER."

I had a chat with an old bee-keeper of fifty years' standing, who maintained that the disease originated from not mixing whiskey with their food; so long as he knew this practised no disease was known. The cure of foul brood by medicine is, I think, difficult, but perhaps not impossible.—A LANARKSHIRE BEE-KEEPER.

OUR LETTER BOX.

BOOKS (*J. C.*).—"The Poultry-keepers' Manual" has coloured plates, price 5*s.* "The Poultry Book for the Many" is 6*d.* If you enclose sixty-six stamps with your address, and four extra for postage of the first, and one stamp for postage of the second, you can have both free by post from our office.

DORKING LAYING WITH DIFFICULTY (*C. M.*).—Do you mean three eggs per month or per week? She sits on the nest till she has laid her egg, and it is probable the roughness of the shell causes the difficulty in doing so; at any rate it is not a natural state. We advise you to give castor oil, a tablespoonful every other day, and to use Beily's pills. Give barley-meal or ground oats with the pickings and scraps. Discontinue maize-meal and buckwheat, both are too fattening.

BLACK BANTAM COCK'S TAIL (*Amateur*).—It is not an advantage for a Game Bantam cock to carry his tail erect, nor to be very full-feathered. The tail should be scanty of feathers, and be carried rather down than otherwise. We should prefer No. 1.

Marking Poultry (*Lemon Buff*).—You do not say whether you want a mark to be recognised only by yourself, or whether it may be visible to all. In the latter case nothing is better than a piece of coloured cloth sewn round the leg, different colours marking different broods. If it is to be a private mark, it may be on the beak or eyelid, or, easier still, marked with a red-hot iron in the web of the wing—thus, .. ∴ ∴ ⁖ : , and so on. Being made with a red-hot instrument the holes do not fill up, and are not to be seen unless they are looked for by some one who knows where they are.

Spanish Cocks' Faces (*Young Beginner*).—If the cock is suffering from a cauliflower face, as it is called, on account of its resemblance to that vegetable, the best thing we know of is powdered alum, as it penetrates into the cracks and dries them up. We know no work that treats of these points. The face will never heal till you are able to keep it dry; the weeping turns it brown wherever it touches.

Crossing Fowls for Table Use (*Irish Subscriber*).—If you wish for choice poultry, keep pure Dorkings. If you cross at all, cross with Brahmas, by putting a Brahma cock to Dorking hens. It is not well to put Houdans with Dorkings, because they are non-sitters. The Houdan is a better table fowl than the Brahma.

Breeding Turkeys (*H. F.*).—Turkeys, like all poultry, should lay on the ground. The hens begin laying from the middle of March to the end of April and later. It is of no use to keep a pair of Turkeys. Having satisfied yourself his services are no longer necessary, separate them. If you leave them together it is probable you will have no eggs, because he will kill the hen. It is an unwise thing to keep a cock unless you have several hens.

Dorking Pullets' Legs Paralysed (*Mrs. B*).—The pullet is probably suffering from an injury to the back, and it will be some time before she recovers. You need not keep her before the fire. Put her in a dry, covered place free from draught and damp, and supply her with Sussex meal and some sods of growing grass, cut with plenty of earth. The supply of eggs will depend on the age of the fowls. All the pullets will lay within a fortnight if they have passed the age of six months, excepting the Polands, they lay later. Brahma and Cochin pullets lay earlier than others. It is not in the nature of hens to lay in the winter.

Barrow Poultry Show.—In the class for Game cockerels, the cup was awarded to Mr. J. Mason, St. John's, Worcester.

Plymouth Poultry Show (*M. Deacon*).—Write to the Secretary again, and say that if the birds or the money be not sent to you within a week you will instruct your solicitor to proceed in the County Court for their recovery.

Malay Prizes at Northampton.—Mr. William Humphreys, 30, Newland, Northampton, Secretary to the Show, will be very pleased to receive contributions and devote the same to the object mentioned by the Rev. A. G. Brooke, and will duly advertise the special prize in this Journal if one be subscribed for before the entries close, March 1st.

Egg in Egg (*J. Palmer*).—This monstrosity frequently occurs.

Combs of Dorkings (*An Inquirer*).—The comb of a Dorking hen should fall over; that of a cock should be upright. It is a grave fault for it to turn even at the back. Eggs may be left with impunity during a day in summer, but if a hen deserts them in such weather as this for twelve hours,

"All the king's horses and all the king's men
Can't set Humpty Dumpty up again."

Brahma's Laying Intermitted (*C. W. L.*).—It is more than probable your fowls are egg-bound. Pull out a tail feather, dip it in oil till it is perfectly saturated, then pass it down the egg-passage till it meet the egg. It will give relief, and the hen will make an effort; do not attempt to assist her, but continue to lubricate the passage. Their food is too fattening; give ground oats slaked with water morning and evening, maize and barley alternately for the midday meal.

Incubator (*Dorking*),—We cannot give you any relative information. We never knew anyone who had purchased an incubator who did not find that the money was thrown away.

Fowls Hunchbacked (*G. B.*).—You are mistaken when you say your birds are of the purest strain, if by that you mean the best strain. If they have any pretension at all to breed, it goes back for some years, because although it is not uncommon for Hamburghs and Polands when they are in-bred to produce hunchbacked chickens, still they are the exceptions. If you have four all affected in that way, they are either hopelessly out-bred, or they are the drafts from some yard sadly in want of fresh blood. There is no cure for it, and it is always hereditary. You must not breed from them.

Dubbing (*Poussin*). — Apply to Messrs. Baily, 113, Mount Street, Grosvenor Square.

Hive for Taking Honey in Supers (*E. D.*).—Payne's improved cottage hive, described in pages 7 and 8 of the last edition of "Bee-keeping for the Many," but of somewhat larger dimensions, is cheap and will answer your purpose very well, as will also the Stewarton hive, manufactured by Mr. R. Eaglesham, Stewarton, Ayrshire. The Woodbury frame hive is the best adapted for scientific and experimental bee-keeping, and may be seen and bought at Messrs. Neighbours', 149, Regent Street, and 127, High Holborn, London.

Woodbury Hives (*W. O.*).—Apply to Messrs. Neighbour, Regent Street. "Bee-keeping" will suit you; you can have it free by post from our office if you enclose five post-office stamps with your address.

Rabbit Injured (*Anthony*).—Hold her by the hind legs and strike her at the back of the head, it deprives the animal of sensation instantly.

Treatment of Parrots (*Paterfamilias*).—As to food, cut stale bread in slices and pour warm water over it, let it soak awhile, squeeze it as dry as possible, then allow it to absorb as much fresh-boiled milk as it will without being very moist. This is the staple food; sometimes give biscuits treated in the same way. Indian corn is good, but must be boiled first and drained of the water; nuts occasionally, and fruit in season. Fill their pan with food. As to drink, give clean water, and in summer a bath, which, if they can be induced to take it, is a great benefit, and makes them look nicely. The constant pecking the feathers is owing to the bird having, or having had, bones given it. We have known Parrots pluck themselves entirely bare, as if for the spit, owing to meat and bones, which ought never to be given them, as they cause irritation of the skin and heat the bird. The bird is a vegetable-eater, not a meat-eater. If it were summer a slight sprinkling of tepid water from a fine watering-pot or syringe would comfort the skin, but that would not do now. In regard to teaching, have the bird alone with you, and repeat the same word or phrase over and over again. If you cover its cage when receiving its lesson it will listen all the more attentively. Whistle the same tune in like manner. Keep the bird warm, and give it as much sunshine as possible. A cold winter kills hundreds of Parrots. With gentleness and kindness you may effect much. Unfortunately children and servants often tease or frighten them; both are bad. Sifted gravel it should have. Keep bird and cage very clean. Mind the Parrot's feet are carefully washed from impurities. Get the bird's confidence, and you will succeed with your pet, and find it a pleasure.

REMARKS.

1st.—Overcast in the morning, drizzle throughout the day, with a wet fog.
2nd.—Cloudy throughout the day.
3rd.—Overcast in morning, rain during the day, ceasing at 7 P.M.
4th.—Cloudy all day except at noon, rain between 7 and 8 P.M.
5th.—Fair in morning, southerly gale begun at noon, rain in evening, but fine after 8 P.M.
6th.—Beautiful day, both warm and bright.
7th.—Cloudy throughout, with heavy rain after noon.

Erratum.—The mean dry bulb reading for last week was misprinted as 36.1, it should have been 30.7.

The week just ending has been much warmer than any other of the present year, but even it is very little above the average, and the soil remains remarkably cold. The prevalence of cloud, which has attracted so much attention, still continues.—G. J. Symons.

COVENT GARDEN MARKET.—February 8.

Owing to the favourable change in the weather we have had a better supply of out-door produce, and the improvement noticed last week has been maintained. Of choice vegetables the quantity is still limited, although we have been able to procure some from St. Malo and that neighbourhood. Pears comprise Beurré de Rance, Easter Beurré, Ne Plus Meuris, and Jean de Witte; Apples—Ribston Pippin, Nonpareil, Court of Wick, Newtown Pippin, and others. The Potato trade report large supplies.

POULTRY MARKET.—February 8.

Moderate supply and sluggish trade. There has been buying for transmission to Paris, but there are still difficulties in getting goods into the city if they are intended for sale.

From observations taken near London during forty-three years, the average day temperature of the week is 46.1°, and its night temperature 31.2°. The greatest heat was 59°, on the 16th, 1847; and the lowest cold 2°, on the 17th, 1855. The greatest fall of rain was 0.51 inch.

ORCHARD HOUSE MANAGEMENT.

THERE is no garden structure so easily managed, and yet so full of interest, as the orchard house. It has this advantage also—it can be erected at less expense than most other glazed structures. Let it not be implied from this that a cheap structure is the best, or even the cheapest in the end. If the work is substantial it will require a very small outlay to keep it in repair during the first twenty-five years; whereas a house built of inferior materials and ill-constructed will perhaps require considerable outlay after the first eight or ten years.

The original idea of an orchard house was a glass erection of the most primitive construction, to protect Peaches, Nectarines, Pears, and other fruit trees from spring frosts while in blossom, and to ripen the fruit better and at a less cost than can be done on walls. Whether fruit can be grown in an orchard house at a less cost I cannot say, but I am inclined to think that it can; that it can be grown of better quality in most cases there can be little doubt. Another obvious advantage is, that a crop of fruit can be obtained the second season after the house is built, with a small expenditure for trees. I have purchased Peach and Nectarine trees one year from the bud, and after growing them one season in pots, they have borne a crop of from one to two dozen of fine fruit. The trees must be carefully attended to during the growing period, but it is interesting work, and after a few lessons can be performed by unskilled hands as well as by the properly-trained gardener. Most gardeners are aware that to have a wall of Peach and Nectarine trees in good health and fertility, much care and attention are required; and after sufficient experience of a practical nature with both systems I can safely say that working in the orchard house is a much more agreeable occupation than attending to the requirements of wall trees.

The orchard house, to be effectual, should be heated in some way; hot-water pipes are the best means of applying artificial heat. The house here is a span-roofed structure, 24 feet wide by 12 high, and four rows of 4-inch pipes are required to keep out the frost during the time the blossoms are expanding. About the first week in January we manage to give the glass and woodwork a thorough washing; four hundred pots of Strawberries are then brought in and placed on a shelf, which extends all round the house near to the glass. Peaches and Nectarines are also brought in, and arranged more closely than they will ultimately be during the growing period. Some of the varieties do not set their fruit freely; these, with some of the others, will be removed out of doors to ripen the fruit after all danger from frost is over, and it is well not to risk the trees out of doors until the end of May or the beginning of June. I placed a number of pot trees of Peaches and Nectarines out of doors in a somewhat sheltered position in the first week of May last year, when the fruit were as large as horse beans; frosty nights set in, and 6° of frost on the 9th of May blackened and destroyed all the young fruit. The heating medium is not only required on frosty nights, but is equally useful in cold dull weather, as the circulation of air which it creates facilitates the setting of the fruit. As soon as this is fairly set ply the syringe vigorously amongst the trees night and morning, and on the first appearance of aphides give the house a good "dressing" with tobacco smoke, and continue to do so until they are destroyed.

Water the trees with clear water until the end of May, when occasional waterings with weak liquid manure will be beneficial. The trees ought also to be fed by surface-dressings applied for the first time in June. A good mixture for this purpose consists of half-decayed horse droppings, cow manure, and loam in equal proportions; a couple of handsful of this spread over the surface of each pot, and lightly pressed down, will soon bring the roots to the surface. This surface-dressing may be applied two or three times at intervals of three weeks. From the middle of May until the fruit is gathered all fruit trees in pots require abundant supplies of water at the roots, as if they suffer from want of that most necessary element at this time there will be no fine fruit. The same remark applies to Strawberries in pots; as soon as their trusses of flowers are thrown up it is not easy to overwater them. Some growers stand the pots in saucers which are kept full of water; this saves labour in watering, but I fancy the fruit is not so good.

Only the best sorts of Strawberries are grown in the orchard house, and quality is preferred to quantity. There are appliances here for forcing, but those who have no other glass structure should grow a few of Black Prince in the earliest corner, and Frogmore Late Pine as the best late sort. Numerous varieties have been tried here, but the best as yet are President, La Constante, Sir Harry, British Queen, Mr. Radclyffe, Dr. Hogg, and Frogmore Late Pine. I think highly of Lucas and Souvenir de Kieff; they were both first-rate out of doors last year, and will be tried in pots in the orchard house this season.

It is advisable to take the Strawberry plants out of the orchard house as fast as the fruit is picked, as no method of cultivation which I am aware of will prevent their being infested with red spider.

Ply the syringe vigorously on the fruit trees when the Strawberry pots are removed, as very shortly the earliest Peaches will be taking the second swelling, and as the fruit shows signs of ripening syringing must be discontinued, otherwise the flavour will not be good. The first Peaches to ripen are Early Beatrice and Early Rivers; the fruit is small, but valuable from coming in three weeks before Early York. Early Grosse Mignonne is a very fine second early Peach, but the trees are not so robust as the Early York. The last to ripen are Lady Palmerston, Comet, and Salway, all yellow-fleshed. Desse Tardive, an excellent late sort, fruited last year for the first time; this is worthy of extensive cultivation. I proved many new sorts last year, but owing to the exceptional season it was not possible to report on them.

The Nectarine season does not extend so long as that

of the Peach. Hunt's Tawny is the earliest, and the last to ripen are Victoria and Prince of Wales.

The best time to repot the trees, and still make sure of a crop in the following year, is as soon as the fruit is gathered. I reduce the ball of roots sufficiently to repot again in the same size of pot, by keeping the house close and syringing the trees, the foliage does not suffer, and in less than a week the young roots will be pushing into the fresh material. All the trees are either repotted or surface-dressed by the middle of October, and turned out of doors. The trees here have been treated in this way for many years, and are still healthy and fruitful.

I have been taken to task both by Mr. Rivers and Mr. Pearson for placing the trees out of doors. In the thirteenth volume of this Journal, page 329, Mr. J. R. Pearson says, referring to Peaches in pots—"If left out during winter I should not expect them to retain their buds, and if we had a cold winter I should expect some to be killed outright." He is quite mistaken; the trees do not drop any buds, and during the severest frost of the present severe winter not one tree was injured. Now, let us again turn to THE JOURNAL OF HORTICULTURE, vol. xvi., page 420, Mr. J. R. Pearson says, referring to his own orchard-house Peaches, "They are nearly a total failure." "Nearly all the fruit had fallen off," &c. Now, what was the reason of this? He tells us "that it was a total absence of sun when the trees were in bloom." My four rows of hot-water pipes came in useful just at that time, and I had a splendid crop. I showed thirteen varieties of Peaches and Nectarines at South Kensington; the first prize was awarded to the collection; also one dish of Royal George, which had the first prize, and was said to be the best-flavoured Peach in the room. At the same time I was gathering several dozens every day at home for my employer and his friends, and both Mr. Barron, of Chiswick, and Mr. Rivers's foreman, Mr. Perry, told me they were the finest orchard-house Peaches and Nectarines they had ever seen. It looks egotistical to write like this, but when you are called to order by such men as Mr. Rivers and Mr. Pearson, it is only right that you should state the result of the method of cultivation you advise others to practise.

My reason for removing the trees out of doors is that the entire house may be devoted to Chrysanthemums, and I advise all who possess an orchard house to fill it with them in the autumn. Some of the Chrysanthemums are grown for quality of flower; for this purpose two or three plants are potted in a 10 or 12-inch pot, they are trained to a single stem, and only three flowers are allowed to each. These plants can be placed closely together to form a centre or background as may be desired; if the house is a lean-to they are arranged to form a background, and in a span-roofed house they are placed in the centre bed, with, in front of them, specimen plants of the large-flowering, Japanese, and Pompon varieties, which will furnish a succession of beautiful flowers until the end of the year, and now, by the aid of the Japanese and some other late-flowering sorts, the bloom is extended far into January.—J. DOUGLAS.

ORNAMENTAL VARIETIES OF OUR NATIVE GRASSES.

NOT till I had seen the beautiful Dactylis elegantissima at Kew did I think that the British Grasses could be made so useful for garden decoration. Since then I have turned my attention to them, and, to a certain extent, think I have been successful, having found eight or nine varieties of Grasses with variegated foliage. The first variegated Grass I ever found was in Kent—a wee seedling plant, not an inch in height, of Holcus lanatus, Timothy Grass. The same season I found Alopecurus pratensis, Meadow Fox-tail Grass, in a meadow. These were both distributed by one of our most enterprising nurserymen.

I have since found Phleum pratense albo-marginatum, which was sent out by the same firm. I have now Phleum pratense aureo-variegatum, a fine Grass; a Poa, an Agrostis, Triticum repens, Lolium perenne, a new Dactylis glomerata, and several others that have not yet flowered. One in particular is a wood Grass, with a remarkably bold snow-white variegation.

I find that most of our British Grasses may be found in a variegated state by looking carefully over them where they abound, chiefly in sandy soils. My experience proves that they are only found in very small portions, being mostly sports.

My Dactylis glomerata is a curious plant, that never flowers, a stronger variety than the usual variegated variety. I was curious to know the reason of its not flowering, and find, after careful examination, the presence of a parasitic fungus, which not only prevents its flowering, but, I think, must be the cause of its variegation also. During the summer months this Grass regains its green condition till, during the winter, the spores of the fungus become again active.

I have raised thousands of seedling plants from variegated Grasses, but they all come up green, with the exception of Lolium perenne, and not more than one per cent. of this. Some of these Grasses make a nice variety in the mixed herbaceous border, others are good for edgings, and it has been suggested that the dwarfer-growing kinds might be planted for making simple figures on lawns, to be mown as usual—for instance, Poa trivialis argentea.

In a future note I shall say something about our English wild Geraniums, thinking them proper subjects to come under the hands of the florist, and I hope that others besides myself will give a helping hand towards introducing these native wayside beauties into our gardens, for there is no knowing what may be obtained by a thorough investigation of these humble members of the vegetable world.—W. E., *Gardener, Cromwell House.*

THE ROYAL HORTICULTURAL SOCIETY.

ANNUAL GENERAL MEETING.

FEBRUARY 14TH.

THE Annual General Meeting of the Royal Horticultural Society was held on Tuesday afternoon in the Council-room of the Society, South Kensington. The chair was taken by His Serene Highness Prince Teck, in the absence of the President, the Duke of Buccleuch.

The Scrutineers appointed for the ballot were Dr. Masters and W. Beattie Booth, Esq. On the Meeting proceeding to ballot for members of Council, Office-bearers, and Expenses Committeemen for the ensuing year,

HIS SERENE HIGHNESS said:—Ladies and Gentlemen, the work which those members of Council and office-bearers undertook last year, and the manner in which they performed their task, is so fully set forth in the Report which will be read to you, that I will not intrude upon your time by referring to the subject. I cannot, however, refrain from expressing my gratification at presiding for the first time at one of your meetings, especially when I can see that the future of the Society will be undoubtedly bright [applause]. Your finances are increasing, and there has been, and is, a continuous progress in that work which is the special mission of the Society. This year, besides, brings you into one of those international contests which lead, not to the destruction of the precious life of man, but to the nurture and protection of that life which is bestowed upon fruits and flowers for the sustenance, the delight, and the enjoyment of all [cheers]. I will now call upon the Assistant Secretary to read the Report, and in the meantime I will ask you to fill up the vacancies for the year.

Mr. RICHARDS, the Assistant Secretary, was about to read the Report, which will be found appended, when

Mr. S. H. GODSON remarked, that one of the gentlemen to be elected on the Expenses Committee was not now on the Council. It was irregular, he thought, to have the ballot for the Council made before that for the Expenses Committee.

Lord HENRY LENNOX.—It is only a matter of form which can be explained in a few minutes.

Mr. RICHARDS then read the Report.

Colonel CHALLONER said it was not with a view to find fault that he rose, because he considered that on the whole the Report was satisfactory, but he did so because they really knew nothing about the finances of the Royal Horticultural Society. They ought to know a little more about them. Of course upon any finance question he should address himself more particularly to those gentlemen who had charge of the finance department; and he ventured to put this question to them—Whether the balance of 1869 was £1331; that was a balance against them, whilst at the present moment they had nearly the same amount of liability? And he should also ask this question, "Does the account from January to December include all the ordinary expenditure of the Society?

Colonel SCOTT, Secretary, said the account showed the absolute expenditure during the year. At the foot of the account the item of £1592 for liabilities on current account would be seen. That showed the liabilities at the present moment.

Colonel CHALLONER observed that he should have been glad if he had had a more satisfactory answer when he asked the same question two or three years ago. He should like to see the finances of the Society make the same appearance as their banker's book—assets on one side, and so much liability on the other. He certainly did not wish to have what he would not call "cooked" accounts.

Colonel SCOTT.—But the account, sir, shows everything fully as far as any account can show it.

Colonel CHALLONER.—Am I to understand that the expenses of the Royal Horticultural Society, including those of Chiswick garden, amounted to £12,189?

Colonel SCOTT.—That is quite correct.

Colonel CHALLONER.—I have had a seat at the Council for many years, and having taken a great interest in the finances, I like to understand exactly in what position we are.

Colonel SCOTT.—As a matter of fact, comparing the state of the Society now with its state last year, we are close upon £1000 better [hear]. We have paid off a large amount of our liabilities. The account shows the amount of liabilities paid off, the amount of our present liabilities, and what our expenditure was.

Colonel CHALLONER. — Would there be any objection to have the balance sheet made out a little plainer?

Colonel SCOTT replied, that they would be very glad to do so if the way were pointed out.

Colonel CHALLONER said he felt assured the Council would carry out the wishes of the Fellows in the best and most economic way. He begged to move the adoption of the Report [hear, hear.]

Mr. G. F. BLENKINS seconded the motion, and congratulated the Society upon having achieved so much success in the past year. He trusted the International Exhibitions when established would prove a permanent benefit to the Society, bring to them an increase of members, and an increase of funds.

Mr. BATEMAN rose to assure his friends on the platform and in the room that in addressing the few remarks to them he was about to make, he was influenced by no hostile spirit. He unfortunately dissented from the congratulation offered by his friend, considering the bargain they had made and the terms they had received from Her Majesty's Commissioners of 1851. He was much afraid when people came to understand all these things they would scarcely think them a subject for congratulation. He felt certain that the Duke of Devonshire had acted loyally and honestly by the Society, and that the Council of the latter had done their very best to make the most advantageous terms they could with the Commissioners. But, let them just go back some fifteen or sixteen years when the bargain was made whence these terms came, which might have appeared comparatively easy at that time, because the day of reckoning was to a certain extent far off. He need scarcely inform the Fellows of the Society that the gardens in the midst of which they then were owed their origin to a brilliant idea springing from the fertile mind of the late Prince Consort, an idea which from the day of its conception had been undergoing expansion and extension. The late Prince Consort conceived the admirable idea of associating together all the arts and all the sciences in a sort of happy family at South Kensington, and in order to carry out that idea a large amount of money had been expended. A bargain was struck, and the expenses of these magnificent gardens were to be defrayed jointly by the Royal Horticultural Society and Her Majesty's Commissioners. Although they were to be defrayed jointly they were not to be defrayed equally, but partly by the donations of life Fellows, and partly by loan. Her Majesty's Commissioners were profuse in their offers; they were not to be exceeded in their generosity and the profusion of their gifts by a royal dispenser of good things at the table of a monarch [laughter]. Well, when money was borrowed interest generally had to be paid, but this was precisely what the Royal Horticultural Society had never been in a position to do. The Society had never been able to pay the interest, and therefore they were now at the mercy of Her Majesty's Commissioners, who had it in their power to impose upon the Society if they pleased terms which would be hard and harsh—just such terms as the Prussian victors seemed anxious to impose upon the beautiful and beleaguered city of Paris. Now what these terms were he wanted to make the Society understand, and he would endeavour to do that by referring to what the Society had gained and lost. He should first take what they had lost. They had lost three admissions to their own gardens, and they would have no power of admission to their own premises during the greater portion of the year. It was true the Report spoke of the gates of the gardens being thrown open to the large and promiscuous company which would crowd the exhibition. When they came to remember that at one end of the gardens there would be a number of people engaged in convivial hilarity, and at the other end countless articles of machinery at work, and somewhere about the centre the band of the Middlesex Volunteers in full play as well, the less they said about the whole thing the better [laughter]. Indeed, as he had read somewhere, the state of things would

> "Rend their ears asunder
> With guns and blunderbusses, swords and thunder."

—[renewed laughter]. At all events they would not find themselves, as they now were, in quiet seclusion, because, even supposing the Commissioners were so good as to refrain from allowing all promiscuous visitors to the exhibition to come into the gardens, still the season ticket-holders would have that privilege, and hence the privacy which the members of the Society would enjoy in their gardens would not be so great as that which might be had in any one of the principal squares in London. Now, having reviewed what they had lost, let them see what they had gained. In the first place they gained a view of that noble hall, which he would say—whether they looked at the grandeur of its proportions, the dignity or severity of its lines, or its perfect adaptation to the object for which it was intended—was a marvel of architectural skill, which reflected the utmost credit on his excellent friend, who was on the platform at that moment [hear, hear]. Much might, no doubt, he said about the appendages that were left, but the less said about them now the better; something might come out of them by-and-by. But then they were told no one was to be admitted into the gardens or exhibitions without a capitation toll of a penny; and as some 500,000 or 600,000 persons might probably come to the gardens and exhibitions, that number of pence would barely suffice to pay the interest due to the Commissioners on the loan. For his own part he must say he did not feel very grateful for what the Commissioners had done for the Society. Excluded during the better six months of the year from all enjoyment of the upper arcade, they would be partly excluded from the lower one during the winter months, and at a time when all the Fellows would be out of town they would have the privilege of visiting what was left of the exhibition. The grandest concession to the Society, however, was in the matter of tickets. It might be supposed that tickets would be offered to the Fellows of the Society for exhibitions which were held almost entirely within their own demesne; but no, they were not to have the tickets for nothing, but at a guinea less than other people. The public would pay three guineas, but the Fellows of the Society should understand at once that they could not have the privilege of walking in their own arcades without paying two guineas for that privilege. It did not always suit a person to pay two guineas. It was not everybody who had two guineas to expend, nor was everyone who had two guineas willing to expend them. They would find by looking at the Great Exhibition that by far the greater number of the well-to-do people did not spend anything like two guineas to go to the exhibition, and he thought it would be very hard to have to pay two guineas now to see a very inferior exhibition. He thought these terms were exceedingly hard. Let them suppose for one moment that any person was in the habit of supplying them with milk or cream, that he withheld the supply, and when they complained he said, "Oh, you can have three gallons of water at the cost of two" [laughter]. That was pretty much the way in which the members of the Royal Horticultural Society would be treated. He made these remarks in order that they might find an echo in the breasts of some of the members, and probably reach the stony hearts of the Commissioners [hear, hear].

Mr. CLUTTON said the interest which the Society had to pay was originally fixed at 5 per cent. It was then reduced to 4 per cent., in which the bondholders acquiesced. It was quite true if they had profits they would be bound to pay rent to the Commissioners, but they had not made any profits, and, therefore, they did not pay any rent. With respect to the gardens, he might say that the Society found the total funds for making them, and all the buildings round the gardens and the arcades were erected by the Commissioners of 1851. He had had something to do with the arrangement for admission made with the Commissioners, and he could tell Mr. Bateman he was under a misapprehension if he thought the reduction was a part of the arrangement. If was simply an offer of the Commissioners of 1851, and he thought it was very liberal to give the Society the use of two arcades, one on the east and the other on the west side. It had been originally intended by the Commissioners to make a conservatory on the top of the roof. That was objected to on the part of the Council, and the Commissioners gave way, although it was part of the original agreement that the Society should give up that part of the building. He thought he ought to explain these questions in which money was concerned.

Mr. GODSON differed from the last speaker as to accounts. If he looked at the accounts he would find that money had been paid, but not to a very great amount. By paying a certain sum every five years they saved the privilege of their gardens; and if the Council did not pay their portion it was their fault, and not the fault of the Society. He was quite pleased to hear some of the remarks made by Col. Challoner, who had never come out in a similar way before. Now, first of all, he (Mr. Godson), was sorry he could not join in the congratulation respecting the Report. They all knew very well that in the minutes of last meeting it was stated they would give up Chiswick. If that were so, why had it not been done? With respect to walls being erected at Chiswick, he had suggested to the Council that they should have them entirely to themselves, so as to be able to shut out nuisances. One great drawback to Chiswick was the Militia barracks. Referring to Mr. Bateman's speech, Mr. Godson said that with respect to that "hideous building" Mr. Bateman had spoken of, he had heard His Royal Highness the Prince Consort point out a very different idea. There could, he thought, be no objection to tendering the thanks of the Society to His Grace the Duke of Devonshire. No doubt Chiswick garden would have been a great resort had it been properly managed. He thought, considering that the Council did not state their terms with the Duke of Devonshire, it would be more prudent of them to put down in an appendix what the terms were, and then they should all know what they were going to do.

Mr. CLUTTON remarked that at the Exhibition of 1861 they were enabled to pay a sum of £2000 as rent.

Lord HENRY LENNOX said he would answer a very few of the objections which had been raised that day. He thought it was a matter of great congratulation for the Council to find that even in the hands of so able a man as his friend Mr. Bateman, the bill of indictment which he brought against the Royal Horticultural Society was so small a one. Mr. Bateman, who no doubt would have spoken differently had he been among the Council on the platform, said they could have got better terms from the Commissioners. Well, they all wanted to get the best terms they possibly could, but Mr. Bateman was a member of the Council when the arrangement was entered into with the Commissioners. Therefore in these days, when so much is said of full and

official responsibility in public matters, he should be glad to see Mr. Bateman re-elected that day a member of the Council, to share with the rest of the members the responsibility of the agreement entered into with the Commissioners of 1851, which he as a good Fellow of the Royal Horticultural Society would wish to see improved or at an end. Mr. Bateman said, and truly said, he greatly regretted the use of the northern arcades. When Mr. Bateman was a member of Council it was true the Commissioners did debar the Fellows from the use of the northern arcades; but since the amended agreement had been entered into the Fellows had returned to them, and the Commissioners had put up a roof or covered way, which had just been formed and would be kept up until the exhibition was at an end. His friend Mr. Godson, with whom he had the privilege of crossing swords on a former occasion, gave great and full credit to Mr. Bateman for his speech, which was quite different from what he was in the habit of hearing from him. He (Lord H. Lennox) quite agreed with Mr. Godson as to the brilliancy of Mr. Bateman's speech, but the chief brilliancy in it was that opinion given, when the truth was out, that he was the last man who would find fault with the Council—when he fully admitted the difficulties they had to contend with, and cheerfully acknowledged how well they had surmounted them [hear, hear]. That was the fact of Mr. Bateman's speech which the Council accepted cheerfully, and for which they tendered to him their thanks; and he (Lord H. Lennox) hoped that when Mr. Bateman rejoined the Council he would be able to say to the Fellows, "We have met here to-day. Last day I was in the position of an elector, now I am in that of a minister, and I will give to you an account of my stewardship" [hear and laughter]. Now, his friend Mr. Bateman said persons had told him that the visitors to the gardens of the exhibition would amount to some five hundred thousand.

Mr. Bateman.—From five to seven hundred thousand.

Lord H. Lennox.—Well, from five hundred thousand to seven hundred thousand. It was highly probable that of those who visited the exhibition many circumstances must tend to diminish or increase the number; and there was nothing about which doctors differed so much as to what numbers would probably come, but he and his friends were in a position to say—from the information and opinion of those to whom the fullest credit may be attached in a matter of this kind—that the number of persons who would visit the exhibition—now that they could breathe again at the end of the fearful struggle abroad—would run from two to eight millions [hear, hear]. In that case, if the numbers only reached the lower figure, the arrangement made with Her Majesty's Commissioners would very soon repay the Fellows of the Society. His friend Colonel Challoner wished to see the balance sheet plainer. All he could say on the part of the finance officers was that they should be only too grateful if Colonel Challoner put himself in communication with them, and suggested any means by which they could simplify the accounts. No doubt the experience of Colonel Challoner would be very useful to them. Mr. Godson also said, that grateful as he was to the Duke of Devonshire, he wished the Council had told the Fellows how far the Society had been benefited by the garden at Chiswick. But it should be borne in mind that the Council say in the Report: "The Annual General Meeting having left the question to the decision of the Council, they proceeded to make inquiries, but whilst engaged upon them his Grace the Duke of Devonshire, in a most liberal spirit, expressed his readiness, if the Society chose to remain at Chiswick, to accede to an arrangement for the renunciation of the lease of a portion of the garden; and accordingly a new agreement was entered into with His Grace, by which the garden is reduced from thirty-two acres to less than twelve, and the rent has sustained a corresponding reduction." That was the answer to Mr. Godson; the Duke of Devonshire had allowed them to reduce their garden from thirty-two acres to less than twelve, and the rent had sustained a corresponding reduction. And it was after that sentence that the following, which probably drew out Mr. Godson's observation, came:—"The Council are of opinion that the thanks of the Society are due to the Duke for the liberality with which he has treated them, both in respect of rent and the terms on which the renewed lease is granted. These terms leave to the Society the option of relinquishing Chiswick whenever they shall judge it conducive to the success of its operations to seek another garden. They therefore recommend to the meeting to record a vote of thanks to His Grace." He (Lord H. Lennox) was willing to answer any further question that might be put to him before he went away. The presence in the chair of his illustrious friend, Prince Teck, was most encouraging for the Society [applause]. No one knew better than Mr. Bateman the difficulties the Society had had to encounter for a long time. He thought the Report which had been submitted to the meeting was a proof that the Society was steadily—slowly and surely—assuming the place which was intended for it by the illustrious Prince Consort [cheers].

Mr. Godson wished to know, with respect to the agreement entered into as to Chiswick garden, what was the term of years given, because the Society had spent £20,000 or £30,000 on the place. How much of that, he should like to know, was preserved to the Society?

Lord H. Lennox.—Twenty-one years, and to be renewed at will.

Mr. Godson.—At the option of the Council and Fellows?

Lord H. Lennox.—Yes.

Mr. Bateman said with regard to a remark of his noble friend (Lord H. Lennox), that he should have probably spoken differently had he been on the platform among the members of the Council, he would only say his noble friend was aware, as others were, that whenever any matter was brought before the Council, he (Mr. Bateman) never departed from what he considered the right course [hear].

Lord H. Lennox said he had spoken from his parliamentary experience, which had shown him how much easier it was to speak when in opposition than when sitting at the Treasury side of the House [laughter].

The resolution for the adoption of the Report was then put and carried.

The results of the ballot were then declared; James Bateman, Esq., F.R.S., John Kelk, Esq., and E. J. Lowe, Esq., F.R.S., having been elected members of the Council in the room of the vacating members—Andrew Murray, Esq., F.L.S., Sigismund Rücker, Esq., F.L.S., and Dr. Thomson, F.R.S. The officers were also appointed as follows—President, His Grace the Duke of Buccleuch, K.G.; Treasurer, John Clutton, Esq.; Secretary, Lieut.-Col. Scott, R.E.; Expenses Committeemen, John Clutton, Esq., W. Wilson Saunders, Esq., F.R.S., and Sigismund Rücker, Esq., F.L.S.; Auditors, James Nicholson, Esq., John Gibson, Esq., and Robert Hudson, Esq., F.R.S.

The Report of the Auditors having been read,

Lord H. Lennox said it had been forgotten to return thanks to Col. Scott, who was the excellent Secretary of the Society, and worked without any remuneration. He therefore begged to move a vote of thanks to Col. Scott [hear, hear].

Mr. Bateman seconded the motion, which was carried.

Mr. Godson ventured to tender His Serene Highness the heartfelt thanks of the meeting for coming there and presiding on that occasion. He assured His Serene Highness that the Society need not look to the future with any apprehension, but, on the contrary, to great success, if he gave as patient attention and hearing at the Council as he had that day in presiding over the meeting [applause]. He begged to propose that the thanks of the meeting be given to His Serene Highness.

Colonel Challoner in seconding the motion, said it was a great advantage to have a member of the Royal Family amongst them, and they ought all to be proud at any member of that family taking the chair at their meeting [hear hear].

The motion having been carried by acclamation,

His Serene Highness said—In the unavoidable absence of your President, I was asked to perform the duties of Chairman, which any one, indeed, could perform better than myself. I beg to express my satisfaction at being associated with this Society, for I take a real interest in horticulture, and to thank you for your kindness [applause].

The proceedings were then brought to a close.

Report of the Council to the Annual General Meeting.

1. The Council have the satisfaction of announcing to the Fellows that a considerable improvement has been effected in the financial position of the Society since the last Annual General Meeting. They can also speak with satisfaction of the horticultural work of the past year and of the promise of the present one. They have again to report an increase in the number of Fellows; the number now on the books is 3376, being an increase of twenty-five since the last annual Report. The number of resignations has been unusually small during the past year, which is another hopeful sign of the increasing popularity of the Society.

2. The actual amount of subscriptions received is about the same as in 1868 and 1869. In the former year it was £7113; in 1869, £7193; and in 1870, £7177. That the receipts have not kept pace with the increase of Fellows is due to the fact that the Fellows have not so largely availed themselves of their privilege of obtaining transferable tickets as in former years. It is to be hoped, therefore, that the full value of the increased number of Fellows has not yet been felt, and that a return of the commercial prosperity of the country will bring with it a corresponding desire to the Fellows to obtain for their friends the advantages which the transferable ticket system confers.

3. The receipts from exhibitions during the past year were higher than in 1868 or 1869, and the Council have the pleasure of reporting that, notwithstanding the greatly increased number of shows, the exhibitions of the Society may again be said to be self-supporting. After a trial of two years the Council see no room for improvement in their established arrangements, excepting in matters of detail. These arrangements appear to be satisfactory both to the Fellows and to the exhibitors, and since they are also financially successful, and are adapted to the exhibition of the progress of horticulture throughout all the seasons of the year, it may be safely assumed that they are more conducive to the advancement of the objects of the Society than those which they have supplanted. The exhibitions of the last year, regarded as a whole, have never been surpassed in usefulness and brilliancy.

4. The country show at Oxford was the least successful, from a financial point of view, of those hitherto yet held. The Council are, however, not discouraged by the solitary instance of a slight loss on these valuable endeavours to increase the Society's usefulness and popularity. This year's Show is to be at Nottingham, and if any opinion can be formed from the interest there felt in the visit of the Horticultural Society, the Nottingham Show will mark a new step in the career of usefulness on which the Society entered when it undertook the sys-

tem of holding annual country shows. This, too, is the first instance in which the Society, accepting the invitation of a locality, has ventured to leave the support which the presence of the Royal Agricultural Society was supposed to give, and to trust to its own efforts and attractions for securing a sufficient number of visitors to render the exhibition self-supporting. The Council are happy to report that the zeal of the horticulturists of Nottingham, and that strong love of flower-culture which has rendered this city so celebrated, has already raised the special prize fund to no less a sum than £500.

5. The bequest of £2000 left to the Society by the late Mr. Alfred Davis has been invested in Consols. One of the conditions of the gift was that the interest of the money only should be applied to the uses of the Society. In accordance with this condition the Council have determined to apply the first proceeds from the interest of the bequest to the purchase of a challenge cup, to be called the Davis Challenge Cup, to be won for a certain number of years as a distinction for successful culture. The terms of competition will be published shortly.

6. The Council for some years past have felt serious concern at the gradually increasing burden which has been thrown upon the funds of the Society for rates and taxes. The charge is made upon an arbitrary assessment by the parish, and not in reference to the actual returns as a garden. An intention of still further increasing the rates last year was announced to the Society, but was resisted, and the amount remains unaltered.

7. The Scientific, Fruit and Floral Committees continue to do good service to horticulture, and that of the most valuable kind. The Council much regret that the accounts published of their proceedings at a very serious cost to the Society seem to be little appreciated by the great body of the Fellows. This is doubtless in some measure due to the fact that their contents are necessarily anticipated by the horticultural journals; but whatever the cause, the Council do not think that they would be justified in entering upon additional expenditure, in order to secure a more rapid publication of information, which can readily be obtained at a trifling cost by those who watch the proceedings of the Committees with interest. The publications of the Society prove to be chiefly valuable for communication and exchange with Societies and individuals abroad. The Council fear that, having regard to the interests of the large majority of the Fellows and the limited means of the Society, they have not yet found the best mode of employing the funds which can be devoted to the publication of its proceedings. This subject will occupy their earnest attention during the present year.

8. The collection of economic entomology continues to make progress, and the thanks of the Society are due to the Fellows and their friends, who from time to time send contributions. One of the latter (who desires to be anonymous), has offered a sum of money in prizes for the best collection of entomological objects. The nature and arrangement of the objects to be submitted in competition are to be defined by the Council, and they now have this matter under their consideration. Mr. Andrew Murray has also undertaken to give six lectures during the coming season on economic and forest entomology. Due notice will be given both of the dates of these lectures and of the terms on which the prizes are offered.

9. The most important question dealt with in the Report of the Council to the last Annual General Meeting, was that of the Chiswick Garden. In this case also the increase of rates and taxes pressed very heavily, and these coupled with a large rental and the working expenses of keeping up a garden far more extensive than corresponded with the present requirements of the Society, had, indeed, become so heavy as seriously to cripple its resources. The Council, therefore, distasteful as they knew such a step would be to many of the Fellows whose wishes and opinions were entitled to great weight, concluded, after much consideration, that the wisest plan would be to endeavour to obtain a small working garden in a purer atmosphere than that of Chiswick, at some distance from London. The Annual General Meeting having left the question to the decision of the Council, they proceeded to make inquiries, but whilst engaged upon them His Grace the Duke of Devonshire, in a most liberal spirit, expressed his readiness, if the Society chose to remain at Chiswick, to accede to an arrangement for the renunciation of the lease of a portion of the garden; and accordingly a new agreement was entered into with His Grace, by which the garden is reduced from thirty-two acres to less than twelve, and the rent has sustained a corresponding reduction. The Council are of opinion that the thanks of the Society are due to the Duke for the liberality with which he has treated them, both in respect of rent and the terms on which the renewed lease is granted. These terms leave to the Society the option of relinquishing Chiswick whenever they shall judge it conducive to the success of its operations to seek another garden. They, therefore, recommend to the meeting to record a vote of thanks to His Grace.

10. An immediate consequence of the reduction of the space under cultivation at Chiswick has been a reconsideration of the principle on which the collections of fruit trees should be maintained. The original idea was to keep up a collection of all the kinds of fruit trees admitting of cultivation in the English climate, and it is believed that at one time it was nearly, if not quite, a perfect one. Of late years, however, the increase of varieties has been so rapid, especially on the Continent, that it has for some time past ceased to have any pretensions to completeness, and a very large proportion consisted of inferior kinds rarely or never cultivated. The advisability of keeping worthless kinds has been often questioned, and the moment the collection ceased to have pretensions to completeness, the chief argument in favour of preserving condemned kinds vanished. The Council believe that their action in having weeded out, under the advice of the Horticultural Directors, all those varieties which were unworthy of cultivation, will meet with the general approval of cultivators of the present day. The preservation of the best kinds has been effected, partly by transplanting and partly by grafting, with the success which usually attends the skill of the Superintendent, Mr. Barron. Similar success has attended the removal of the hardy perennials to the part of the garden which has been retained. Some new borders flanking the great conservatory are devoted to them, and new varieties are solicited from the Fellows. The extensive collection of bedding Pelargoniums has also been preserved.

11. In accordance with arrangements which have been contemplated since Mr. Eyles has, with a degree of success highly satisfactory to him, entered upon the profession of a practising landscape gardener, that officer will this year cease to be the Superintendent of the Kensington Garden, but he will still remain with the Society as the Superintendent of Exhibitions, a duty which is quite compatible with the exercise of the profession he has engaged in. He will also remain as a resident on the grounds of the Society, and exercise a general supervision over them in the absence of Mr. Barron, who will continue to reside at Chiswick, and undertake the superintendence of both gardens.

12. The Council cannot omit from their Report the expression of their expectation that the Annual International Exhibition, to be opened on 1st May next, under the direction of Her Majesty' Exhibition Commissioners, will tend greatly to the progress of the Society's operations. The unfortunate circumstances of the French people at the present moment must necessarily interfere materially with the horticultural competition, which might otherwise have been expected from that nation, but both Holland and Belgium intend to do their best to contest the prize for successful culture with the British nation, notwithstanding the disadvantages under which they must labour from the difficulties of transit to this country.

13. It is incumbent, also, on the Council again to draw attention to the extent to which the Society's future welfare is bound up with the success of the objects which Her Majesty's Commissioners are endeavouring in so liberal a spirit to carry out, and to urge them to give to the Annual International Exhibitions their best support. A Society consisting of upwards of 3000 members, of whom the large majority hold a high position in the country, may do much to add to that large measure of success which may reasonably be expected from so important an attempt to add to the prosperity of the arts and industries of the nation. The Council have felt it right, believing that they were carrying out the wishes of the body they represent, to meet the Commissioners in every point in which it appeared that the proposed arrangements would conduce to the success of their great undertaking —an undertaking, of which the Society will share the benefits, being pecuniarily interested in the number of visitors to the Exhibition.

14. It is perhaps unnecessary to remind the Society that its Fellows, by the arrangements entered into with the Commissioners, have the privilege of obtaining season tickets for the Annual International Exhibitions at one guinea less for each ticket than the price charged to the public. These tickets, will admit both to the Fine Art and Industrial Galleries on each side of the gardens, and to the Daily Musical Performances in the Hall during the continuance of the Exhibition. The following modification in the terms of arrangement with the Commissioners respecting the use of the arcades being more favourable to the Society than the original propositions, the Council had no hesitation in concurring in it.

Office of H.M. Commissioners for the Exhibition of 1851,
5, *Upper Kensington Gore, London, W.*

Sir,—Referring to the terms of arrangement entered into between Her Majesty's Commissioners for the Exhibition of 1851 and the Royal Horticultural Society, for the use of the Society's Gardens by the visitors to the forthcoming Annual International Exhibitions, I am directed by Her Majesty's Commissioners to inform you, that during the progress of their preparations for those Exhibitions, the following modifications of the terms in question have suggested themselves to the Commissioners, who, thinking that if adopted they would prove beneficial alike to the Commissioners and to the Society, have directed me to communicate them to you for the consideration of your Council.

In Article 1 it was agreed that the Society should give to the Commissioners the use of the Northern Arcades, the Commissioners providing in lieu thereof, for the use of the Society, a covered communication on the roofs of those structures, between the Orchard House entrances and the Conservatory.

Her Majesty's Commissioners now propose that the Society should retain the North Arcades, thus preserving their present and more convenient means of access to the Conservatory, and should give to the Commissioners instead the exclusive use of the Eastern and Western Arcades, which would be enclosed, at the expense of the Commissioners, by a light trellis-work fence. The covered communication over the North Arcades, which has been erected by the Commissioners in compliance with Article 1, would then be used by them as a means of access to the Royal Albert Hall, and to the wings of the Exhibition Galleries, the communication being completed by means of a passage along the back part of the Gallery of the Conservatory.

As the Commissioners have acquired from Her Majesty's Government the temporary use of the South Arcades, they also propose, as a part of this new arrangement, to construct a passage beneath the Council-room of the Society, and thus to complete the circuit of the Gardens.

With reference to Article 8 of the terms of arrangement, securing to

the Fellows of the Society the exclusive use of such portions of the annexes as are not required by Her Majesty's Commissioners, I am directed to inform you that the development of the Exhibition will necessitate the occupation of the whole, or nearly the whole, of the annexes, and that, consequently, the Commissioners would be unable to leave to the Fellows, to any substantial extent, the privilege contemplated by the article. On the other hand, Her Majesty's Commissioners propose (but, without binding themselves to a course which might prove very detrimental to the success of the Exhibitions) to make the experiment of curtailing that free use of the Gardens by visitors to the Exhibition, which was provided for in the original arrangement, by making an extra charge for admission thereto. The effect of this measure would obviously be to secure to the Fellows of the Society a much greater degree of the quiet which they have hitherto enjoyed than they would retain if the Gardens were to be thrown open to every visitor to the Exhibition.

I have the honour to be, Sir,
Your obedient servant,
HENRY Y. D. SCOTT, Lieut.-Colonel, R.E.
Secretary.

The Assistant Secretary of the
Royal Horticultural Society.

15. The Council desire, in conclusion, to record their satisfaction at the successful completion of the Royal Albert Hall, in which a large number of the Fellows of the Society are shareholders. They are informed that Her Majesty has announced her intention of opening it on the 29th March next.

EXTRACTS FROM THE REPORTS OF THE HORTICULTURAL DIRECTORS.

SCIENTIFIC COMMITTEE.—Numerous matters of greater or less interest have come before the Scientific Committee during the past year, which are recorded in the Society's journal. Amongst these the most prominent are Mr. Glaisher's observations on the meteorological records which have been carried on for so many years at Chiswick. It is a great satisfaction to the Society that the doubts as to their accuracy since 1860 have been quite cleared up, and a comparison of them with coteimporaneous observations at Greenwich has enabled him to attain many useful results which will be published in an appendix to the journal.

The experiments on the effect of different manures on the comparative development of a certain number of plants have been carried on very carefully at Chiswick, and the results which, notwithstanding the unfavourable season, have been of much interest, and are already published.

Mr. Anderson-Henry has sent some valuable observations on hybridisation, and Mr. Andrew Murray has lately read an interesting paper on that subject, as illustrated by the phenomenon of mimetic insects.

Amongst minor matters the occurrence of a manna-like substance on Peach leaves and twigs at Chiswick, but which really appeared to be more allied to stearine, deserves especial notice, as also Mr. Laxton's observations, accompanied by specimens, on the effect of crossing in Peas on the colour of the seed.

POMOLOGICAL DEPARTMENT.—In consequence of the contemplated changes that were decided upon at the beginning of last year, in the garden at Chiswick, it was considered impolitic to cultivate that portion of it which has hitherto been occupied as the orchard and kitchen garden, and consequently no experiments were last year undertaken in the open ground. But the great success that has attended the cultivation of the more tender kinds of fruits in the new orchard house has resulted in securing very copious notes on Peaches, Nectarines, and Apricots, which will serve in the preparation of future reports on these subjects. For some seasons past considerable attention has been given to the investigation of the numerous varieties of Figs, hitherto in a sad state of confusion as to nomenclature, and a correct knowledge of their merits and characteristics; and again this season great additions have been made to the observations already obtained.

The inside border of the great vinery (formerly the conservatory) has been entirely removed, as well as the Vines which it contained, and the house is now furnished entirely by Vines growing in the outside border, which has been considerably enlarged.

Notwithstanding the abandonment of the old orchard, the whole of the valuable collection of fruit trees has been preserved, only duplicates, and some varieties which had been proved essentially worthless, having been destroyed; yet some of these, which had acquired a symmetrical habit of growth, were successfully re-grafted with superior varieties, and will preserve their place in the collection. An entire rearrangement of the whole collection, both of Apples and Pears, has been made, and will occupy compartments on the new ground which has been broken up and laid out for the special purpose.

The crops of fruit have, during the past season, been generally abundant, with the exception of those on the Pyramid Cherries and Plums, which were almost a total failure.

By the new arrangements that are being made in the garden there will be ample space at command for carrying out all experimental operations which the Society can desire; and the more compact state of the garden will admit of a concentration of labour which could not formerly be obtained, and thereby conduce to greater ease and efficiency in the conducting of experiments and the preparation of reports.

As has been the case in former years, so in the past, the Fellows of the Society have largely availed themselves of their privilege of obtaining scions, cuttings, plants, and seeds from the garden; and nurserymen especially, who are Fellows, appear to estimate at the proper value the privilege of renewing and correcting their collections of fruit trees from the trees at Chiswick. During the past year 62,000 packets of seeds have been distributed; 2250 sorts of cuttings of fruit trees, including many collections of Figs, Vines, and Gooseberries.

FLORAL DEPARTMENT.—The floral department at Chiswick has rendered the Society good service during the past year. First, as regards supply. The number of plants distributed to the Fellows, by ballot or otherwise, has been 13,700, and the number of packets of flower seeds, 60,000; while the contribution to the garden at South Kensington, though less than usual as regards numbers, owing to the reduction of the bedding-out there, has extended to 28,144 plants.

Though it was found impracticable, under the circumstances in which the Superintendent was placed, to carry out the usual trials of new varieties of Bedding Pelargoniums, &c., yet a successful effort has been made to retain the extensive collection of sorts which had been got together, with the view to resume these useful critical comparisons as soon as practicable.

The collection of Hardy Perennials, which it is hoped may be further extended from year to year, has also been preserved, and removed from that part of the garden which has to be given up. Some new borders flanking the great conservatory have been devoted to them, and further contributions to the collection are solicited from any of the Fellows, or others, who take interest in herbaceous plants—a class which has latterly been far too much neglected.

The cultivation of stove plants—one of the least useful and most expensive branches of the floral department—was relinquished when the necessity for curtailment became evident, the houses being devoted to the growth of less tender plants for the conservatory at South Kensington.

Amongst the subjects provided for ballot during 1871, will be found some novel and extremely interesting fringed-flowered Petunias, both double and single; which have been raised at Chiswick. They are very handsome plants, and will form a pleasing variety amongst Petunias. Other novelties raised at Chiswick, and which will be distributed in the course of the season, are a fine new Dieffenbachia; Tacsonia speciosa, a handsome Passion-Flower; some of the golden-leaved Caladiums referred to last year; and variegated zonal Pelargonium Amy Richards, which is considered to be one of the best bedding varieties yet obtained.

Abundant facilities will be afforded in the new garden for carrying on the useful work of the floral department, it being intended to form beds for the experimental trials of flowers on a strip of ground between the Council-room and the conservatory—a situation which is in every way well adapted for the purpose.

FRUIT AND FLORAL MEETING, &c.

FEBRUARY 15TH.

THIS Meeting was one of the most successful the Society has ever held—successful in the diversity, the interest, and the beauty of the objects which it was the means of bringing together at a season when plant-life is only beginning to awaken from its winter's rest; successful in a still higher degree in the almost unprecedented attendance of visitors, so great that standing room in the afternoon was as much as they could obtain, and of that there was none to spare. The combined meetings and shows have evidently been a step in the right direction, and have aroused and kept alive an amount of horticultural interest, greater than the most sanguine ever expected.

FRUIT COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair. The Sub-Committee appointed at last meeting to report on the merits of the Galloway Pippin, reported that it was a cooking Apple of first-rate excellence, and a first-class certificate was accordingly awarded to it. Thomas Laxton, Esq., of Stamford, sent a seedling Apple, A, raised from Stamford Pippin fertilised by Golden Noble. It is medium-sized, roundish, and sometimes a little conical; the skin yellow; eye open, and stalk short; the flesh yellowish, firm, crisp, and juicy, with a nice perfume. It was commended. Another seedling, marked B, was smaller, flat, and also yellow, with a long stalk, firm, crisp flesh, and of good flavour. Mr. Laxton also sent six dishes of Apples in excellent preservation, to show the successful mode in which fruit may be kept in an underground wine-cellar, with no communication with the external air, and only a slight opening into another cellar, when the fruit will keep for a considerable time. The whole of the fruit sent had been kept packed singly, eye downwards, on deal shelves, covered with newspaper to prevent the wood flavouring the fruit.

Mr. E. J. Lowe, of Nottingham, sent a seedling Apple, raised from Bess Pool. It had a very strong resemblance to its parent in every respect, and the flesh was firm. It was not, however, considered superior to the older variety. Mr. Rivers, of Sawbridgeworth, sent fruit of Passe Crasanne Pear, grown by Mr. Tyler on a tree grafted on the Quince stock. The flavour was good, but not remarkable. Mr. Parsons, of Fairlawn, Acton Green, sent good specimens of Beurré Rance Pear, which were void of flavour. Mr. Tillery, of the Gardens, Welbeck Abbey, sent three dishes of Apples from a wire trellis, to show the fine colour they had attained during the past season. Cox's Orange was by far the best in flavour, being superior both to Ribston Pippin and Melon Apple, the latter being long past its season. Mr. Domenico Piccirillo, of Wigmore Street, sent dishes of Sweet Limes and Lemons, grown at Portici, to which a special certificate was awarded. Mr. Chilman, Somerley Gardens, Ringwood, sent fruit of Black Jamaica and Montserrat to ascertain if they are identical. A Sub-Committee was appointed to investigate the whole question of the nomenclature of Pine Apples, and to report at next meeting.

Mr. Gilbert, of Burghley Gardens, sent a collection of nine varieties of Potatoes, consisting of Coldstream Early, Jersey Blue, Prince of Regent, Pink-eyed Regent, King of Potatoes, Selected Lapstone, Myatt's Ashleaf, and Rivers' Ashleaf and Silver-skin. They were very fine samples, and received a special certificate.

Prizes were offered for the best three dishes of Dessert Apples and the best three dishes of Dessert Pears. Many fine dishes of both fruits were exhibited. The first prize for Apples was awarded to Mr. Garland, gardener to Sir T. Dyke Ackland, Bart., Killerton, for Cox's Orange Pippin, Cornish Gilliflower, and Ribston Pippin; the second prize went to Mr. A. Parsons, gardener to W. J. Blake, Esq., Danesbury. For Pears the first prize was also taken by Mr. Garland with Winter Nelis, Bergamotte Esperen, and Easter Beurré; Mr. Miles, gardener to Lord Carrington, Wycombe Abbey, being second with Beurré de Rance, Monarch, and Easter Beurré. The finest dish of the last-named variety was, however, shown by Mr. Sage, gardener to Earl Brownlow.

FLORAL COMMITTEE.—Mr. J. Fraser in the chair. Messrs. Rollisson and Sons, Tooting, sent a beautiful group, chiefly consisting of Orchids. Among these were a remarkably fine specimen of Cypripedium villosum with a score of fully-expanded flowers and buds, and a magnificent plant of the white and gold Cœlogyne cristata a yard across. In the same collection were Vanda tricolor insignis, very fine in colour; Odontoglossum pulchellum majus; Cypripedium insigne Maulei, a very fine variety; Odontoglossums; Dracæna Guilfoylei, and Lomaria gibba crispa. Davallia clavata, a very elegant new Fern also came from the same exhibitors.

Mr. Denning, gardener to Lord Londesborough, sent a superb group of Orchids, including a magnificent specimen of Cœlogyne cristata, blooming even more freely than Messrs. Rollisson's plant, and a remarkably fine specimen of Dendrochilum glumaceum; Odontoglossum Alexandræ, O. cariniferum, several fine varieties of Cattleya Trianæ, Lycaste Schilleriana, Pilumna fragrans, deliciously scented, and Trichopilia suavis were also represented by finely-bloomed plants. There was also a cut spike of Phalænopsis intermedia Porteana, the colours of which are very beautiful, especially these of the lip, which is magenta, shaded with orange at the base.

From the Society's garden came a fine collection of Orchids, consisting of Lycaste Skinneri, Oncidium Cavendishii, a lovely variety of Cattleya quadricolor, &c.

Mr. Williams likewise sent a group of Orchids containing a very fine specimen of Cypripedium villosum, Lælia superbiens, lovely; Vandas, Cattleyas, Odontoglossums, Cœlogyne media, Pleione humilis, &c. Mr. Williams also exhibited a collection of Palms, and a most effective miscellaneous collection, comprising hybrid Solanums, Hippeastrums, Aucuba luteo-carpa, the berries, however, having a reddish tinge, and various flowering plants, the gem of which was the lovely Tillandsia Lindeni, of which a figure and full description will be found in vol. xviii., page 359.

Messrs. Veitch, of Chelsea, contributed a splendid miscellaneous group, in which were several Lycastes, Dendrobium crassinode, a magnificent spike of Odonteglossum Alexandræ, Hyacinths in fine bloom, Aucubas in berry, and Hippeastrums. Messrs. Veitch also sent a very fine collection of Cyclamens, and one of Chinese Primulas of an excellent strain.

Messrs. Dobson & Sons, of Isleworth, likewise sent a collection of Chinese Primulas; and Mr. Tomkins, nurseryman, Birmingham, Princess Louise Chinese Primrose, with large white flowers tinged with blush. Mr. Kinghorn, Sheen Nursery, Richmond, exhibited a very fine specimen of the green-leaved Aucuba, covered with dense clusters of its brilliant berries.

From Mr. Ball, Chelsea, came a numerous collection in which were several Palms, a fine Encephalartos, Encephalartos Ghellinchii, Dracænas, Aucubas, and numerous Orchids. Gastronema flammea, with beautiful intense rosy crimson flowers, received a first-class certificate, and is a great acquisition.

Mr. Ware, Hale Farm Nurseries, Tottenham, sent a very interesting collection of spring-flowering plants, such as Cyclamen repandum, C. Atkinsi, Primula denticulata, Spiræa japonica, Iris reticulata, &c. Mr. Ware also exhibited a collection of succulent plants.

Messrs. Cutbush & Son, Highgate, exhibited a large and very effective miscellaneous collection, in which were a number of remarkably fine Hyacinths, Spiræa japonica, and Cytisuses, backed with Palms.

From Mr. W. Paul, Waltham Cross, came a group of eight fine specimen Camellias full of buds and bloom, and with dark glossy foliage betokening perfect health and vigour. Accompanying these were a number of smaller plants not in flower, and in front of all a row of Correa cardinalis about 1 foot high, and producing a profusion of their brilliant scarlet blooms, which offered a striking contrast to the green leafage behind. Mr. W. Paul also exhibited boxes of very fine cut blooms. Mr. Baxter, gardener to C. Keiser, Esq., of Broxbourne, also sent a box of fine cut blooms, and one of Kelvingtoniana, very large and fine. From Mr. Goddard, gardener to H. Little, Esq., Cambridge Park, Twickenham, came a fine collection of Cyclamens, and a similar collection of larger plants in fine bloom came from Mr. Day, Acton Green. Mr. W. Paul again exhibited his Primula, Waltham Bride, with very large pure white flowers. Mr. George, gardener to Miss Nicholson, Putney Heath, again sent his new Solanum, called Robustum aureum, with orange berries. E. J. Lowe, Esq., Highfield House, Nottingham, sent several seedling Ferns, among which were Polystichum angolare Moorei, a dwarf form raised from P. angulare acrocladon and depauperatum; also Scolopendrium vulgare proteoides, with a remarkable diversity of fronds, the plant being a viviparous one from a frond of S. v. pseudo-Wardii.

Mr. Green, gardener to W. Wilson Saunders, Esq., exhibited a new species of Agave from Africa, and A. Bessereriana amœna, of a glaucous hue, with dark-coloured very sharp spines.

Messrs. Veitch sent a collection of plants to compete for the prizes offered by Major Trevor Clarke, for the exhibitors obtaining the greatest number of marks for plants illustrating the phenomena of hybridisation. Messrs. Veitch's specimens consisted of Alocasia Sedeni, Nepenthes hybrida, N. hybrida maculata, Rhododendron Princess Royal, Goodyera Veitchii, Echeveria glauco-metallica, a fine specimen of Nepenthes Dominiana, and a Cypripedium.

Mr. Stevens, gardener to G. Simpson, Esq., Wray Park, Reigate, sent a basket of Lachenalia tricolor, which had an ornamental effect as a hanging basket. Messrs. Paul & Son sent Hippeastrum vittatum rubrum to show its utility as a hardy early bulb for forcing. At Cheshunt it is grown out of doors and merely protected with some leaves.

First-class certificates were awarded to Mr. Green for Agave Bessereriana amœna; to Mr. Tomkins for Primula Princess Louise; to Mr. Denning for Pilumna fragrans; and to Mr. Bull for Gastronema flammea.

Special certificates were awarded to the following—viz., to Mr. W. Paul for Camellias in pots, also for cut blooms; to Messrs. Rollisson for a group of plants; to Mr. Denning for a collection of Orchids; to Mr. Ware for Succulents and spring flowers; to Mr. Edmonds for Cyclamens; to Messrs. Cutbush for a miscellaneous group; to Mr. Denning for Dendrochilum glumaceum, also for Cœlogyne cristata and Pilumna fragrans; to Messrs. Veitch for twenty-four Primula sinensis and for Cyclamens; to Mr. Day for specimen Cyclamens; to Mr. Stevens for Lachenalia tricolor; to Mr. Bull for Orchids, also for his collection of Palms, &c.; to Mr. Goddard for Cyclamens; to Mr. Baxter for cut Camellias; to Mr. Williams for a group of plants, also for a collection of Orchids; to Messrs. Veitch for their miscellaneous group of plants; and to Mr. Kinghorn for his berried Aucuba. A special certificate was also given for the group from the Society's garden.

Prizes were offered for the best six Primulas. The first prize was awarded to Mr. G. Goddard, gardener to H. Little, Esq., Twickenham, who had finely-bloomed plants of white and crimson varieties. Mr. Edmonds, Hayes Nursery, was second, having two pretty little double varieties.

The first prize for the best three Dielytras was awarded to Mr. Bull for specimens by no means remarkable. No second prize was given.

Prizes were also offered for six Lycastes. Mr. Denning, gardener to Lord Londesborough, had the first prize for three remarkably fine specimens, and three of less size, Lycaste Skinneri being the only kind shown.

A letter from the Rev. Joshua Dix, the Chairman of the Committee, was read, tendering his resignation of that office in consequence of illness, but the Committee expressed a strong feeling against the acceptance of the rev. gentleman's resignation, and requested he would continue with them at least till the end of the year.

General Meeting.—J. Bateman, Esq., F.R.S., in the chair. Thirty-one new Fellows having been elected, and the Committee awards announced, the Rev. M. J. Berkeley, in remarking on the objects exhibited, particularly directed attention to Tillandsia Lindeni, which, he said, was most exquisite, and promised, in the case of Mr. Williams's plant, to produce a long succession of its azure flowers, a colour than which none probably was more wanted in our collections. Mr. Bull's Gastronema, at first thought to be a Vallota, was next referred to as being a brilliant Amaryllid, a true Gastronema, and entirely distinct from G. sanguineum. Scolopendrium vulgare proteoides, from Mr. Lowe, was then noticed as being a great curiosity, producing on one root Parsley-like, forked, and pinnated foliage, and on this a number of bulbils, by which it could be propagated. Mr. Bobinson had brought a beautiful golden Lichen from California, of which a specimen was before the meeting. It was the same as Borrera flavicans, which grows on trees in Devonshire and in Madeira. The tuberiform bodies which are found on the roots of Peas, Beans, and other Leguminosæ had recently occupied some attention, and they had by some persons been considered to be galls produced by insects, by others as being connected with the nutrition of the plant. Similar bodies had been noticed on Conifers and the Alder. At present nothing certain was known respecting their nature, but he had sown a quantity of Bean seed in order to endeavour to arrive at some satisfactory conclusion.

Mr. Bateman said he had never seen a richer gathering of Orchids than that exhibited, and expressed his gratification at seeing the nurserymen putting forth their strength. In connection with the beautiful Phalænopsis from Lord Londesborough, Mr. Bateman remarked that there was a prospect of new species of Phalænopsis and other Orchids from a Scotch gentleman in New Guinea. That vast island was the most perfect *terra incognita* he knew of, for, except that Wallace had given an account of his travels on its western side, he was aware of no other white man who had visited it. He had been authorised by the Society to secure the assistance of the gentleman referred to in collecting plants. Messrs. Veitch's Dendrobium heterocarpum was noticed on account of its delicious scent of Violets; also Pilumna fragrans from Lord Londesborough, and which should now be called Trichopilia fragrans. It, together with Cœlogyne cristata, some of the Cattleyas, and Odontoglossum Alexandræ were what he called bridal Orchids, from their colours being white and gold. After referring to some other Orchids exhibited, Mr. Bateman said the golden Lichen would be an admirable substitute for what was known as French Moss, so much used in dinner-table decoration, and which lately it had not been possible to obtain. He thought it would well repay anyone who would get the urchins in Devonshire to collect it, in order to send it to the London market.

Mr. William Paul then read a paper on the Camellia, which we shall publish next week.

Mr. Marshall said there appeared to be some misapprehensions with regard to the conditions of competition for the challenge cup [These were stated at page 49.], and again explained them. He further remarked that the challenge cup of the value of £50, to be given to anyone winning it three times had been withdrawn, and a cup, value £25, to be given yearly, was to be substituted.

Royal Horticultural Society's Prizes for Primroses.—We are requested to state that the competition for prizes offered for Primroses by the Royal Horticultural Society will take place on April 5th instead of on May 3rd.

ROYAL HORTICULTURAL SOCIETY'S PRIZE FOR HYACINTHS.

The prize for white Hyacinths was intended as a special premium for a definite purpose. What this was I will try to explain, by taking the case of an intending amateur purchaser of a few good Hyacinths for the ornament of his house or houses. The first thing he does is to consult his nurseryman's bulb catalogue, where he finds from twenty to forty sorts of each colour, single and double respectively. From these lists he has to make his choice on very inadequate data. Price is scarcely a criterion, for many of the finest sorts are comparatively cheap; often, too, the difference in quality between these and some higher-priced novelties is not very striking. Many varieties so nearly resemble each other, that none but a Dutch grower or other expert could distinguish them, much less the ordinary lady or gentleman amateur. By the proposed method of exhibition, a good number of varieties of one description of flower, as to colour, will be, as it were, paraded for inspection by the public, who may thus gain such a knowledge of the respective merits of varieties as could be obtained in no other way. The white form was selected as best suited for a trial of the merits of the system, to be followed by like premiums for other colours. Your correspondent would have no difficulty in purchasing two additional whites in the trade to make up his collection.

I hope the Rev. H. Dombrain, whose opinion in such matters is entitled to respect, will see that the premium in question was not a mere random or meaningless experiment.—C.

CIRCULAR FLOWER BEDS.

Of the various geometrical forms introduced into flower-garden designs there is none so useful as the circle; the ease with which it may be adapted to any position, its graceful outline, and the great scope which it affords for producing skilful combinations of colour, all tend to make it very desirable for this purpose. Seen in contrast with angular beds circles are quite certain to be viewed favourably; the soft outlines meeting the eye from every point of view convey an impression of grace and refinement such as the most skilful planting fails to impart to the stiff formality of an angle. Another advantage is, that a number of circles of the same size may be arranged in groups of three or more, or a large circle may be surrounded by a ring of smaller ones.

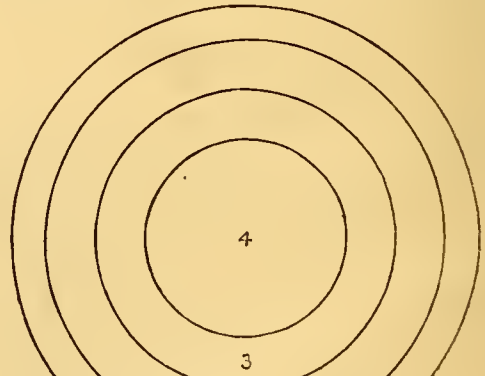

Fig. 1.

In planting such beds due regard must be paid to their size. Those measuring from 3 to 6 feet in diameter appear best when filled with one colour only, while in larger circles two or more colours may be introduced with an equally pleasing effect. In the latter case it is of much importance that the subdivisions should be so arranged as to be sufficiently clear of each other, in order to present the design to the eye free from all confusion. To do this it is best to mark the outline of any figure which

may be introduced into the circle with distinct-coloured, erect-growing, fine-foliaged plants, so that each compartment or division of the design may stand out clearly and distinctly, however intricate may be the pattern. There are a large number of figures suitable for such a purpose, a knowledge of geometry enabling one to introduce them in an almost endless variety; but I would always prefer simple forms rather than very intricate ones, not to avoid any difficulty of colouring, but because a design composed of a few simple lines is certain to produce the more pleasing effect.

By way of illustration I append four examples, each having two distinct arrangements of colour. All these designs are suitable for circles of from 10 to 20 feet in diameter.

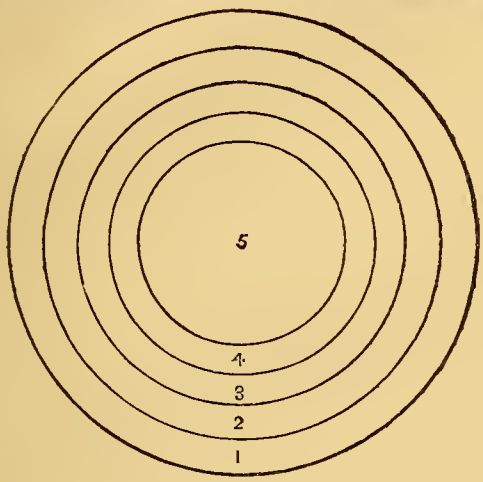

Fig. 2.

ARRANGEMENT OF COLOURS.

Or—

1. Santolina incana
2. Alternanthera amœna
3. Pelargonium Crystal Palace Gem
4. Lobelia Little Gem
5. Coleus Verschaffelti

I have thus combined a few choice bedding plants, but it should be remembered that the position of a bed and the nature of its surroundings must be known before any suitable arrangement of plants can be given for it. Take, for instance, a circle or number of circles situated on a broad, extensive lawn, or near a lofty mansion, or where there are large specimen shrubs, the planting of these beds should certainly be massive in character, even if the beds are 10 or 12 feet in diameter. One bed might be a mass of crimson with a broad band of yellow; the next might have three colours—white, pink, and purple; then we might have a grand mass of Golden Tricolor Pelargonium Lady Cullum surrounded by a broad band of Trentham Blue Lobelia; and so I would go on to the end with these alternating masses, just sufficiently varied to avoid monotony. Fancy a chain of such beds on a wide-spreading lawn, the beds surrounding yet well away from a fountain of an architectural design, and with fine masses of shrubs, or noble specimens of these, forming an enclosure or background, and you have a scene of rare loveliness—simple it may be in form, yet so graceful, rich, and dignified, that it might bear favourable comparison with the most complicated geometrical design. No objection could be taken to it on the score of heaviness, for the waters of the fountain would impart lightness and animation, and would also serve to agreeably break up or relieve the other-

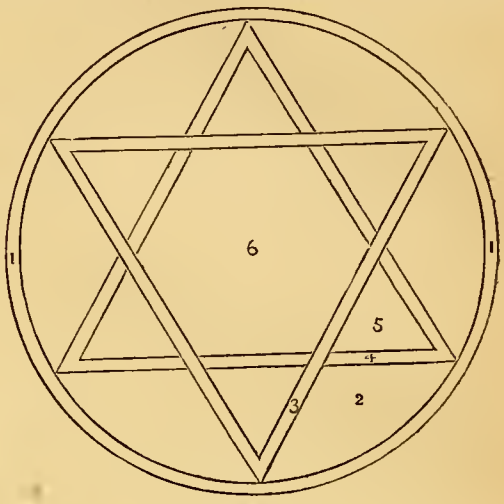

Fig. 3.

wise flat surface. It is in the few beds of small gardens or grounds that I would introduce a more mixed style of colouring

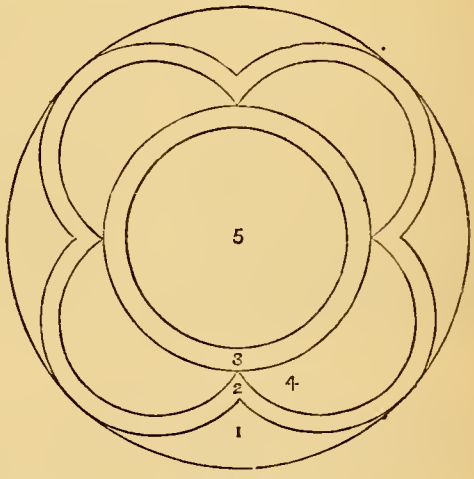

Fig. 4.

throughout, aiming to combine as much of interest and beauty as the space would admit of.—Edward Luckhurst.

WHAT IS A WEED?

At a meeting of our Mutual Instruction Club last Monday, the question was asked by one of our members, Is not any plant a weed that is growing where it is not required? This led to a dispute, and many were the answers as to What is a weed? Failing to reach to a unanimous answer, it was resolved to ask for your definition.—A. R.

[No plant in the estimation of the botanist is a weed, but with the gardener any herb that is not cultivated for its utility, beauty, or fragrance is a weed. Your member's definition is too wide. Mignonette sprung up among Cabbages would not deserve the epithet of a weed—it would only be a flower in the wrong place. Whilst writing we have had the following extract from the *Philadelphia Ledger* brought to our notice:—"It is stated that there are now no less than 214 weeds which have been introduced into the United States from foreign countries, and principally from England. As a proof of the rapidity with which useless plants are accidentally brought over the seas, it is said that in 1837 there were only 137 foreign weeds known in this country. As far back as 1672 a curious little volume,

called "New England's Rarities," gave a list of twenty-two plants which the author considered had sprung up since the English had kept cattle in New England. The author mentions the Plantain, which, he says, the Indians call the "Englishman's foot," as though produced by the tread of the white settlers. The common Yellow Toad Flax, it is stated, was originally introduced into the province of Pennsylvania as a garden flower by a Mr. Ranstead, a Welshman, residing in Philadelphia, from whom it has derived the name of Ranstead weed. In 1758 this weed had overrun the pastures in the inhabited part of Pennsylvania, and was the cause of bitter complaints from the agriculturists of that day. Chickweed, it is stated, was introduced in South Carolina as food for canary birds, and in ten years spread for upwards of fifty miles, and now occupies the outposts of civilisation. The Scotch Thistle is said to have been brought to America by a clergyman who carried with him a bed stuffed with Thistle down, in which some seed remained. Feathers being cheap in the new country were substituted for the down, which was soon emptied out, and the seed springing up filled the country with Thistles. Another account says some enthusiastic Scot introduced the Thistle as an emblem of his country, which soon made itself at home and became a nuisance." We do not know whether our American cousins will add to their Alabama claims a claim for compensation for the intrusion of weeds, but, if they do, we hope our Government will plead as a full set-off the introduction of that unconquerable American aquatic weed, Anacharis alsinastrum, which is filling our ponds, choking our reservoirs and hampering our water-wheels.—Eds.]

DEATH OF VINES UNEXPLAINED.

Six of my Vines are quite dead. There were thirteen in the house, all healthy flourishing canes last year, and seven are so still. They are side by side, and all treated exactly alike. They were all pruned as usual and dressed the same as in other years. From half to three-quarters of a pound of tobacco paper, 2 ozs. of Gishurst compound, a little sulphur, and a little soot and lime were all boiled-up together, and stood two days and two nights. I dressed the Vines twice, also a late vinery and Peach house. I covered-up the border at twice fearing it would heat, and started the Vines on the 1st of January, when I found the result I have mentioned. I have well examined the roots and find they are quite alive and full of sap. The Vines are quite a mystery to me and all my fellow gardeners.—A Constant Reader.

[A number of years ago we chronicled how Vines and Peaches in a large place were nearly killed, and no reason could be assigned except the dressing. We can think of nothing else. The boiling of materials makes a great difference, and if the wood were unequally ripened, we should not be surprised. What say our readers? If the roots had not been examined, we might have given that for a reason.—Eds.]

RABBITS AND APPLE TREES.

Do cordon Apple trees breed rabbits, as the barnacle, according to our ancient mariners, did barnacle geese? I begin to think so, for till the frost and snow last Christmas I saw no rabbits; but then came the storm of snow and rabbits, their traces like as if a multitude had spent the night near my Apple trees. They commenced operations by biting off all the buds—the frost some 12° or 14°. The next operation was taking off the bark from the young shoots; then came 20° to 26° of frost, and all the shoots were eaten and the stems barked, so that my trees were skeletons. I believe myself to be a victim to fine writing, for I think I read in your columns (no, it must have been in some other periodical), that cordon Apple trees would make a fortune for a market gardener if properly trained. I had had some planted in my walled garden for two or three years, and, although they had not borne abundantly, yet they gave me fine fruit, and looked pretty when in bloom; but this market-garden business awoke me as from a sleep, and so the last two years I planted cordons rather extensively, and now, when just on the point of reaping the fruits of my labour, the rabbits are before me.

I could not protect without a large quantity of bushes or straw, and the cosmetics—painting, with the usual odorous compounds—I found not of the slightest use. The only safe method of growing cordon Apple trees is in a walled garden, for if fenced with wire, rabbits burrow under the fence, unless the lower portion is buried. It is very remarkable to find in severe weather the great love for Apple trees shown by hares and rabbits. Some old men have told me that hares have been traced in the snow three miles and upwards from a preserve to a garden. I quite credit this, for whereas I had not seen a hare till the 22nd of last December, I was astounded to see their numerous traces from that period. If anyone wishes to see rabbits and hares by moonlight in severe weather, he should plant cordon Apple trees in an unfenced garden.—A Rabbit Victim.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Continue the preparation of ground for crops in general, but beware of carrying it on when the soil is wet; better be a fortnight late with any crop. Where the soil of the kitchen garden is light and sandy it is best dug or trenched some weeks before it is wanted for certain crops, especially Broad Beans, which like a firm hold of the soil. Give all *Asparagus* beds a slight salting; this should be done after soiling, the rains will carry the salt down. A bed of early *Cabbages* may be sown on a warm border, also shortly some *Leeks*, Green *Kale*, *Savoys*, and *Brussels Sprouts*, for early purposes. *Onions* should be sown as soon as possible; choose a piece of ground which has been deeply dug or trenched, and well manured, throw it into beds, sow it when dry, cover thinly, and roll hard, except in the case of clayey soil. It will be well to strew cinder ashes or very sharp sand amongst the stems of the early *Peas*, as the slugs, from long confinement, will be unusually voracious this spring. Let the *Parsnips* be sown as soon as the ground is in a fit state. Replant all old Box edgings, and keep them for the future neatly and closely clipped. Repair all other edgings to walks, and take advantage of the gravel walks being soft to turn them, and to roll them firmly. Much may now be done in a day, and in a better manner than when the surface is hardened by parching winds and hot sun, and the walks will be more easily kept in good condition afterwards. Keep correct memoranda of all proceedings, the quantity and quality of manure made use of for all crops, the state of the soil when applied, and the success or otherwise of the application. The knowledge how a manure has acted on certain soils in other seasons, will be found useful as a means of discovering the cause why results do not always accord.

FRUIT GARDEN.

I shall suppose the pruning, tying, and training of espaliers and all other fruit trees has been brought to a conclusion, except, perhaps, as regards a few Peaches and Nectarines, and that the trees which are infested with Moss and Lichens have been dressed as before recommended. It will now be very interesting to notice the daily progress of the bed which, considering all matters, is seldom observed in finer condition for future prospects. Every advantage must be taken of drying windy days to stir and hoe the surface, and a sharp look-out must be kept to prevent injury to the buds of wall trees now in a forward state. Where nets or bunting cannot be procured for protecting the blossom, suspend from the top of the wall to the bottom of the trees a quantity of straw or hay ropes, made with a few projecting loose straws; dry fern or spruce branches may be nailed over the branches of the trees with advantage, Look to the Fig trees; prune and train those requiring it. tying or bending the strong shoots down, which will induce them to push out a number of very short-jointed bearing shoots.

FLOWER GARDEN.

All grass lawns should now have a thorough rolling, and all turfing repairs should be completed forthwith. Where it is absolutely necessary to cut the edges of walks, let it be done now, and as soon as accomplished run a heavy roller several times up and down the edges to soften the cut line. All edges should, if possible, have a slight inclination towards the walk, and they should only be fresh cut in consequence of irregularities in the line. High-kept lawns should have a single mowing soon after rolling. The severe weather we have had nearly up to the present time has precluded any floricultural operations being carried forward. There never was, however, a better time for collecting and forming composts, and preparing for future use, by frequent turning, those which have already been made. The amateur has no excuse if his soil heaps have not been frozen through and through during the severe weather, and the whole tribe of insects and their eggs completely exterminated. Auriculas should have the decayed and decaying leaves carefully removed, and, if not already applied, a top-dressing of fresh compost; a gradual increase may take place in the supply of water. Carnations and Picotees in pots require to be kept clean and comparatively dry, and they should have the surface of the soil frequently stirred. The compost for potting them in

due time should be prepared; it may consist of the following ingredients—viz., one-half of turfy loam, one-fourth of manure reduced to the state of fine mould (cow dung is to be preferred), and one-fourth of coarse gritty sand, which may be road or river sand. Even small stones may be allowed for drainage, when the necessary waterings need give rise to no unpleasant apprehensions.

GREENHOUSE AND CONSERVATORY.

Young plants of Allamandas, Clerodendrons, Torenias, and many other subjects, if encouraged with a little bottom heat and favourable circumstances, will form useful specimens in a few months, and large masses of Statices, than which few plants are more serviceable, will under good treatment be obtained in a short time. The showy Impatiens Jerdoniæ should also be encouraged by every possible means to make wood, and let it be propagated as quickly and freely as possible, for it is very useful for autumn decoration. The dwarf Heliotropes, where sweet-scented flowers are in request, will likewise be found useful for blooming under glass. In fact, where the stock in hand is deficient, as it will be in many places after so severe a winter, not a day should be lost in making every possible effort to provide for what is likely to be wanted. Pelargoniums should be duly attended to in respect to staking and tying out the branches, so as to induce them to form handsome specimens. They will bear repotting the moment blossom-buds are formed at the ends of the shoots. Tender annuals, as Balsams, Cockscombs, &c., may now be sown. They succeed best in a frame, on a gentle bottom heat furnished by means of fermenting materials. Although heat is indispensable for raising these, it is not necessary for flowering them; indeed, most of them would bloom more beautifully if planted out in June in a warm, sheltered part of the garden, than if treated as greenhouse plants. Continue occasional sowings till the end of April in pans placed close to the glass, in a temperature of from 60° to 65°, keeping the soil moist, and shading it from bright sunshine. Care must be exercised to prevent the young plants from damping-off or being drawn up through want of air. As soon as they can be handled prick them off singly in small pots, or place three round the edge of a 4-inch pot, plunging them in a gentle heat till they can be safely trusted in the open borders; or they may be pricked out in rows on a spent hotbed, shading carefully, and giving plenty of air when the weather will permit. To secure fine plants and a profusion of bloom it is of the greatest importance to sow early. Attend carefully to the stock of bedding plants, and pot off rooted cuttings as soon as they are in a fit state for that purpose. Encourage them with a gentle bottom heat and careful management, to make quick growth, for after this season there is no time to be lost with young stock.—W. Keane.

DOINGS OF THE LAST WEEK.

After close sloppy weather we were again visited with a sharp black frost on the night of the 10th and 11th, the first rather unexpectedly showing some 14° below freezing in the morning. The frost has been favourable for rough groundwork, as moving soil, making alterations, levelling, &c., but it has retarded much work in the way of planting, where the roots must necessarily be exposed. A great many young trees and shrubs intended for profit, for ornament, protection, or game cover are much injured when the roots are exposed for some time to a dry parching frosty wind, such as we had on the two days mentioned above. When a number of men are anxious for work a line must be drawn between what is due to them and the ultimate welfare of the trees. To their credit, be it said, most of the great nurserymen send out trees in winter so well packed and secured at the roots, that it is next to impossible they can be injured. Even if a severe frost should reach the roots through the packing, that will do but little injury if light and wind be kept from them. In other nurseries we have seen numbers of fine trees and shrubs taken up, and their roots left exposed for days in frosty weather before being sent out. In such cases fresh roots, fibres, and even large-sized roots must be formed before there is much growth, and this, we have no doubt, is one reason why trees that often break well in the spring after planting begin to become stunted, brown, and shrivel up and die as the sun gains power, there being no root-action to supply the demands of sun and heat on the stem and unfolding shoots.

KITCHEN GARDEN.

For this department refer to the notices of last week. Trenching and turning soil must be the order of the day in the open ground, and preparing for and sowing Beans and Peas, and getting both forward under protection for planting out as the first crops.

Red Lead for Seeds.—In making all such sowings, taking past experience for our guide, we shall coat every Pea with red lead before sowing. A very little lead, as much as may be held between the thumb and two fingers, if these are of average size, will do for a quart of Peas, previously merely damping the Peas a little, or placing water over them for a few minutes, and then draining all the water clean off before applying the lead, and working it all through the Peas with a flat wooden stick, as it is advisable to use the hand as little as possible among the damp lead. If the sower has any cracks or cuts on his hands he had better sow with a rounded trowel or something of that sort, and be careful to leave no lead between the flesh and nails of his fingers. By this mode we have found that nothing will touch the Peas or other seeds so used until the seedlings are above ground; and the singular point is that rows of Peas thus treated seldom have a single hole made in them, the intruders of all kinds, fowl and four-footed, having an instinctive knowledge that what is below is not for them. We have sown rows leaded and unleaded side by side. The first never had a hole made in them, the second in the course of a week, from mice, pheasants, &c., had scarcely a seed left. As the small quantity of lead used merely for colouring would be thrown off by the expanding and ultimately perishing seed leaves, we cannot see how the small quantity of lead could have any injurious property on the crops presented at table. Without netting or anything of the sort, we do not think we lost a seed of any of the Cabbage, Turnip, or Lettuce tribe, to which the red lead was applied. In such instances no more seed should be coloured than it is intended to sow at one time.

Cabbages.—Though, as we stated last week, all the forward crops have greatly suffered, if they have not been quite destroyed in many places, we are glad to hear that where the soil was light and dry the plants have stood well, and will, therefore, be extra valuable. We have been informed, too, that in many places fine beds of seedlings have stood well, and, therefore, there will be a chance of getting Cabbages, though not so early as in the generality of seasons. Those who have no other resources must plant as soon as possible in well-pulverised soil. Where there are the means of placing the plants in a mild hotbed, under glass or other protection, either singly in small pots, or some 4 inches apart, in rich soil to be raised with balls, and in either case transferred with well-established roots to nice, friable, pulverised soil, much time will be gained. All this labour may to some people seem next to thrown away; but, then, they cannot look upon a nice crisp Cabbage early, with the heart just turning yellow, as we do. Whilst we regret that so many of our cottage gardeners are deprived by the frost of what would have been to them a source of wholesome food, we rejoice that others are more fortunate, and thus a better price will be obtained for what they choose to sell.

An old friend of ours when there was something like a general failure of some particular vegetable or fruit, used to express his satisfaction and something like thankfulness, that he was no worse off than his neighbours. There may be something soothing in knowing that we have companions in such failures and disappointments. We never could see, however, how the failures and disappointments of others joined to our own could help us in the least, or form any source of consolation. In the present instance, as respects the standing or the failing of the Cabbage tribe, we believe there is little room for glorying or boasting of the success, as the most of it would depend on the peculiarities of the weather, of the soil, and of position. If the readings of thermometers be at all correct, there have been wonderful variations of temperature this winter, in what we should be led to consider similar circumstances. Strangers coming here on such days as the 11th, can hardly manage to keep themselves warm. Even a mile or half a mile will often make a great difference as to our sensations of heat and cold.

FRUIT GARDEN.

See previous weeks' notices. During the week there would be about one hour and a half of sunshine, and that would do wonders for Peaches in bloom. We need not, however, repeat what has lately been stated. Anything like fruit-tree planting has been out of the question, but pruning and nailing could be proceeded with. In all weather fair above head, there is little

difficulty as respects pruning; a man can keep himself comfortable at that. But what is the use of nailing when the fingers cannot hold the nail and shred comfortably? We have pretended to nail with the trees covered with snow, and the snow drifting enough to smother one. What was the use of such waste of labour power, with work needing to be done under shelter? We are sorry to say that such ill-timed work is frequently beyond the control of the gardener. Some proprietors, if they set their mind on having certain work done, have no idea of a stoppage from that work, let the weather be what it may. Years ago we made two visits to a large place within the space of two or three months. On the first occasion men with their coats buttoned to the chin as a defence against the heavy sleet and rain, were wheeling a large heap of dung on to the quarters with the wheel of the barrow up to the axil in mud, and doing great damage to the walks. On the second occasion, the same men were in some danger of sun-stroke in washing and cleaning Vines in a vinery in a bright sunny day. Leaving other considerations out of view, there could be little fitness or economy in such ill-directed, ill-timed labour.

Heating.—We have just had fresh piping put into a small division of a vinery. We could not at present enter on the large one-boiler system. For this compartment and other places there was a small separate boiler. In the vinery part we had only one pipe round underneath the stage, helped by shallow zinc reservoirs which we connected afterwards with this one pipe. These and the pipes had become too worn-out to be cobbled or mended. We could not help ourselves as to having the fresh pipes going round underneath the stage, but we carried out one of the ideas which we have often advised others to adopt, and that is to have as many flow-pipes as possible, and these on a level. As the flow and return pipes were there, and not far apart, there was joined to each a three-flow outlet syphon, so that we had three pipes round instead of the one. These three pipes are on a level with each other, and rise regularly some 3 inches from the point of junction with the flow to the outlet syphon at the return, and an open air pipe is there inserted. The three pipes round therefore act as flows. They heat well and equally, and there is only a very short return from whence the three pipes terminate at the highest point. We are aware that in theory there are some objections to this mode. These and other matters as respects heating need ventilating. All we can say at present is that we are satisfied, and that we have advised and adopted the plan from finding that in stacks of pipes above each other the highest pipes are always the hottest.

ORNAMENTAL DEPARTMENT.

Our time has been chiefly employed in *alterations and groundwork*, altering what had been done years ago. There is hardly a place where much may not often be done in this way. Different people have not only different tastes, but the same person may change his taste as often as he pleases. At one time the proprietor may rejoice in mounds, rough work, and the wild and tangled picturesque appearance, and such will ever present a contrast to the richest and most dressed parts of the pleasure ground. At another time such a scene, however pretty, diversified, and picturesque, may become monotonous, and cease to yield the pleasure it once did, and something of the gardenesque may be more desired, where the mounds, and the tangle, and the wildness, and variety may be replaced by the smooth lawn, with specimen shrubs and trees that will have room to grow and to show off their separate beauties. Whoever pays for such changes has a right to consider the improvements. They therefore do good in two ways: they give satisfaction to those who wish to have them made, and they often give employment when that is scarce. Everybody likes change. We often think if we possessed an estate, and chiefly resided on it every day of the year, we should become tired of it, and of seeing things day after day in the same position. We believe that fine gardens and noble conservatories are generally more appreciated by visitors than by the resident proprietors. Elegance and novelty are combined in the case of the former; the elegance is combined with an irksome sameness in the case of the latter. Hence, the advantage of all changes. We can easily imagine that the finest flower beds, the most elegant plants growing in a bed in a conservatory, the finest tree Ferns standing always in the same spot in a fernery under glass, in time lose more than half their charms to the resident proprietor, just because he sees them always in the same place and under the same circumstances.

We are apt to forget that the most pleasing objects seen day after day become at last irksome and insipid. Variety, freshness of combination, would often do wonders where there are the labour and other means at hand for carrying them out. Thus, flowers are always delightful in a common greenhouse. To the visitor all is novel. The same arrangement day after day becomes tiresome to the proprietor. Hence, in the case of a fair-sized conservatory, where beauty, elegance, and good taste, combined with a continued and growing interest in it by the proprietor, are to be first considerations—judging from our own feelings, were we similarly placed, we would plant out little except the climbers, but we would have beds deep enough so that the pots used might be covered with moss, and a band of Lycopods round, and then by arranging the plants differently every fortnight or so, the fresh combinations would in everything essential make a fresh house. Even in a greenhouse, where no attempt is made to conceal the pots, much may be done to dissipate monotony by changing the forms and sizes of groups and combinations. For resident proprietors a simple change is often as good as a real improvement, and on this account all changes that make variety are desirable. The plan of a flower garden may remain the same, and yet some variety may be produced by planting it differently every year. Were the design changed every year it would be better still. Few can equal our coadjutor, Mr. Robson, in this respect, but we have often thought what a source of pleasure it must be to the proprietors of Linton Park to be able to look on two fresh plans of the principal flower garden every year. Even that might not be sufficient variety for some people who have a dread of the monotonous. The subject is too large to admit of our doing more than giving these passing hints.

We shall be anxious to commence turfing before long, and then it will give us no trouble in summer.

Some main features as respects out-door work have already been alluded to. The forcing of flowering plants has also received notice lately.

Bulbs.—There are complaints about these not doing well, and the flower stems being so short and dumpy. After duly potting, &c., the first essential to success is having the vessels filled with roots, whether pots or glasses, before the flower stem begins to move much; before that takes place the bulbs will be best in a dark place, such as a cupboard in a room, or any sheltered place out of doors where they can be covered up. Again, if the stems do not rise freely after the bulbs receive the heat of a sitting-room, a paper funnel placed over them, or even a reversed pot, will greatly assist to elongate the stem, and thus give room for the flowers to expand.

All forward bulbs out of doors would be better in such weather of a little protection, such as cloths or mats over hoops, or a little dry soil or ashes over the bulb, or even evergreen twigs securely stuck in over the beds. The soil should be well mellowed for Ranunculus and Anemone planting; Auriculas should be top-dressed with rich light compost in mild weather, and the plants kept from rains; and Carnations and Pinks defended from cold, slugs, and mice, not to say anything of rabbits and hares.

Many of our window and small-house gardeners will now be thinking of *potting and repotting* their favourite plants; numerous young growing plants will need more room, and many, as Geraniums and Fuchsias, breaking after being shortened back a little, will want to have much of the old soil cleared away, and to go at first into pots of the same size as before, or even smaller. The following are great helps to success—1st, See that the soil and roots of a plant are moist enough before repotting. If you put a dry ball into fresh soil it is next to impossible to wet it again by common watering. 2nd, See that the pots used are clean and dry. If not, besides other disadvantages, the ball will not come out clean and whole, but it will hang like birdlime to the sides of the pot. 3rd, Be sure that the soil used is fresh, well exposed to the air, warm, and not too fine. In cold weather the necessary warmth can easily be obtained by placing it near a fireplace, where no other means can be resorted to. It is well that the soil for all in-door plants should average about 60°. Then, as to roughness, the plants will thrive all the better if, for 4 and 6-inch pots, fully half of the bulk of the soil should range from the size of peas to that of field beans, mixed with the finer particles. A little of the rougher should go over the drainage. There is no better drainage then a zinc cap over the hole, or a good crock with the rounded side downwards, and in either case smaller pieces of broken pot round it and over it, and a slight layer of green moss over all, the roughest compost over the moss. Finally, avoid everything that will give a check to the plant, either by

subjecting the roots to extra cold water or cold soil, or the tops to a continued cold atmosphere, whilst they have previously been used to a temperate one. Sowing and cutting-striking indoors must receive future attention.—R. F.

TO CORRESPONDENTS.

*** We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By doing so they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

N.B.—Many questions must remain unanswered until next week.

Books (*E. P.*).—"The Pine-Apple Manual." You can have it free from our office by post if you send thirty-two post-office stamps with your address. (*M. Brown & Co.*).—Hogg's "Fruit Manual." Last edition, 1866. Price 5*s*. Out of print. New edition preparing.

Fruit Manual (*W. C.*).—The new edition is preparing for the press, and when ready will be advertised.

Iron Pipes Choked (*W. A. G.*).—As you have a pipe to empty the boiler, we would risk placing from one half to 1 lb. of sal ammoniac in the supply cistern, getting a good heat up, and after a day or so draw off the water, fill with fresh, and repeat the dose. We advise this more in theory than as warranted by our own practice. An ounce of sal ammoniac put now and then into the supply cistern would greatly prevent furring, but we are not so sure that it would dislodge it when formed. We are much surprised to learn that the water circulates so badly in your pipes, after being only four or five years in use. We have seen pipes rather badly furred, and the material inside hard, after being thirty years in use. We think you must have a peculiar water for the pipes to be crusted inside after such a short time. It is just possible there is a considerable quantity of mud in the boiler and pipes, and emptying as stated above would relieve you of that. We almost think there must be something else wrong, as so long as there is waterway the pipes will heat. We once saw 4-inch pipes so furred that there was not a 2-inch passage, and so hard, like iron, was the incrustation that we had little faith in anything moving it, and we counselled fresh pipes. In one other case that came under our observation, the pipes were much choked up, but the incrustations were of a softer, moveable character. The owner dreaded going to the expense of new pipes, so we advised taking up the pipes, cleaning them with a wooden pole nearly their own diameter, and as the joints had been done with iron filings, instead of attempting to get them out, the collar and joint were cut, and a sliding collar put over to connect the pipes. In ordinary cases, with a little sal ammoniac put in the water, the pipes may last half a century, and scarcely show a sign of furring. It is always advisable to empty boilers at least once a-year, but the oftener the better.

Primulas after Flowering (*Emily*).—The plants will flower a second year, and should, on their going out of flower, have all the flower-stalks and any yellow leaves removed, be kept rather dry, but not so as to cause the leaves to flag much, and be set on a shelf in the greenhouse, or other light, airy position. In June they may be set out of doors in a position shaded from midday sun, and on coal ashes, so as to prevent worms from entering the pots. Keep them sparingly watered, and remove all flowers as they appear. In August repot them, removing any loose soil, or that which can be taken away without much injury to the roots, giving a moderate shift, and draining well. After potting place the plants in a cold frame, setting the pots on ashes. Water the plants moderately, and admit air freely, and they will commence flowering in September, and continue to do so up to Christmas. We do not keep the old plants, but sow in March to raise plants for autumn and winter flowering, and sow again in July for spring bloom. The plants have finer foliage and larger flowers than those kept over a year.

Fancy Pelargoniums (*E. J. L.*).—If the plants are bushy or well furnished with shoots, we would not remove the flower-buds now showing, but if they are not compact in growth pinch them. Keep the plants near the glass, with plenty of air, but safe from frost.

Planting Hollyhocks (*Idem*).—Pot them now, and defer planting out until April, hardening well off previously. They would succeed better now in a cold frame than in a greenhouse. We fear they would not do any good in the ground by the Ash tree. Give them a good rich soil in an open situation, better if sheltered from winds. Considering that you have had all the Ash roots dug up, and that the tree is to the north of the border, the Hollyhocks might do fairly, but we should give them a more suitable position if possible. A sieve of Apples is seven imperial gallons.

Selection of Grapes for a Vinery (*A Young Grape Grower*).—You do not say for what purpose you wish your selection. Alicante and Gros Guillaume are late Grapes, Trovêren Frontignan and White Nice are mid-season varieties, and of the last two we would not have more than one in a selection of twelve. We would have two Alicante instead of one, and besides the other three named, two Lady Downe's, two Bowood Muscat, two Mill Hill Hamburgh, and one Trebbiano. Mrs. Pince's Black Muscat, and Madresfield Court Muscat, are amongst the finest of late Grapes, and ought to be in every selection of such, but you have forestalled, and, therefore, limited our selection.

Camellia Buds Falling (*W. O. M.*).—We do not think the heating has anything to do with the falling of the Camellia buds. It arises from another cause—we believe from imperfect root action. We would repot them as soon as they go out of flower, or, if they do not flower, about the middle or end of March, turning them out of the pots, removing as much of the old soil as practicable from amongst the roots, picking it out with a pointed piece of wood, and preserving as many of the fresh roots as possible; drain the pots well, and pot the plants firmly in the top inch layer of a pasture, where the soil is a light loam, chopping it up rather small. Keep the soil moist, but do not make it very wet until the plants are growing freely, then water them copiously, and maintain a moist atmosphere with a moderate amount of air. We do not think the buds will fall next winter. Do not place the plants out of doors in summer, but after the buds are set keep them in a cool airy house. A house slightly shaded in summer is most suitable.

Pear Trees Infested with Scale (*C. A.*).—Your trees are suffering from scale, and we do not wonder at the absence of fruit. Unnail, or if tied loosen, the branches from the wall, and brush every part with paraffin oil. A solution of Gishurst compound, 8 ozs. to the gallon, will answer, and is not so offensive to apply. The earlier the dressing is done the better. Your trees being badly infested, it may be necessary to repeat the application next autumn after the leaves fall.

Value of Camellia fimbriata (*An Old Subscriber*).—The plant being "rather one-sided," is not worth nearly so much as if it had been symmetrical. Many would not buy it on that account, but if there are branches on that side, so that a year or two's growth would secure its becoming furnished, it is worth £20, presuming it to be in good health, and well furnished with branches.

Fruit Trees (*R. W.*).—Mr. Abbey informs us he has grown and now grows all the kinds named in his former article, and at page 85. The Apples, Pears, and Plums are grown as pyramids. They are kept closely pinched, many being 7 feet 6 inches high, and 3½ feet to 4 feet through, and this four years after planting. They have not been lifted since they were planted; the lifting he considers unnecessary, as the trees are 6 feet apart, but those of the sizes named are 9 feet apart. They are masses of flower-buds. The Pears are on the Quince stock, and the Apples on the English Paradise.

Greenhouse Plants not Thriving (*J. C.*).—The cause of the plants not thriving we should attribute, as you do, to the fumes given off by the hot-water pipes. The height of the house, we are confident, has nothing to do with it, for we have one considerably higher, and the plants thrive admirably. We think it is due to the white lead used in the preparation of the stone-coloured paint with which the hot-water pipes are coated. Nothing more is required to keep the pipes from rusting than painting with oil and a little lamp black. We should endeavour to remove the paint by wrapping them in cloths dipped in a solution of 8 ozs. of soft soap and 1 lb. of soda in a gallon of water. The pipes will need to be kept wet by the solution for at least twenty-four hours; therefore, the cloths must be watered with the solution, pouring it on them with a watering-pot. A strong solution of guano will answer the same purpose. Scrape off the paint when loose, and wash with hot water.

Leaf Soil (*Idem*).—The small grubs are common in leaf soil, and we do not think they are injurious to the roots of plants. They disappear if the leafy matter be turned over a few times, especially if the weather is frosty and dry. Place the soil under cover to dry before using it for potting.

Slow-combustion Stove.—At page 101 2*s*. 4*d*. should be 2½*d*.

Glass Gardens (*S. Gosfield*).—The writer you name must have meant Gilbey's glass orchards, manufactured by Messrs. Dennis, of Chelmsford, or glass walls. You may hear about the latter if you write to Dr. Newington, The Vineyard, Ticehurst, Sussex.

Top-dressing Potatoes (*J. B. K.*).—Apply 8 cwt. per acre of guano. Hoe the surface slightly after applying it.

Seeds from Australia (*J. H.*).—Solanum species is probably a greenhouse perennial. Sow in light sandy soil early in March, place in a hotbed, and remove to the greenhouse when the seedlings are established in small pots. Leptospermums have mostly white flowers, and are evergreen greenhouse plants. Sow in sandy loam and peat, and place in a hotbed in March. Geodia latifolia is a greenhouse evergreen shrub with yellow flowers; sow in sandy peat and loam, and place in a hotbed in March. Billardiera cymosa is an evergreen greenhouse climber; sow in sandy peat and loam in a mild hotbed in March. Stenocarpus sauignus is an evergreen greenhouse shrub, with greenish yellow flowers; sow in a hotbed in March in sandy peat and loam. Kunzea (now Metrosideros) corifolia is a white-flowered greenhouse shrub, and to be treated like the others. Prostanthera nivea is a greenhouse evergreen; sow in sandy peat and loam in a mild hotbed in March or April. Leucophyta Brownii we do not know. It is syngeneaious. Eucalyptus Stuartiana is a greenhouse evergreen tree; sow in heat in sandy peat and loam. Indigofera australis is an evergreen greenhouse shrub with pink flowers in spring; sow in peat and loam in a hotbed. Of Enchylaena sarmentosa and Erimephila longifolia we cannot advise. Hakea saligna is a greenhouse evergreen shrub; sow in sandy peat and loam in a hotbed. Pomaderris elliptica is a greenhouse evergreen shrub with creamy flowers, not unlike a Ceanothus. Elæocarpus cyanaus is an evergreen greenhouse shrub with white flowers. Callitris cupressiformis is an evergreen coniferous tree, nearly if not quite hardy; sow in heat in sandy loam. Lasiopetalum Baueri is a greenhouse evergreen shrub. This, as well as all the others, we should sow in March or early in April in sandy peat and loam, and place in a mild hotbed of 70° to 75°, keeping the plants, when up, near the glass, and when they have made two or three rough leaves pot off singly in small pots. Return to the hotbed, and keep rather close and shaded for a few days, then admit air freely, and remove to the greenhouse when hardened. Pot as the plants fill the pots with roots.

Pear-tree Insect (*A Subscriber*).—Probably it is the Slimy Grub (Selandria æthiops). It does great damage to the leaves in summer and autumn. There is not any remedy so effectual as frequent dustings of the leaves with quicklime. Lime water and a solution of soft soap have been found useful at the rate of 2 lbs. of soft soap and a peck of lime to thirty gallons of water. Tobacco water—2 ozs. of tobacco to the gallon of water—has also been found satisfactory. You could graft any of the Acers on a Sycamore. We do not know of a weeping tree that would grow on it. They are all too large for gardens, though fine for pleasure grounds.

Cyclamen Treatment (*A Constant Reader*).—Keep the seedlings in the greenhouse until June, then remove them to a cold frame; keep them rather dry, in August repot, and in September place them in a house near the glass with a temperature of 45°. They will flower next winter and spring if in good health. They are too small to flower now. If weak and poor in foliage we would encourage growth by a gentle heat, as you do the seedlings.

Statice Holfordi not Flowering (*K. M. B.*).—The cause of failure is, we think, a deficiency of heat. Your placing the plant in the stove was not, perhaps, until it had shown the spikes which from the excite-

ment consequent on the higher temperature was sufficient to cause them to fail. It will not do in a cool greenhouse, but does admirably in a warm one. Keep it near the glass, or afford plenty of light, and give no more water in winter than enough to keep the foliage fresh.

NAMES OF FRUIT (*Bolton Gardens*).—No. 1, Winter Franc Réal, a stewing Pear; 4, Knight's Monarch, a fine specimen of it, probably grown against a wall. The others we do not know. They appear to be worthless, except for stewing.

NAMES OF PLANTS (*Mary*).—We cannot name plants from leaves only.

POULTRY, BEE, AND PIGEON CHRONICLE.

THE LANCASHIRE MOONEY.

THERE is one point in connection with the breeding of Silver-spangled Hamburghs which I should like to bring before the notice of breeders and fanciers of this most beautiful variety, and that is the practical ignoring in the "Standard of Excellence," and therefore by our judges, of that sub-variety called the Lancashire Mooney. It is a well-known fact that it is from the pure-bred Mooney we get the most brilliant, the largest, and the most perfect moons or spangles, and it is equally well-known that the finest specimens as stock birds are hen-feathered, and as such are considered, according to the present standard, defective in plumage and not admissible as show birds. In "The Poultry Book," it is mentioned as a characteristic of the pure-bred Silver Mooney that they throw hen-feathered cocks, this tendency being exactly reversed in the two varieties; the Golden Pheasant and the Silver Mooney throwing hen-feathered cocks, such never being the case in the Golden Mooney or Silver Pheasant. Mr. Tegetmeier is very decided as to the propriety of having pure Mooney blood on one or other of the sides if you wish for brilliant plumage. Mr. Beldon also, I know, considers this a *sine quâ non* in the selection of stock birds; in fact, he has informed me he prefers the dark-necked cocks in every respect. Now, all this may be considered merely as a matter of taste, but it is more serious, for, as the standard is now decided, we cannot hope to see this beautiful Hamburgh brought up to that real standard of excellence.

According to the present system our judges insist on the cock having the deaf-ear opaque-white, with the tail white and spangled at the end of the feathers, the deaf-ear of the hen being also white. Now, there is no doubt such markings look very beautiful, but all breeders of this variety know the almost insuperable difficulty of obtaining a beautifully-marked cock having the deaf-ear opaque-white, one of the characteristics of the Silver Mooney being a small deaf-ear streaked with pink or red. By crossing with the Silver Pheasant we obtain exactly what we want, or rather what the judges demand, a large deaf-ear of the most beautiful milky whiteness. Whenever I see a Silver-spangled Hamburgh fowl, however beautiful his plumage may be, with a large white deaf-ear, I at once set him down as a cross between the Pheasant and the Mooney. By careful breeding by such experienced men as Mr. Beldon, the white deaf-ear and clear tail may be had on a certain per-centage of the Mooney stock, but I am afraid these are exceptional birds. Again, is it not true that we cannot get size unless with the Pheasant blood, and that the big birds, other things being equal, have the best chance in the show pen?

Some may ask, What, though we cross, and are obliged to cross, our Mooney with the Pheasant to obtain our prize birds—what harm? Simply this—these crossed birds are useless as stock birds, always throwing badly-marked pullets, which, as Mr. Tegetmeier has pointed out, will not stand the test of even one moult. Those birds ranking first in the prize list are, of course, bought up by amateurs like myself, who are not up to all the secrets of Hamburgh breeding, the consequence being a constant check to the perfect breeding of this most beautiful of all the Hamburghs. Here we have the anomaly of the best prize bird being the worst stock bird. Some experienced breeders, with the laudable desire to save the Mooney from utter extinction, breed from two yards, one for the cockerels the other for pullets; but this system must be vicious, and no crossed birds should be admitted into the prize list unless in their true character. Why cannot committees give a small prize, even a recognition, to the best hen-feathered cock, or, what would be better, to the best pen of the sub-variety—the Lancashire Silver Mooney? Let it be better known that there is a distinction between the Mooney and the Pheasant, that the small deaf-ear, stained with pink or red, a rather coarse head, and rather dark tail, mean a Lancashire Silver Mooney, and that a large deaf-ear of opaque whiteness, with a neatly-chiselled head and clear tail, can only be found in the Silver Pheasant. —JAMES MORE, M.D., *Rothwell, Northamptonshire.*

RESULTS OF POULTRY REARING.

COLOURED Dorkings are often considered very delicate. I do not find them so. Last year I hatched seventy-eight, and reared seventy-seven. I generally hatch about one hundred chickens, and I can certainly say I have never yet lost four per cent. of them. This may appear strange, but it is nevertheless true. I need not say that every care is taken of the birds. They are fed every hour from early in the morning to late at night, are never allowed to go out till the dew is off the grass, and are kept warm and very dry. The latter is very important, but not more so than not breeding from birds too closely related. I am often astonished at the great losses amongst chickens that I see and hear of, and feel confident that if the above hints were followed, very few chickens would die. I do not breed after May, as I find the chickens then are weak. My feeding is the same as is continually recommended in this Journal.—T. E. KELL, *Wetherby.*

PORTSMOUTH POULTRY SHOW.

THIS was held on the 7th, 8th, and 9th inst., and was a decided success. The following awards were made.

GAME.—*Black and other Reds.*—1, W. H. Stagg, Netheravon. 2, Capt. H. Adney, Goodworth, Clatford (Black Reds). *hc*, G. Bainton, Southsea (Brown Reds); R. Hall, Cambridge (Black Reds); W. H. Stagg. *c*, C. H. Ames, Henley (Black Reds). *Any other Variety.*—1, S. Matthew, Stowmarket (Duckwing). 2, G. Potts, Chartham (Pile). *hc*, R. Hall (Duckwing).

COCHINS (Any variety).—1, J. Watts, Birmingham. 2, J. Rogers, Hastings. *hc*, J. Pares, Postford, Guildford; C. Howard & Nichols, Peckham; J. K. Fowler, Aylesbury; H. Dent, Cosham. *c*, J. Long, Plymouth; H. Dent.

BRAHMAS.—*Dark.*—1, H. Dent. 2, J. Watts. *hc*, F. James, Peckham; H. Dent. *c*, Rev. J. Ellis. *Light.*—1 and Cup, J. R. Rodbard, Wrington, Bristol. 2, F. Crook, Forest Hill. 3, H. M. Maynard, Holmewood, Ryde. *vhc*, A. O. Worthington, Burton-on-Trent. *hc*, T. Turner; J. Pares (2); W. Masland, Milverton; F. A. Dean, Moreton-on-Lugg; F. Crook. *c*, T. Turner. (The whole class commended).

DORKINGS.—1, J. Smith. 2, Lord Turnour, Shillinglee Park, Petworth. *hc*, J. Bargeman, Dorking; J. Chesman, Rounham, Southampton.

SPANISH.—1, F. James, Peckham. 2, Howard & Nichols. *hc* and *c*, Rev. M. Rice, Bramber.

ANDALUSIANS.—1, 3, and Cup, T. Moore, Landport. 2, W. Wildey, Cosham. *hc*, E. Tonkins, St. Saviour's, Jersey.

HAMBURGHS.—*Gold-pencilled.*—1, F. Pittis, jun., Newport, Isle of Wight. 2, H. Pickles, jun., Barby. *hc*, H. Pickles, jun.; W. H. Tickner, Ipswich. *Silver-pencilled.*—1, J. King, Oxford. 2, H. Pickles, jun. *hc*, H. Pickles, jun.; J. Barter. *Gold and Silver-spangled.*—1, H. Pickles, jun. (Silver). 2, H. M. Maynard. *hc*, Mrs. Woodham, Romsey (Silver) (2); C. Windebank, Cosham; G. Potts (Silver). *c*, N. Barter, Plymouth (Silver).

FRENCH VARIETIES.—1 and Cup, W. Dring, Faversham (Houdans). 2, Rev. N. J. Ridley, Newbury (La Flèche). *hc*, Rev. N. J. Ridley (Crève-Cœur); Hill and Co., Brighton (Houdans) (3). *c*, H. S. Fraser, Liphook.

BANTAMS.—*Game.*—1 and 2, F. James. *vhc*, P. H. Jones. *hc*, J. Pares; G. E. H. Elliott, Ryde; J. W. Kellaway, Merston, Isle of Wight; C. J. Spary, Ventnor; G. Potts; G. Mante, Chichester; W. B. Jeffries, Ipswich. *c*, Master J. Stevenson. *Any variety except Game.*—1, M. Leno, Markyate Street (Laced). 2, H. M. Maynard (Black). *hc*, Lady S. Turnour, Shillinglee Park (Japanese); H. M. Maynard (Black); M. Leno (Laced); N. Barter, Plymouth (Gold-laced); J. Watts (Japanese); G. F. Hodson, North Petherton.

DUCKS.—*Aylesbury and Rouen.*—1 and 2, J. K. Fowler, Aylesbury. *hc*, Mrs. S. J. Maberley; J. Pares; A. Belcher, Dorking. *Any other Variety.*—1, F. Pittis, jun. (East Indian). 2, C. N. Baker, Chelsea (Carolina). *hc*, E. S. C. Gibson, Ryde (Mandarins). *c*, E. S. C. Gibson (Carolina); J. M. Freeman, Lymington (Brazilian) (2).

GEESE (Any variety).—1, Mrs. Ford, Shirley (Toulouse). 2, Sir H. P. De Bathe, Chichester (Sebastopol). *hc*, J. Pares (Sebastopol); G. Pittis, Wymering.

TURKEYS (Any variety).—1, Mrs. J. Mahew, Great Baddow. 2, A. Belcher, Dorking. *hc*, Mrs. M. E. Hadden, Landport (2).

ANY OTHER VARIETY.—1, J. Hinton, Warminster (Silver Poland). 2, Rev. N. J. Ridley. *hc*, C. Maggs, Melksham (Black Hamburghs); J. Pares (Japanese Silkies); A. Cruttenden, Haywards Heath (Golden); H. Pickles (Poland) (2); T. P. Edwards, Lyndhurst (White Crested Polands); P. H. Jones, Fulham (Silver Polands); C. Nicholson (Ancona). *c*, S. J. Perry, jun.

SELLING CLASS.—*Cock or Cockerel.*—1, H. Dowsett, Fleshey. 2, Rev. N. J. Ridley (Brahma). *hc*, C. F. Wilson, Totton (Silver-pencilled); G. Potts (Pile); L. W. King (Spanish); T. P. Edwards (Poland); P. W. Jones (Dorking); J. R. Rodbard (Partridge Cochin); H. Bainton (Houdan); Howard & Nichols; W. Westcott, Landport. *c*, O. W. Hoare (Light Brahma). *Hens or Pullets.*—1, H. Dent, Cosham (Cochins). 2, Howard & Nichols. *hc*, Brown & Smith, Gosport; W. Hoare (Light Brahma); H. Pickles, jun. (Poland); Capt. A. Adney (Game); J. Howard, Cosham (Dorking); M. Leno (Light Brahma); G. Murray, Purbrook (Dorking); F. James (Spanish); H. S. Fraser, Headley, Liphook (Houdans); W. Westcott. *c*, Brown & Smith; H. M. Maynard; W. Fielder, Southsea (Game Bantams).

PHEASANTS (Any variety).—1, J. K. Fowler. 2 and *hc*, M. Leno (Golden and Bohemian). *c*, J. Payne, Landport (Silver).

Extra prize for the greatest number of points in the Poultry classes.—Equal Mr. J. K. Fowler and Mr. F. James.

PIGEONS.

POUTERS.—1, E. J. Dew, Weston-super-Mare. 2, P. H. Jones. *hc*, H. Yardley, Birmingham.

BARBS.—1 and *c*, H. M. Maynard. 2, J. C. Ord, Pimlico. *hc*, H. Yardley.

CARRIERS.—1, H. Yardley. 2, H. M. Maynard. *vhc*, E. J. Dew.

DRAGOONS.—1, W. H. Mitchell. 2, J. C. Ord. *hc*, P. H. Jones; W. B. Tegetmeier, London. *c*, F. Graham, Birkenhead.

TUMBLERS.—1, E. J. Dew. 2, J. Ford, Monkwell Street, London.

FANTAILS.—1 and 2, H. M. Maynard.

ANY OTHER VARIETY.—1, S. A. Wyllie, East Moulsey (Yellow Runts). 2, W. B. Tegetmeier. *hc*, P. H. Jones (Trumpeters and Jacobins); H. Yardley. *c*, G. H. Gregory (Turbits); H. M. Maynard; W. B. Tegetmeier.

SELLING CLASS.—1, S. A. Wyllie (Yellow Priests). 2, W. B. Tegetmeier. *hc*, H. M. Maynard (Barbs); J. C. Ord (Magpies); H. Yardley; J. Watts; W. Fielder; J. Ford. *c*, H. M. Maynard (Barbs); S. A. Wyllie (Nubians); E. Barnes (Trumpeters).

Extra prize for the greatest number of points in the Pigeon classes.—H. M. Maynard.

CAGE BIRDS.

Norwich.—*Clear Yellow.*—1, W. Walters, Winchester. 2, Moore & Wynn, Northampton. *vhc*, Moore & Wynne; W. Walters; H. Apted, Broadwater. *hc*, H. Apted. *c*, T. Wiltshire; H. Apted. *Clear Buff.* — 1, W. Walters. 2, Moore & Wynn. *vhc*, W. Walters; H. Apted. *hc*, Moore & Wynn; H. Apted. *Evenly-marked or Yellow Variegated.*—1, Moore & Wynne. 2, H. Apted. *vhc*, W. Walters; H. Apted. *hc*, W. Walters. *c*, T. Wiltshire; Moore and Wynn. *Evenly-marked or Buff Variegated.*—1 and *vhc*, W. Walters. 2 and *hc*, Moore & Wynn. *c*, H. Apted.

Belgian.—*Clear Yellow.*—1, A. E. Smith, Gosport. 2, T. Moore, Fareham. *vhc*, *hc*, and *c*, O. Nicholson. *Clear Buff.*—1, A. E. Smith. 2, W. Andrews. *vhc*, *hc*, and *c*, O. Nicholson. *Evenly-marked or Yellow Variegated.*—1 and 2, O. Nicholson. *Evenly-marked or Buff Variegated.*—1 and 2, O. Nicholson.

Lizard.—*Golden-spangled.*—1, 2, and *c*, O. Nicholson. *Silver-spangled.*—1 and 2, O. Nicholson.

Goldfinch Mule.—*Jonque.*—2, W. L. Chapman, Northampton. *Mealy.*—2, Miss Dyer, Portsea. Extra 2, W. L. Chapman.

Any other Canary or Mule.—1, W. Walters (Cinnamon). 2, T. Mann, Camberwell (London Fancy). *vhc*, W. Walters (Crested Norwich); H. Apted (Cinnamon).

British Birds (Any other variety).—1, W. Walters (Dove and Blackbird). 2, O. Nicholson (Silver Starling). *vhc*, J. Jeans, Marchwood, Southampton (Piping Bullfinch); W. Sims (Starling); W. Sivyer, Portsea (Redpole). *hc*, T. Wiltshire (Goldfinch).

Extra prize for the greatest number of points in the Norwich Canary classes.—W. Walter.

Extra prize for the greatest number of points in the Belgian and Lizard Canary classes.—O. Nicholson.

Rabbits.—*Longest Ears.*—1, C. Graville, jun., Thorne. 2, C. King, St. John's Wood. *Black and White.*—1, W. Simmons. 2, G. Bainton. *Blue and White.*—1, J. Quick, St. John's Wood. 2, G. Bainton. *Tortoiseshell.*—1, C. Graville, jun. 2, G. Bainton. *Self-colour.*—1, J. Quick. 2, R. Hall. *Any other Variety.*—1, A. Clayton, Eastfield, Ryde. 2, Withheld.

Extra prize for the greatest number of points.—C. Graville, jun.

Extra prize for the best Rabbit in the Show, C. Graville, jun. Gray doe, ears 2⅜ inches long, by 5½ inches wide, eleven months old.

Judges.—*Poultry:* Mr. G. S. Sainsbury. *Pigeons:* Mr. F. C. Esquilant, Brixton. *Cage Birds:* Mr. A. Willmore, London. *Rabbits:* Mr. E. Owen, London.

WHITEHAVEN POULTRY SHOW.

This was held on the 8th, 9th, and 10th inst., and proved a very successful Show, there being upwards of 500 entries. The following is the prize list:—

Cochin-China.—*White.*—*Cocks.*—1 and 3, R. Smalley, Lancaster. 2, J Sichel, Timperley. *hc*, E. Fearon, Whitehaven (2); J. Weeks, Bootle. *c*, S. Sherwen, Whitehaven. *Hens.*—1 and Cup, J. Sichel. 2, E. Fearon. 3, G. Shrimpton, Leighton Buzzard. *hc*, R. Smalley (2); J. Sichel; J. Weeks (2). *Buff or any other Colour.*—1, J. Cowman, Whitehaven. 2, Mrs. Wilkin, Bootle. 3, Gunson & Jefferson, Whitehaven. *hc*, J. Sichel; E. Leech, Rochdale. *Hens.*—1 and Cup, J. Sichel. 2, Mrs. Wilkin. 3, E. Fearon. *hc*, Gunson & Jefferson; T. H. Green, Belfast; E. Fearon; W. G. Mulligan, Belfast; J. Sichel.

Brahma Pootra.—*Cocks.*—1 and Cup, J. H. Dawes, Moseley Hall, Birmingham. 2, J. Cowman. 3, R. Brownlie, Kirkcaldy. *hc*, J. Sichel; E. Leech; J. Dove, Coniston. *Hens.*—1, J. Sichel. 2, T. Raines, Stirling. 3, E. Leech. *hc*, T. H. Green; J. Cowman (2). *c*, J. Watts, Hazlewell Hall, Birmingham.

Dorkings.—*Silver-Grey.*—*Cocks.*—1, W. Jackson, Bolton-le-Sands. 2, Gunson and Jefferson. 3, Miss Borthwick, Maryport. *Hens.*—1, R. D. Holt, Orrest Head. 2, W. W. Ruttlidge. 3, T. Raines. *hc*, Mrs. Birkett, Workington; W. W. Ruttlidge; R. Smalley. *Dark.*—*Cocks.*—1 and 3, Gunson & Jefferson. 2, J. Fox, St. Bees. *hc*, J. White, Warlaby; S. H. Stott, Rochdale; Mrs. F. S. Arkwright, Sutton Scarsdale; Gunson & Jefferson. *Hens.*—1 and Cup, J. Stott, Healey. 2, W. W. Ruttlidge. 3, J. H. Wilson, St. Bees. *hc*, J. Robinson, Garstang; L. Patton, Taunton (2); Mrs. F. S. Arkwright. *c*, Gunson & Jefferson.

Spanish.—1 and Cup, C. W. Brierley, Middleton. 2, J. T. Hudson, Ulverston. 3, J. Watts. *hc*, W. Paterson, Langholm; H. Beldon, Goitstock; G. C. Wilson, Milnthorpe.

French Fowl.—*Cock.*—1 and Cup, H. Beldon. 2, J. Sichel (Crève-Cœur). 3, W. Boutcher, Notting Hill (Crève-Cœur). *hc*, Mrs. W. F. Wharton, Barnard Castle (Houdan); W. R. Park, Melrose (Crève-Cœur); J. W. Will, Errol; J. K. Fowler, Aylesbury. *Hens or Pullets.*—1, W. R. Park (Crève-Cœur). 2, J. K. Fowler. 3, J. Sichel (Houdans). *hc*, J. Elgar, Osmanthorpe, Newark (Houdans); R. Smalley (Crève-Cœur); J. Sichel (Crève-Cœur); J. W. Will.

Game.—*Black or Brown Red.*—*Cock.*—1 and Cup, C. W. Brierley. 2, H. M. Julian, Hull. 3, S. Beighton, Farnafield, Southwell (Black Red). *hc*, J. H. Wilson. *c*, T. Mason, Green Ayre, Lancaster. *Cockerel.*—1, 3, & Cup, Master W. Fletcher (Black Red). 2, S. Beighton (Black Red). *hc*, R. H. Campbell, Greenock (Brown Red); W. Hastwell, Whitehaven; J. W. Will. *Any other Variety.*—*Cock or Cockerel.*—1, Master W. Fletcher, Stonecrough (Duckwing). 2, H. M. Julian (Duckwing). 3, J. Sunderland, Halifax (Pile). *hc*, E. Woodburn, Ulverston; J. H. Wilson (Duckwing). *Hen.*—1 and 2, C. W. Brierley. 3, G. R. Smith, Scarborough. *hc*, T. Mason. *Pullet*—1, 2, and Cup, C. W. Brierley. 3, W. Grice, Bootle. *hc*, W. Boulton, Dalton; Master W. Fletcher; J. Masbiter, Ulverston (2); J. W. Will. *c*, J. H. Wilson.

Hamburghs. — *Golden-spangled.* — 1 and Cup, H. Beldon. 2, J. Buckley, Taunton, Ashton-under-Lyne. 3, J. Rollinson. *hc*, J. Rollinson; J. Ogden, Hollinwood; J. W. Will. *Silver-spangled.*—1, 2, and *hc*, Ashton & Booth, Mottram. 3, H. Beldon. *Golden-pencilled.*—1, W. R. Park. 2, H. Beldon. 3, C. Moore, Poulton-le-Fylde. *hc*, J. W. Will. *Silver-pencilled.*—1 and 3, H. Pickles, jun., Earby. 2, W. M. Mann, Kendal. *hc*, H. Beldon.

Game Bantams.—*Black Reds.*—*Cock.*—1, G. Hall, Kendal. 2, J. Masbiter. 3, E. Hudson, Ulverston. *hc*, J. R. Robinson, Sunderland; H. H. Thompson, Sunderland; J. T. Hudson. *Hens or Pullets.*—1, G. Hall. 2, J. W. Morris, Rochdale. 3, G. Todd, Sunderland. *hc*, G. Hall; R. Brownlie. *Any other variety except Black Reds.*—1, 2, and Cup, H. J. Nicholson, Holborn Hill, Cumberland (Duckwing). 3, W. Adams, Ipswich (Brown Red). *hc*, J. Sichel (Piles); W. Scott, Sedburgh (Duckwing); J. W. Brockbank, Kirksanton (Duckwing); Bellingham & Gill, Barnley (Piles). *c*, J. Archibald, Earlstown (Brown Red).

Bantams.—1, M. Leno, Markyate Street. 2, Mrs. F. S. Arkwright. 3, Miss B. Parker. *hc*, H. Beldon; J. Sichel; S. & R. Ashton, Mottram.

Ducks.—*Aylesbury.*—1, E. Leech, Rochdale. 2, J. K. Fowler. 3, J. Robinson. *hc*, E. Fearon; Mrs. Birkett; S. H. Stott; J. K. Fowler. *Rouen.*—1 and Cup, S. H. Stott. 2, Gunson & Jefferson. 3, W. G. Mulligan. *hc*, A. Dickinson, Distington; J. Thompson, Chocketford; E. G. Jones; W. Robinson. *c*, L. Patton; J. Fox; J. K. Fowler. *Black East Indian.*—1 and 2, S. Burn, Whithy. 3, Rev. W. Sergeantson, Acton Burnell. *Any other Variety.*—1, C. W. Brierley. 2, M. Leno (Mandarins). 3, H. B. Smith, Broughton (Shiels). *hc*, S. & R. Ashton (Carolina); S. Burn (Mandarins); H. B. Smith (Mandarins and Carolina); S. H. Stott; M. Leno (Carolina); J. Watts; T. Musgrave (Mallards).

Turkeys (Any variety).—1, E. Leech. 2, S. Sherwen. *hc*, W. Grice.

Geese (Any variety).—1, Rev. G. Hustler, Stillingfleet Vicarage. 2, S. H. Stott (Toulouse). *hc*, E. Leech. *c*, J. Logan.

Any other Variety except Bantams.—1, H. Beldon. 2, J. P. Fawcett, Whitby. 3, W. Harvey, Sheffield. *hc*, M. Nicholls, Peel, Isle of Man; J. Watts.

Selling Class.—1, R. D. Holt. 2, H. Beldon. 3, J. Cowman. 4, E. Fearon. 5, R. Smalley. *hc*, W. Cook, Hale, Carnforth (Buff Cochins); E. Fearon (White and Buff Cochins, and Black Spanish); H. Yardley; Gunson & Jefferson (2); H. Beldon; R. D. Holt (Dorkings) (2); J. H. Wilson (White Cochins and Game); E. G. Jones (Rouen Ducks); Mrs. Birkett (Buff Cochins); C. Mc.Clellan (White Cochins); W. Boulton (Brown Red Game); J. Robinson; J. Cowman (Brahmas); T. Mason (Game); J. Wilson (Black Red Game); J. Watts; J. W. Will; Mrs. F. S. Arkwright (Black Red Game).

PIGEONS.

Carriers.—1, J. & W. Towerson, Egremont. 2, E. Horner, Harewood. *hc*, H. Yardley; E. Horner; J. & W. Towerson.

Pouters.—1 and Cup for best pen of Pigeons, J. & W. Towerson. 2, E. Horner. *hc*, E. Horner; G. Sturgess, Leicester; W. Harvey.

Tumblers.—*Almond.*—1, J. Ford, Monkwell Street, London. 2, W. Harvey. *hc*, H. Yardley; E. Horner (2); J. Ford; J. & W. Towerson. *Any other Variety.*—1, J. Fielding, jun., Rochdale. 2, J. Ford. *hc*, G. Sturgess (2).

Jacobins.—1, J. & W. Towerson. 2, W. G. Easten, Hull. *hc*, T. W. Kilburn, Bishop Auckland; J. W. Edge, Birmingham; J. & W. Towerson.

Trumpeters.—1 and 2, E. Horner. *hc*, H. Beldon.

Barbs.—1 and *c*, H. Yardley. 2, J. & W. Towerson. *hc*, W. Jackson; J. Fielding, jun.; G. Goore; J. & W. Towerson.

Turbits.—1, W. G. Easten. 2, J. & W. Towerson. *hc*, H. Yardley; E. Horner. T. W. Kilburn; J. & W. Towerson.

Owls.—1, H. Beldon. 2, J. & W. Towerson. *hc*, J. Armstrong, Workington; T. W. Kilburn; J. & W. Towerson.

Fantails.—1, E. Horner. 2, H. Beldon. *hc*, H. Yardley; J. W. Edge.

Dragoons.—1, H. Beldon. 2, J. W. Edge. *hc*, W. H. Mitchell, Moseley, Birmingham; J. Watts; G. South, New Bond Street, London; W. Harvey.

Any other Variety.—1, H. Beldon. 2, W. Jackson. *hc*, H. Yardley; T. W. Kilburn; J. Watts; J. Fielding, jun.; W. Harvey.

Selling Class.—1, J. W. Towerson. 2, W. R. & H. O. Blenkinsop. *hc*, J. and W. Towerson; Mrs. F. S. Arkwright (Antwerp and Dragoons); J. W. Edge. *c*, H. Beldon.

Cup for the most successful exhibitor.—Messrs. J. & W. Towerson.

Canaries.—*Belgian* (Yellow).—1, J. N. Harrison, Belper. 2 and *c*, W. Robinson, Workington. *hc*, D. Tweedie, Whitehaven. (Buff).—1, J. N. Harrison. 2, P. Watson, Whitehaven. *hc*, S. Sherwen. *Mules* (Buff).—1, R. Hawman, Middlesbrough. 2, R. Carr, Carlisle. *hc*, J. Harkness, Whitehaven. *Piebald* (Yellow or Buff).—1, J. N. Harrison. 2, Stevens & Burton, Middlesbrough. *hc*, R. Carr. *c*, R. Hawman. *Lizards* (Gold or Silver-spangled).—1, R. Hawman. 2 and *c*, Stevens & Burton. *hc*, J. N. Harrison.

Judges.—*Poultry:* Mr. R. Teehay, Fulwood, Preston; *Pigeons, Ducks, Geese, and Turkeys:* Mr. J. Dixon, North Park, Bradford; *Canaries:* Mr. A. Benson, Whitehaven.

CRYSTAL PALACE BIRD SHOW.

For the information of those readers of the Journal who may be looking for some report of the Show which is now open and will remain so till Friday, I pen a few hasty notes while waiting for the train, promising to supplement them at length next week. Taking the Show as a whole, it is one of great merit. The Clear Jonques and Mealies are in many instances, and notably so in the case of the winning birds, of extraordinary merit. Mr. Walter is once more at the top of the tree in Jonques with a splendid bird, and Mr. Mackley second with a remarkable specimen, which ought to have been disqualified, being Ticked, and consequently entered in a wrong class. The third is a fair bird, but I think I could name more than one which I prefer. Among the unmentioned division stands Mr. Judd with six excellent Jonques.

The Clear Buffs constitute a superior class, the first four being rare birds, full of colour and bloom. Mr. Mackley shows two which are equal third, and one of them is about as good as anything in the class. Each was soon claimed at the low price of £1. No. 73 is a good bird, and so are 68, 97, and 81.

In the Evenly-marked Jonques Mr. Hawman's bird stands unapproached. Adams & Athersuch are second with a remarkably neat hen, and one of the equal thirds also is a hen, the third honour being shared by Moors & Wynn and Smith & Preen, a Coventry firm. Nos. 114, 118, and 120 well merit their cards. Walter, Adams & Co., and Moore & Wynn share the honours in the Even-marked Buffs with very fine birds in close company.

The Ticked Belgians are, many of them, superb. Nos. 175 (Mackley), 184 (Moore & Wynn), and 177 (Bemrose & Orme), among the Jonques are enough to make anyone's mouth water and create a longing for that jonque mineral, of which a liberal supply is required to enable one to become their purchaser.

In Ticked Mealies Mr. Havers is first with 230, all quality: but it is a very near thing between it and the second (No. 242, Walter). Messrs. Toon & Cleaver are third with a very rich bird, and all the mentioned specimens are meritorious.

The crests are a great improvement on last year, and the Buffs well deserve the comment of the Judges, which is appended to the return list, "A splendid class." There are some magnificent birds among them. No. 283, first Buff (Mackley), is full of good Norwich points, and with but few exceptions most of the birds are well worth a careful inspection.—W. A. Blakston.

Owing to the excessive dryness of last spring great difficulty was experienced in rearing young birds, added to which the importations from Germany and France have, during the last six months, entirely ceased, and fears were entertained as to the success of a bird Show under such disadvantages; but it is evident that no apprehensions of the kind need have been entertained. The entries are nearly if not quite as numerous as on former occasions, while the quality, for which the show of last year was so famous, is maintained in the present instance. Canaries are always strong, and especially the Norwich birds. Next come the Belgians; although there may be many points of interest about them which render them attractive to exhibitors, yet they cannot either as to appearance or symmetry of form be compared to the Norwich classes. Mules are always good, and so are the London Fancy.

The following are the number of birds exhibited :—

	No. of birds.		No. of birds.
Norwich Classes	327	Brought forward	629
Belgians	35	Aviaries (14)	84
London Fancy	32	British Birds	147
Other Classes	148	Foreign Birds	19
Mules	87	Miscellaneous	187
Carried forward	629	Total	1146

NORWICH (Clear Yellow).—1, W. Walter, Winchester. 2, R. Mackley, Norwich. 3, W. Cooke, Norwich. *vhc*, R. Mackley; T. Irons, Northampton; Cockle & Watson; W. Walter. *hc*, Bemrose & Orme, Derby; S. Bunting, Derby; Smith & Preen; T. Fenn, Ipswich; Adams & Athersuch, Spon End, Coventry. *c*, R. Mackley (5); S. Bunting; Moore & Wynn, Northampton (2); W. Havers, Norwich; J. Judd, Newington Butts (2); T. Mann, Camberwell.

NORWICH (Clear Buff).—1, Toon & Cleaver, Kettering. 2, W. Walter. Equal 3, R. Mackley (2). *vhc*, Bemrose & Orme; S. Bunting; W. Walter. *hc*, Moore and Wynn; Bexson & Bennett, Derby; Adams & Athersuch; W. Cooke; J. Doel, Stonehouse, Devon. *c*, Bemrose & Orme (2); Moore & Wynn; Adams and Athersuch (2).

NORWICH (Marked or Variegated Yellow).—1, R. Hawman, Middlesbrough. 2, Adams & Athersuch. Equal 3, Moore & Wynn; Smith & Preen. *vhc*, S. Bunting; Smith & Preen; J. Judd. *hc*, W. Havers; Bexson & Bennett. *c*, J. G. Stephenson, Bishop's Cleeve, Cheltenham; T. Irons; Moore & Wynn; W. Havers; Bexson & Bennett; T. Fenn.

NORWICH (Marked or Variegated Buff).—1, W. Walter. 2, Adams & Athersuch. 3, Moore & Wynn. *vhc*, R. Mackley; Moore & Wynn (3); W. Walter. *hc*, R. Mackley; Bemrose & Orme; S. Bunting; Bexson & Bennett; T. Fenn; J. Judd. *c*, G. Gayton, Northampton; T. Fenn; J. Judd; J. Marshall, Derby; W. Cooke.

NORWICH (Ticked or Unevenly Marked Yellow).—1, R. Mackley. 2, Moore and Wynn. 3, Bemrose & Orme. *vhc*, Smith & Preen; Cockle & Watson; W. Walter; T. Mann. *hc*, R. Mackley; S. Bunting; Smith & Preen; Bexson and Bennett; T. Fenn; T. Newmarch, Crystal Palace. *c*, R. Mackley; W. Walter; P. Flexney, London; E. W. Lulham (2).

NORWICH (Ticked or Unevenly Marked Buff).—1, W. Havers. 2, W. Walter. 3, Toon & Cleaver. *vhc*, Bemrose & Orme; Moore & Wynn; W. Walter; Adams & Athersuch. *hc*, R. Mackley (3); Bemrose & Orme; Cockle & Watson, Terrington St. John; Bexson & Bennett; W. Walter. *c*, S. Bunting; Moore and Wynn; W. Havers; T. Newmarch; E. W. Lulham, Brighton.

NORWICH (Crested Yellow).—1, T. Fenn. 2, Toon & Cleaver. 3, Bemrose and Orme. *vhc*, T. Irons (2); Moore & Wynn; R. Hawman. *hc*, H. Apted, Worthing; Moore & Wynn (2); T. Fenn; G. Cox, Northampton. *c*, Bexson and Bennett; T. Fenn; W. Walter; J. Tarr, London.

NORWICH (Crested Buff).—1, R. Mackley. 2 and 3, Moore & Wynn. *vhc*, R. Mackley; Moore & Wynn (2); W. Havers; H. N. Fosbrooke, Hatfield, Doncaster. *hc*, Moore & Wynn; Smith & Preen; Bexson & Bennett. *c*, R. Mackley; H. Apted; Bexson & Bennett; J. Judd; W. Walter; J. Goode, Leicester.

BELGIAN (Clear Yellow).—1, J. N. Harrison, Belper. 2, J. Poole, Sutton-in-Ashfield. 3, J. Doel. *vhc*, C. Carver, Lamport; J. Close, Derby; J. Doel. *hc*, W. Walter.

BELGIAN (Clear Buff).—1, J. Doel. 2, J. Poole. 3, C. Carver. *vhc*, G. Tuckwood, Nottingham; W. Walter. *hc*, W. Harley; J. Doel.

BELGIAN (Variegated or Ticked Yellow).—1 and 2 J. Doel.

BELGIAN (Variegated or Ticked Buff).—1, Withheld. 2, W. Harley.

LONDON FANCY (Jonque).—1 and *hc*, W. Brodrick. 2, 3, *vhc*, and *hc*, J. Waller. *c*, T. Clark, Sutton, Surrey.

LONDON FANCY (Mealy).—1, *vhc*, and *hc*, J. Waller. 2 and 3, W. Brodrick. *c*, T. Clark.

LIZARD (Golden-spangled).—1, H. Ashton, Polefield Hall, Prestwich. 2, J. Judd. 3, T. W. W. Fairbrass, Canterbury. *vhc*, R. Mackley; G. Tuckwood (2). *hc*, G. Harrison; J. Poole; T. W. W. Fairbrass; W. Dann, Nottingham; T. Clark. *c*, J. N. Harrison; J. Poole; T. W. W. Fairbrass; T. Clark.

LIZARD (Silver-spangled).—1, H. Ashton. 2, R. Mackley. 3, S. Bunting. *vhc*, J. Poole; Adams & Athersuch; H. Ashton. *hc*, J. N. Harrison; G. Harrison. *c*, G. Harrison.

CINNAMON (Jonque).—1, T. Irons. 2, S. Tomes, Northampton. *vhc*, G. Gayton, Northampton; H. J. Ims, Bloomsbury; S. Tomes. *hc*, T. Irons; J. Spence, New Hendon, Sunderland; C. W. Hooke, London; Moore & Wynn. *c*, S. Bunting; T. Irons.

CINNAMON (Buff).—1, J. Waller, London. 2, W. Gamble. *vhc*, T. Irons; H. Apted; W. Gamble. *hc*, Moore & Wynn (2). *c*, T. Irons; W. Walter (2); J. H. Hadland.

CINNAMON (Marked or Variegated).—1, Bemrose & Orme. 2, S. Tomes. *vhc*, H. Apted. *hc*, Moore & Wynn; J. H. Hadland, Wallington. *c*, P. Rawnsley, Ledget Green, Bradford; H. Apted; Moore & Wynn.

ANY OTHER VARIETY.—1, H. Ashton (Manchester Coppy). 2, E. Stansfield, Bradford. 3, J. Baxter, Newcastle (Glasgow Fancy). *vhc*, J. Judd (Manchester Crested Coppy and Manchester Coppy). *hc*, P. Rawnsley; Moore & Wynn (2) (Crested Cinnamon); R. Hawman (Yorkshire). *c*, T. Newmarch.

GOLDFINCH MULE (Yellow).—1, J. Doel.

GOLDFINCH MULE (Buff).—1, H. Ashton. 2 and *hc*, J. Doel.

GOLDFINCH MULE (Variegated Yellow).—1, H. Ashton. 2 and 3, J. Doel. *vhc*, W. B. Bailey, Purfleet; H. Ashton (2); J. Doel. *hc*, H. J. Ims.

GOLDFINCH MULE (Variegated Buff).—1, Fairclough & Howe, Middlesbrough. 2, J. Doel. 3, J. Baxter. *vhc*, H. J. Ims; W. B. Bailey; J. Doel (3). *hc*, S. Bunting; H. J. Ims; H. Ashton. *c*, Rev. V. Ward, Hythe; H. J. Ims.

GOLDFINCH MULE (Dark Jonque).—1, E. Stansfield. 2, R. Hawman. *vhc*, S. Bunting; Moore & Wynn (3). *hc*, J. Cooper, Penge. *c*, T. Willsher, Chichester; T. E. Fosbrooke, Carlton Hills, Leeds; W. B. Bailey.

GOLDFINCH MULE (Dark Mealy).—1, W. L. Chapman. 2, W. Smith. *hc*, E. Stansfield; J. Cooper; W. Dann, Nottingham.

LINNET MULE.—1 and *vhc*, J. Spence. 2, H. Ashton. *c*, W. Few, Forest Hill.

MULES (Any other variety).—1, W. Yeoman, Leeds (Bullfinch and Canary Mule). 2, E. Stansfield (Bullfinch and Goldfinch Mule). 3, H. Ashton (Linnet and Bullfinch Mule). *vhc*, E. Stansfield (Bullfinch and Goldfinch Mule); T. Irons (Black and White Goldfinch Mule); J. F. Cookson, Preston (Goldfinch and Greenfinch Mule); W. Verner, Brighton (Linnet and Bullfinch Mule); H. Ashton (Goldfinch and Bullfinch Mule). *c*, G. Locke (Linnet and Goldfinch Mule).

NORWICH (Cage of Six, irrespective of Colour).—1, 2, and 3, W. Walter. *vhc*, Moore & Wynn; T. Fenn; W. Cooke.

BELGIAN (Cage of Six, irrespective of Colour).—1, Withheld. 2, C. Carver.

LIZARDS (Cage of Six, irrespective of Colour).—1, H. Ashton. 2, Clark and Hooke.

GOLDFINCH MULES (Cage of Six).—1, J. Doel. 2, H. Ashton. 3, E. Stansfield. *vhc*, J. Doel. *hc*, H. J. Ims.

MISCELLANEOUS.—Prize, J. Baxter (Black Goldfinch Mule).

BRITISH BIRDS.

BULLFINCH.—Prize, R. Mackley. *hc*, A. Webster, jun., Kirkstall, Leeds; J. Judd. *c*, Moore & Wynn; W. Walter; T. Willsher.

GOLDFINCH.—Prize, J. Doel. *vhc*, Moore & Wynn. *hc*, G. Cox; J. Doel. *c*, Fairclough & Howe; J. Spence.

LINNET.—Prize, J. Baxter. *hc*, H. Green. *c*, G. T. Harrison; Fairclough and Howe; J. Baxter.

SKYLARK.—Prize and *hc*, J. S. Benton, Rochester. *c*, J. Judd.

WOODLARK.—Prize, W. Walter.

ROBIN.—Prize, G. Cox. *c*, W. J. Walling, London.

BLACKBIRD.—Prize, Miss M. A. Robinson, Sydenham. *hc*, J. Judd. *c*, W. Walter.

SONG THRUSH.—Prize, J. S. Benton. *hc*, A. Raven, Norwood. *c*, J. W. Smyth, London.

STARLING.—Prize, J. Judd.

ANY OTHER VARIETY OF BRITISH BIRDS.—Prize, T. Newmarch (Mealy Bullfinch). Prize, W. Walter (Dove-coloured Blackbird). Prize, G. Cox (Yellow-hammer). Prize, J. W. Gessey (Chaffinch). *c*, A. Webster, jun. (Bramblefinch); H. Ashton (Cinnamon Goldfinch).

BIRDS OF PASSAGE AND MIGRATORY BIRDS.

BLACKCAP.—Prize and *hc*, A. Rettich, Peckham.

SISKIN OR ABERDEVINE.—Prize, R. Mackley. *hc*, J. Baxter; T. Willsher. *c*, J. Judd.

ANY OTHER VARIETY.—Prize withheld. *hc*, W. Walter (Tree Sparrow).

FOREIGN BIRDS.

COCKATOO (Lemon or Orange-crested).—1 and 2, M. George, London.

COCKATOO (Leadbeater or Rose-breasted).—1, Mrs. Astley, Prince's Risborough. 2, T. Newmarch. *vhc*, W. B. Bailey; J. Judd.

COCKATOO (Any other variety).—Prize, W. B. Bailey (Slender-billed).

PARROTS (Grey).—1, J. G. Wingrove, Purfleet. 2, H. Webster, London. *hc*, Mrs. Ramsay, Brixton. *c*, J. Judd.

PARROTS (Green or any other variety of large, except Grey).—1, J. Judd (Green Parrot). Equal 2, W. B. Bailey. Equal 2, and 3, T. Newmarch (Bulla Bulla and Mealy Rosella). *vhc*, H. Jenner, Camberwell (Green Parrot); W. B. Bailey (Bulla Bulla and Rock Peblar). *hc*, J. Battershill, London (Rosella).

LOVE BIRDS.—Prize, W. B. Bailey. *vhc*, W. Walter. *hc*, J. Judd.

PARAKEETS (Australian Grass).—Prize and *vhc*, J. Judd. *hc*, T. Newmarch.

PARAKEETS (Ring-necked or Bengal).—Prize, T. Newmarch. *vhc*, T. Newmarch; P. L. Heisch, Chelsea. *c*, W. Underwood.

SMALL PARROTS OR PARAKEETS (Any other variety).—Prize, W. B. Bailey (Blue Mountain Lorykeet). *hc*, J. Judd (Turquoisenes).

COCKETEALS.—Prize, T. Newmarch. *vhc*, J. Judd. *hc*, W. Walter.

SPARROWS.—*Diamond.*—Prize, W. B. Baily. *vhc*, T. Newmarch. *hc*, J. Judd. *c*, T. Newmarch. *Java.*—Prize, J. Judd.

ANY VARIETY OF WAX BILLS.—Prize, J. Judd. *vhc*, W. B. Bailey.

CARDINAL.—Prize, W. B. Bailey. *c*, E. Sweeting, Sydenham.

ANY OTHER VARIETY OF FOREIGN BIRDS.—1, T. Newmarch (Java Mina). 2, W. Walter (Madagascar). 3, J, Doel (Saffron Finch). Extra, W. B. Bailey (Collection of Foreign Birds). *vhc*, W. B. Baily (Yellow Weavers); T. Newmarch (Nonpareil); C. A. Stein (Brouze Manaskins). *hc*, W. B. Bailey (2) (Parson Finch and Collection of Foreign Waxbills); W. Walter (Saffron Finch).

JUDGES.—*Canaries:* Mr. Barnesby, Mr. Moore, and Mr. Wilmore. *British and Foreign Birds:* Mr. John Jenner Weir, F.L.S., and Mr. Harrison Weir, F.R.H.S., assisted by Mr. F. W. Wilson.

PRIZE LISTS FOR CARRIER PIGEONS.

I HAVE no doubt committees often class Carriers in pairs, believing that they cannot afford to give prizes for two classes; this is a great mistake—two classes pay better than one, for the very reason that Colonel Hassard gives—viz., "that, as a rule, no fancier breeds from two Blacks or two Duns," consequently they are very seldom paired fit for exhibition. It is sometimes very difficult to mate Carriers as you wish them to breed (I think they are the worst of any Pigeons in this respect), and fanciers cannot afford to undo what has given them so much trouble, and in addition risk a battle with two valuable birds that carry such formidable weapons as their beaks. Last summer a large cock I had came in contact with a very promising young hen that was strange to him, and he scalped her as cleanly as any American Indian could have done, and had I not entered the loft in time would have destroyed her eyes; as it was, she could not see with one eye for weeks afterwards.

In consequence of these difficulties all shows where Carriers are classed in pairs suffer both in quantity and quality; and more especially after this date, when the birds are mated for breeding they will scarcely get a class worth notice, except one or two pens belonging to persons who buy birds to exhibit and not to breed.

As facts are convincing, I give the results of Carrier entries at a few shows held during the past season.

		No. of Entries.	Entry Fees. £	s.	d.	Prizes given. £	s.	d.
Oakham	shewn in pairs	4	0	14	0	1	10	0
Ipswich	" "	9	1	7	0	1	2	6
Leeds	" "	10	1	10	0	1	10	0
Long Sutton	single birds	58	8	14	0	8	5	0
Lowestoft	" "	41	4	2	0	3	0	0

Now, as the great desire is to get a good show as well as one that will meet expenses, it is evident that single birds answer the two purposes best, for while Oakham, Ipswich, and Leeds had only entries numbering respectively four, nine, and ten, Long Sutton and Lowestoft obtained fifty-eight and forty-one entries, and the entry fees pay the prize money—an important point for committees to study. A class for young Carriers pays best of all. London, Long Sutton, and Lowestoft offered prizes for young Carriers at their last shows, and received good entries—London thirty pens, Long Sutton twenty-two, and Lowestoft fourteen. Ipswich also, although the birds were shown in pairs, was confined to birds of 1870, and it shows a better result financially than either Oakham or Leeds.

I believe Carrier-fanciers are increasing, and I think I am not wrong when I say there are more good birds in the kingdom than ever, and if committees will only properly arrange their Carrier classes by giving prizes for cocks and hens separately, and a class for birds under one year (single bird, either

cock or hen), they will have good birds, and in such numbers as will pay them.—L. Wren, *Lowestoft.*

IS THE RABBIT FANCY ON THE DECLINE?

Mr. Gooding's able reply goes to strengthen my remarks as to the great scarcity of Lop-ears owing to their being so difficult to breed, and on account of their greater value they ought to occupy the front rank in a Rabbit show. The very reason that we had so many entries of fancy Rabbits at York was their being so common, so easily bred, and of so little value. The pair of Angoras that won the first honours at the York Show belonged to two poor lads who stand in our market with a few Pigeons and common Rabbits. The forty-five Lop-eared Rabbits entered at our show belong to thirty good Rabbit fanciers whose names are household words amongst us; but out of the forty-five fancy Rabbits entered, there were not a dozen good fanciers' names, the majority belonging to lads whose names are unknown amongst the fancy. The fancy-Rabbit men are able to make a dozen or more entries in a show, for such Rabbits are so easily procured and breed so fast that their owners are able to enter largely; but the Lop-eared fanciers have to be content by entering from three to six or more, generally one. There is no comparison between the two in value. I had at one time ten Rabbits, which I valued at £100, and I could have sold them for that sum, and I very much question if there is a fancy variety dealer in the country who has a stock to amount to anything near that sum, and who can count his stock by from forty to sixty.

I am of opinion that, taking the country throughout, the fanciers of Rabbits are on the decline. I include fanciers of all varieties. I should delight to see the day when Rabbits were placed on the same footing as the other fancies which compose our shows. It cannot but be admitted that at present, with committees, Rabbits are either left out altogether or very meagrely represented. Can we expect, so long as this neglect continues, that the fanciers of Rabbits will increase?

The question, then, arises, How are Rabbits to be raised to an equal position with poultry and Pigeons? I think that it can only be done by fanciers sinking all differences and jealousies, and uniting into an association that will recommend the fancy to the public at large, and to committees of poultry shows in particular. Since throwing out a hint about the formation of a United Kingdom Rabbit Club, I have had letters from many influential fanciers wishing such a Club to be formed and carried out. My idea is for the Club to be formed upon the following basis—

That it be composed of Rabbit fanciers, to become members by subscribing 1*s.* annually. That a city or town be chosen as the head quarters of the Club. That a committee be chosen out of every town at the rate of one committeeman to every four members. That an unpaid secretary be appointed to do the work well for the love of the fancy. That the secretary keep a register not only of members, but of every known fancier in the kingdom. That the members keep the secretary well supplied with information—anything that is interesting to the fanciers. That the secretary correspond with every poultry-show secretary prior to the schedule being issued, to suggest classes, and, where no Rabbits have been exhibited, to use his influence to have such classes established; also to keep up a continual correspondence with secretaries of local clubs. The secretary to be a well-known fancier, one to whom any new beginner can apply for information and advice as to the management of Rabbits.

I would expend any surplus funds by holding a "grand Rabbit show" successively in different towns.

By the formation of such a Club, if it were well worked, I believe the fancy would increase and revive, also a tone would be given to it which it does not at present possess. If this meets the approval of all fanciers I am willing to set the Club going, and when established the committee can appoint a secretary.—M. Millington, *York.*

EXAMINING STOCKS.

The period is approaching when scientific apiarians will be taking advantage of a fine day for the purpose of inspecting their hives, and ascertaining how they have fared during the late protracted frost, which, with only one short intermission, extended over seven weeks. Some that were weak and not well supplied with stores will be found to have succumbed to the severity of the season; others that were strong and well provisioned, and prepared for winter's storms, will be seen to have sustained little or no injury. We should profit by experience—our very errors are good teachers—and when we find anything in our practice that has been faulty and followed by evil consequences, our wisdom is not to repeat our mistakes.

The desire to know the condition of our hives is liable to be gratified at some expense when proper precautions are not taken, as I learned to my cost nearly twelve months ago. About the beginning of March the weather happened to be cold and ungenial, but the 16th was calm; and although no bees were going abroad I concluded it would be quite safe to make an examination of one of my stocks, and that, as the temperature was over 40°, no harm could come to the brood from a short exposure of the frames in the open air. This conviction, as the result showed, was well founded, but it did not occur to me that the carrying out of my intended inspection might be the occasion of serious loss to an adjoining stock not more than 3 feet removed—a distance, by the way, far too small for the separation of hives, seeing they ought to be placed as far apart as circumstances will permit. Without, therefore, feeling any concern for the safety of my other stocks, I proceeded at once to remove the crown board and elevate the frames; but whilst holding them up to view a number of bees flew off and soared into the air. These fugitives, I imagined, would return by their accustomed entrance to their homes, but instead of doing so they seemed bewildered, and several went directly into the hive located nearest their own. This showed me the propriety of suspending operations, so after adjusting the frames I shut up the hive as quickly as possible. I need hardly say that I was apprehensive of consequences, but as the stock receiving the stray bees remained perfectly quiet throughout the remainder of the afternoon, my equanimity was not much disturbed.

I felt, however, that an error had been committed, and next day, when reflecting on the matter, I thought it would be prudent to make an investigation, and see whether the stragglers which had entered a strange dwelling without opposition were keeping the peace in their new home. Accordingly, after employing precautions that had been neglected on the previous day, I commenced operations in the usual manner. A glance showed that all was not right. The inhabitants evidently were in a state of commotion, and that peculiar sound could be heard which is emitted whenever a queen is encased. I had not to search long before I discovered that my worst fears were realised, but the rescue intended on my part came too late. The queen was found in the very heart of a compact ball of regicides and hopelessly injured, her body being already rigid and shrivelled. Her deliverance and death was almost simultaneous. Now, if a friend having a spare queen had not come to my aid, this stock, losing its sovereign so early as the middle of March, must have been utterly ruined, and it is to put others on their guard that I am induced to state my experience.

Bees, as is well known to observers, go out from their habitations after long confinement in the same manner as from a young colony. They do not fly off directly, but make two or three circles, so as to enable them to become acquainted with the place they have left and avoid making any mistake on their return; consequently if they have been kept within-doors for some time they should have an opportunity of reconnoitering their entrances before any attempt is made to open up their hives, otherwise, as in the case mentioned, they may take advantage of the situation and fly off from the frames, and ignorantly or stupidly enter the homes of their neighbours for their own. But when a stock is to be examined early in spring, all danger may be avoided by shutting up the entrances of hives which are near to it with perforated zinc, or, what is more convenient, wetting them with carbolic acid. In the one case stragglers cannot enter a wrong dwelling, and in the other they dare not. As the life of the queen is the most valuable life in the hive and essential to its existence, nothing should be done which is calculated to put her precious person in peril. Bee-masters, then, would do well to beware in early spring, and before the season is advanced, of a practice which is sometimes resorted to for the purpose of strengthening a weak colony—viz., that of putting it on the stance of a strong one. By making two stocks exchange their stances at an improper season both stocks may be lost through their queens being imprisoned and killed.—R. S.

OUR LETTER BOX.

Books (*H. Browne*).—"Poultry Book for the Many," for seven postage stamps. "Poultry-keeper's Manual," free by post from our office for sixty-four postage stamps.

Keeping Poultry as an Employment (*H. H.*).—Your question is a difficult one to answer. Few men can live by poultry alone. To keep it profitably requires a thorough knowledge of the subject, and, trifling though it appear, there is no royal road to it. All the theory may be learned from books, but much can be only gained from experience. In poultry, as in everything else, that must be bought. If your friend is about to breed and send the ordinary poultry, and fatten it only as it is fattened in Ireland, we should advise him to send it to Liverpool; if he means to make it good enough for the London market, let him send it there. He must choose his season. In the hot weather much pains and care are required in fattening, fasting, killing, and packing to enable it to reach its destination in a fit state to realise a good price. Advantage must also be taken of the time of year. Poultry is most valuable in London in April, May, and June. Irish chickens well killed will make good prices during those months, but they must be chickens in age as well as name. It would be necessary he should choose a good breed, as the ordinary Irish chickens with black, blue, and yellow legs eat as much

as better-bred birds, and do not make as much. We do not think he would be wise to give up a permanent employment for poultry-keeping, but we would advise him to begin with a few. He will gain experience, and will see how far it will answer. No man in the ordinary trade can breed enough to live by it, he must collect from the surrounding country. He will have to buy them in lean and to fatten them. This renders it necessary to keep a horse and cart, and a cow. Good poultry cannot be made without milk. If your friend could get into relation with some man at the nearest seaport and sell to him, it would probably be the best thing he can do, as it will reduce his venture to a certainty. We believe poultry will be found a valuable adjunct; but knowing as much as we do on the subject, we do not advise anyone to give up a permanent employment to take to poultry.

Silver-spangled Hamburghs' Combs (*C. M. M.*).—It is most difficult to breed prize cocks and hens from the same stock. It generally takes two yards to do it. The hollows in the combs are serious defects, and would disqualify from a first prize with any really first-rate judge. We would not breed from a cock with such a defect.

Breeding Black Hamburghs (*Baron*).—They are bred in all the ways you mention. We like a Spanish hen and a dark Yorkshire black-breasted Golden-spangled Hamburgh cock. In whatever way you breed them, you have to breed out one point and increase another afterwards.

Crooked-breasted Cock (*J. S. Z.*).—You should tell us the breed of your bird. In a Game cock we would not suffer a deviation from the straight line in the breastbone. In birds of weight we should not be so particular, but if we had a perfectly straight-breasted one we would discard the crooked were it ever so trifling.

Fowls for Laying (*A Subscriber*).—Crêve-Cœur, Houdan, or Spanish; we think the first.

Breed of Hen (*G. E. A.*).—We have little doubt that the hen in question is a Crêve-Cœur. Your description tallies with that of the breed. Rub the bare place on the neck with compound sulphur ointment.

Silver-pencilled Hamburghs (*A Subscriber*).—There are two pencillings to be avoided; one so faint as to be indistinct, the other so very dark and pervading, that it forms blotches; this is called mossy. Hamburghs should not be thick and squat, but rather taper in shape and form. The comb should be a well-defined double comb with a pike at the back turning upwards. It should be full of points, have no hollow in the centre, and be fixed firmly on the head, inclining to neither side. No other comb is admissible. A Guinea Fowl has no comb, it has a knob. Choose the birds that are nearest to our description.

Fowls Losing Head and Neck Feathers (*F. T., Exon*).—It is probable your fowls peck each other's feathers. Rub the bare spots with compound sulphur ointment. It is probable as the weather changes, if your fowls have a grass run, they will discontinue the practice. If they have not, you must supply them with sods of growing grass cut with plenty of mould, and with green stuff of some kind. Generally when fowls eat each other's feathers, it is because they lack something necessary to their well-being, and feathers are a substitute.

Hen Dropping her Eggs (*C. M. S.*).—The hen drops her eggs because she is out of condition. You can prevent her dropping them by removing the perches, or you can save the eggs by putting hay or sawdust under the perches. You do not overfeed, but we advise you to substitute barley-meal for barley, and whole maize for ground. We do not think you have any right to complain of the laying. From three hens in fifteen days you have twenty-two eggs in very bad weather; each hen laying every alternate day would produce the number, and that is an excellent average. If you were to add those dropped from the perch, and thereby lost, we believe you have done better than your neighbours.

Hardiness of Hamburghs (*Henricus*).—We believe the Golden Hamburgh of both varieties to be hardier than the Silver, and the Spangled hardier than the Pencilled. Birds should not be sent out in a deplorable state.

Shooting Stray Fowls (*Ridiculus Mus*).—Your neighbour will act illegally if he shoots your fowls which invade his garden, but he may sue you in the County Court for the trespass.

Swindlers (*G. G.*).—The parties you name at Walham may be swindlers, and we will communicate with the police. Buyers and sellers of poultry need never be swindled if they would adopt the caution we have so frequently urged.

Portsmouth Show (*W. T. S.*).—The Secretary ought to return your money if he did not send you a catalogue. The post office may be to blame. The Judge was competent, and no one can say fairly "My birds ought to have won," unless he first sees those with which they competed.

Wry-tailed Game Cock (*Brown Red*).—Do not breed from him if a natural deformity. It is hereditary.

Pigeon not Eating and Injured by a Shot (*H. Prince*).—If there is any life in your bird it would eat hempseed, which would do it good. Most probably, as it cannot eat, not the wing only but the body of the bird was injured, and by this time it is dead. If alive, bathe with warm water first, and after the skin is well healed a very mild solution of iodine would strengthen it.

Bee Management (*T. H. T.*).—"Bee-Keeping for the Many," which may be had by post direct from this office for five stamps. If you erect a shed let it be a lean-to against a wall facing any aspect from south-east to south-west. It should be closed at the ends, but either entirely open in front, or covered only with pheasant wire, with a good-sized semi-circular opening opposite the entrance to each hive, and should be of sufficient width to admit of all operations being conducted at the back. If you mean to go in for mere ordinary bee-keeping, use only the common cottage hive; if for the depriving system, adopt flat-topped straw hives and supers, such as the "economic hive" which will be described next week, or Payne's improved cottage hive; if for scientific and experimental bee-keeping, you had better go at once to the Woodbury frame-hive.

Death of a Queen (*A Novice*).—The loss of a queen at this season is an irretrievable misfortune. The remaining bees should be at once expelled by driving, and united to the nearest stock, whilst the contents of the hive may either be appropriated by the bee-keeper, or the whole carefully put by intact in a safe place to be again tenanted by a swarm in due season.

Transferring Bees (*G. Cummings*).—No attempt at transferring bees should be made until the hive becomes well populated—say towards the end of April, or during the month of May, according to circumstances, and then the combs should be transferred as well as the bees, or an enormous destruction of brood will be the consequence. It would be useless for any but a very advanced bee-master to attempt the transfer into a bar-hive, but with the aid of frames the task is far less difficult, and the mode of accomplishing it has been more than once fully described in these columns—as for example, in our number for July 22nd, 1869. If, however, you are not able to refer to back numbers, and are desirous of attempting the operation, you can write again, and if desired we shall be happy to repeat the necessary instructions.

METEOROLOGICAL OBSERVATIONS,

REMARKS.

8th.—Dull and damp early, fine evening.

9th.—Very fine day, clear starlight evening.

10th.—Barometer falling rapidly (about 0.07 per hour), a wild, wet morning, barometer lowest at 1 P.M. (29.265 inches), being more than three-quarters of an inch lower than at 9 P.M., on the 9th. Afternoon fine with rapidly rising barometer, and a northerly gale in the evening.

11th.—Very cold day, the shade temperature not rising to freezing point.

12th.—Milder, damp, dull day.

13th.—Fine, bright day, sun quite warm at times, black-bulb thermometer reached 86.2. Fog in evening.

14th.—Bright, mild, genial day, hazy in evening.—G. J. Symons.

COVENT GARDEN MARKET.—February 15.

Very little variation has taken place, the open weather having afforded us a better supply. Our quotations remain much the same. Good dessert Pears are in somewhat better request, also good forced vegetables. Large quantities of ordinary Apples are in the market, and it is difficult to effect sales of them. Large arrivals of Potatoes are again to hand, and only very choice parcels obtain last week's rates.

From observations taken near London during forty-three years, the average day temperature of the week is 47 7°, and its night temperature 32.9°. The greatest heat was 62°, on the 25th, 1868; and the lowest cold 18°, on the 24th, 1860. The greatest fall of rain was 0.92 inch.

THE CAMELLIA, AND ITS CULTURE—No. 1.

[A portion of the following paper was read at the Royal Horticultural Society's Meeting on the 15th inst.]

GIVE a dog an ill name, and hang him," is a proverb that is pretty generally known and understood in every phase of English life. Now I have to deal to-day, so to speak, with a dog that has unfortunately, and, in my judgment, undeservedly acquired an ill name, and one object I have in view in taking up his case is to endeavour to set him right with the public.

Those of us who have any knowledge of dog-nature must be aware that if we keep a dog unduly shut up, or feed him on unsuitable or insufficient diet, unless he be of a very accommodating disposition, he will most likely manifest some signs of uneasiness or displeasure. Now, animal nature and plant nature are much alike in this respect. In dealing with the one as with the other, diet and treatment are everything, and pet plants, like pet animals, are sometimes neglected, sometimes ill-nurtured by improper food, and sometimes fed or worried out of health.

To drop metaphor, the Camellia japonica is a native of China and Japan, and was introduced to this country by Lord Petre about 1739. It was named in honour of George Joseph Camellus, a Moravian Jesuit. Mr. Fortune, who has travelled both in China and Japan, has obligingly given me the following account of the plant or tree in its native countries.

"I have met with the Camellia japonica growing as a wild plant over a large tract of country in the central and southern provinces of China, but its principal habitat lies between the 20th and 30th degrees of north latitude.

"The early spring in the district alluded to is generally remarkably fine, and rather dry. From April to June the weather breaks, and becomes moist and showery. In the end of June and throughout July heavy rains and frequent thunderstorms prevail. In August, September, and October the weather is usually dry and fine. The south-west monsoon, which prevails during the summer months, now changes to north-east, and the weather becomes variable during the latter part of the autumn and winter. Those who know how to cultivate the Camellia in Europe will see at once how well such a climate is suited to its constitution. It has in its native home a winter cold enough and dry enough to check vegetation, and to secure a period of rest; an early and fine spring, during which time the flowers bud forth into bloom, a moist atmosphere in the growing season, and a dry and warm summer and autumn to ripen the young shoots.

"I generally found the Camellia growing in woods where it was partially shaded from the sun by other trees, and in these situations it often attained a height of from 30 to 40 feet. The wild plants have usually single or only semi-double flowers. The foliage of these trees is exceedingly handsome—a dark glossy green. The double-flowered kinds, which have been from time to time imported to Europe, are garden varieties, and are only met with in a cultivated state.

"There are several species of Camellia found in China, but with one exception—namely, C. reticulata, none are so handsome as C. japonica and its varieties, and of these we in Europe have a more extensive and finer assortment than the Chinese have themselves.

"In Japan the Camellia is also found in a wild state. I met with it frequently in shady woods like those in which I had seen it in China. In Japan Camellia Sasanqua is used for ornamental hedges round the gardens near Yeddo, the capital of the country. In November these hedges are very beautiful when the white and rose-coloured varieties of the species are in full bloom."

The Camellias originally introduced by Lord Petre in 1739 were killed by being kept in a hothouse—this was keeping the dog unduly shut up—and some years must have elapsed before the plant was re-introduced, for it is not found in the seventh edition of Miller's "Gardener's Dictionary," published in 1759. Abercrombie, however, includes it in his list of hothouse plants given in the "Garden Vade-Mecum," published in 1789. Several beautiful varieties were introduced from China towards the close of the last and at the beginning of the present century, among them the Double White, the Double Striped, Lady Hume's Blush, Fimbriata, and Imbricata: reticulata, Cup of Beauty, and Princess Frederick William were of later introduction. Others have been raised by English, continental, and American horticulturists. The nurseries of Messrs. Chandler, of Vauxhall, and Messrs. Loddiges, of Hackney (both now abolished), produced early in this century many beautiful new varieties, and the late Mr. Press, of Hornsey, and Mr. Fielder, of Enfield, added to the store.

Mr. Chandler tells me that about the year 1819, a season very favourable for seeding, he saved about half a peck of seeds from the variety known as Warratah, the flowers of which had been fertilised with the pollen of the Double Striped and other esteemed sorts. The seeds were sown as soon as ripe, and vegetated in a few weeks, producing several hundred plants. When two years old, and from 6 to 9 inches high, these seedlings were inarched on the Single Red, and in two or three years they flowered. From this crop were raised Chandlerii, Eximia, Elegans, Florida, Aitonii, Rosa-sinensis, Corallina, Althæflora, Woodsii, Insignis, Concinna, and others.

Mr. Press appears to have been most successful with the Anemone-flowered varieties—that is, those kinds which have a cluster of small petals in the centre, and a row of large petals at the base of the flower. Of these Eclipse, Picturata, and Candidissima may be given as examples. Mr. Fielder's seedlings are more of the florists' type, resembling the old Double White in shape. Two of his seedlings, Jubilee and Rubescens, raised some twenty-five years ago, still rank among the best. Miniata, Lowii, and Alexina were also raised by him. Mr. Fielder tells me that Miniata was raised from Sasanqua and Lepida, and that he still considers Lepida, an old semi-double red kind, with large, smooth, thick petals, one of the best to raise seedlings from

He further says that he has tried numerous experiments with the view of raising seedlings from reticulata and Donckelaeri, but has never succeeded in doing so.

Although other English and Scotch gardeners have been successful in introducing here and there a good variety, the number of English-raised sorts has not recently been great. Judging by the names of the novelties which are now reaching us, we may, I think, reasonably assume that Italy is doing the best work in this field at the present time.

In 1826 Chandler and Buckingham, of Vauxhall, published "Camellia Britannica," a quarto volume with eight plates, and in 1831 appeared "Illustrations and Descriptions of the Camelliæ," by Chandler and Booth, in which some of the finest varieties then known were figured and described. Shortly afterwards was published a work on the same subject by the Messrs. Baumann, of Bolwyller, and more recently a beautiful work by Mr. Ambroise Verschaffelt, of Ghent, appeared, the latter containing innumerable and beautifully executed plates.

The Camellia is by nature a first-class town plant. Some few years ago it was an object of special culture both at Loddiges', at Hackney, and Chandler's, at Vauxhall. It was a great treat to lovers of flowers to visit either of these establishments during the season of flowering. I have seen both collections when at their best. Chandler's young plants always appeared to me the most comely, but Loddiges' large plants were gorgeous beyond description. They were planted out in a house some 30 or 40 feet high, and many of them were pressing against the glass at the top of the house. As you walked beneath and gazed upon the broad, dark green massive leaves, plentifully sprinkled with various coloured flowers, blackbirds, thrushes, and smaller birds fluttered incessantly among the branches, where, with a keen sense to comfort, they had built their nests in this splendid grove of flowering trees. But all this, alas! has passed away, and I know of nothing now in existence that can in any way compare with it. We must turn our eyes in another direction—to the improvement and multiplication of varieties, if we would set up a claim to progress in this branch of horticulture. Some of those old varieties are, doubtless, surpassed by the recent introductions, if we judge them by the symmetry of the individual flowers, and where there were hundreds of Camellias in those days there are thousands now. With this brief historical sketch I shall proceed to the more practical part of my subject.

Everybody acknowledges the Camellia japonica, or Japan Rose, to be a beautiful plant, but many consider it a difficult one to grow and preserve in good condition. This impression derives support from the fact that we often meet with plants which are misshapen and have a meagre appearance, the flower buds sometimes dropping off prematurely. If, however, the plants and varieties be properly chosen, this need not be, except by default of the cultivator. The Camellia may be grown and kept in condition with as little trouble as the commonest of our hardy plants. True, it requires special treatment, and I shall proceed to lay before you the results of my experience in cultivation under the following heads:—

1. Of Soils.
2. Of Climate.
3. Of Propagation.
4. Of General Culture.

And 1st, of *Soils*. Camellias will grow very well in either peat or loam, but it should not be poor peat or loam—the dog will not thrive on insufficient diet. Chandlers grew their plants in two parts loam and one part peat. Loddiges grew them in peat alone, in loam alone, and in a mixture of both.

I have found Camellias grow more luxuriantly in loam than in peat, but they flower more freely in a mixture of both. Some people are accustomed to speak of loam and peat as if these words possessed a precise and definite signification, whereas, according to my experience, they possess a very vague and indefinite one. There is rich peat and hungry peat, sandy peat and fibrous peat, and, *horribile dictu!* sour peat, which is usually gathered in low wet places, and which every good gardener will studiously avoid. Loams vary in a similar manner. The physical or mechanical properties of the soil are of scarcely less importance here than its chemical properties. We want a soil that is open and porous, which it will certainly be if sand and fibre abound in it.

The soil I prefer for the Camellia is composed of three parts sandy loam, and one part fibrous peat and leaf mould in equal quantities. If sandy loam is not readily obtainable, light loam may be used, with the addition of drift sand. To this add a few small lumps of charcoal and a few pieces of crushed bones. Manure, however, I prefer giving principally in a liquid state during the season of flowering and growth only. These different materials should be broken up and mixed together some months before they are required for use, and be turned over occasionally that the component parts may become thoroughly incorporated, and every part be subjected to the mellowing influences of sun and air.

2ndly, of *Climate*. We have seen that the plants first introduced were killed by being kept in a hothouse; it is, therefore, amusing to find old Abercrombie including the Camellia among hothouse plants fifty years later. The fact is, the plant is nearly hardy in the climate of Britain, and the less fire heat employed, except during the growing season, the better. In the flowering season the flowers do not expand kindly, and often fall speedily if placed in heat. In Devonshire, in many sheltered parts of the country, and even in the neighbourhood of London, where the soil is tolerably dry, the Camellia has been planted out both in the open ground and against walls, where it has resisted the frost of several successive winters. It must be told, however, that some varieties are hardier in our climate than others. One of the most skilful of American horticulturists has assured me that some kinds which usually have a delicate and meagre appearance here are exceedingly healthful and vigorous in the climate of New York. We cannot count upon the Camellia as a *flowering* shrub, only as an *evergreen* shrub, out of doors in this country, because the flowers produced under out-of-door culture expand in spring, when they are often quickly spoiled by the variable weather. In order to rejoice in all its beauties we must then use glass structures. In winter and spring it will suffer nothing, when under glass, from 10° or 15° of frost. Both Chandler's and Loddiges' collections were frequently frozen, but never hurt.

When the flowering is over, and the new growth commences, say in March, a warmer climate than we usually experience out of doors is desirable. A temperature of 60° to 70° by day and 50° by night should be maintained throughout the growing season, which we will assume to be March, April, and May. The hygrometric state of the air is not less important than its temperature at this season. Mr. Chandler attributes the dropping of the buds to dryness of atmosphere and too much fire heat. What gardeners call a moist air should be secured by syringing the plants once or twice daily, copiously or lightly, during the season of growth, according to the amount of sunshine experienced. Soot water may be used with advantage in syringing. A close dank atmosphere must be avoided by the admission of more or less air from without, as the state of the weather may permit. By the use of heat and moisture at this season we seek to realise and combine a vigorous growth with a full crop of flowers.

The health of the Camellia is much influenced by sunshine and shade. The plant loves the shade. Some of the most remarkable specimens for foliage I ever met with were planted by myself against a west wall out of doors in my own neighbourhood, many years ago, in a spot where the sun scarcely ever reached them. Shade is necessary during the season of growth, for without it few or many of the leaves, according to the style of the house or the quality of the glass, will become burnt or blistered. The flowers should also be shaded when in bloom. When growth ceases, and the young shoots become partly hardened and the next year's bloom is set, the best climate is that out of doors. Remove the plants from the house, say in June, to a north border where they get the morning sun only, leaving them there till the middle of September, when they should be carried back to the house before the soil becomes saturated with the autumnal rains. These latter remarks, of course, apply only to plants in pots. But where the plants are in the ground under glass, nearly the same effects of climate may be secured by shading and giving air. In a few words, I repeat the climate of England is very near to the best that the Camellia can have. The plant should be treated as a hardy evergreen with two slight exceptions—we should hold in our hands, by means of glass structures, the power of moderating a severe winter should it occur, and the power of giving a slightly higher temperature than that of our climate during the growing season in spring.

I have often been asked, "How is it that Camellias received from abroad, so vigorous and healthful in appearance when they arrive, almost invariably deteriorate in this country?" Some attribute it to climate, others to soil. In my judgment it is due to the forcing system they have previously been subjected to. These plants are grown far too long a period in a hot, moist, shady climate, with the view of obtaining the largest possible plants in the shortest possible time. The hue which captivates is not that of health, but a hectic glow; the plants

are really unsound, and it is no easy matter to restore them to a sound state.

3rdly, of *Propagating*. The Camellia is propagated by cuttings, by grafting, by budding, and by inarching. Propagation by cuttings is principally applied to the species (the Single Red), on which the choicer varieties are grafted, budded, or inarched. Many of the double kinds root and grow well enough from cuttings, and are grown largely in this manner in America; but in this country they appear to grow faster and thrive better generally when grafted on the species. The young shoots of the species, when not over-ripe, say in August, are cut into pieces about 2 inches long, and placed in pots of sand, and set in a close house or frame under glass, where a gentle ground heat is maintained until they are rooted in the April following. They may then be placed each in a separate pot and kept in the same house or frame until they become established in the pots (September), when they may be removed to pass the winter in a cold pit. If heat be given during the growing season of the second spring, these young plants, or stocks, as they are technically called, will be ready for grafting in the following autumn or spring.

Grafting is the method usually applied for increasing the finer kinds of Camellias. In autumn or spring pieces about 1½ inch long, with two leaves on each, may be cut off the plant which it is the intention to reproduce; the lower end of these pieces should be pared flat on one side, and the stems of the stocks being pared in a similar manner, the two flat sides are then brought in contact and bound together with cotton or bast. The plants thus grafted should be kept in a close pit or house for a few weeks, after which period they may be gradually inured to the open air. In spring the dormant buds of the scion or stranger plant may be allowed or encouraged to vegetate, but those of the stock should be kept in check. When the adhesion is solidified the ligature may be withdrawn, the portion of the stock that has been left till then may be cut away, and the stock, or species, is to all intents converted into the variety we have laboured to reproduce. The cultivation of these young plants is henceforth the same as that of older plants.

Propagation by budding may be followed successfully, but as I do not consider that mode so eligible as grafting for the Camellia, I need not occupy your time by entering upon it.

Propagation by inarching was much resorted to in the olden times, and is a sure plan, and a capital one too, if a few large plants instead of a greater number of small ones are sought for. A good-sized branch of any favourite variety may be united to the stem of any less-valuable kind in the same manner as in grafting, except that in inarching the branch is not wholly detached until the union is perfected. The two plants are set side by side, a branch of the one is pared, laid, and bound on a pared branch of the other, and when the union is complete (in a few months), the two are separated, and the inarched plant is treated subsequently as if it had been grafted.

Propagation by seed is principally used to obtain new varieties. Stocks for grafting on are also raised in this manner, but I prefer those raised from cuttings of the species which is of a known hardy constitution, whereas seedlings are apt to vary much in that respect. The seed should be sown as soon as ripe, for if stowed away and allowed to dry the shell or exterior coating becomes so hard that the process of germination is retarded, and the chance of a crop lessened. Sow in pans in peat or light sandy loam, covering with the same soil to the depth of 1½ inch, where there is artificial ground heat. Keep the soil regularly moist. When the germ pushes through the soil, constant shade is indispensable. The seed is often long in vegetating—it has been known to lie dormant for two years—and the seedlings will not usually bloom until four or five years old. I can see no reason why Camellias should not be raised from seed as extensively in England as elsewhere; it is merely a question of cost, and there is certainly no finer field open to the experimentalist. — William Paul, *Paul's Nurseries, Waltham Cross.*

SUBSTITUTES FOR USUAL VEGETABLES.

Mr. Adderley asks (page 66) for information respecting the best substitutes for Greens, &c., killed by the late severe winter.

Parsnip tops I have found very useful when I have been short of Greens. Although they have rather a peculiar flavour, they are not to be despised; the crowns cut off the Parsnip will freely take root, and produce a good crop if planted firmly. Common Turnips and Swedes, if planted on a little bottom heat, would produce a few good dishes in a very short time. Turnips sown now on a warm border would be found very useful, as they almost always begin to run to seed, instead of making bulbs, if sown early. Salsafy and Scorzonera tops make good substitutes for Spinach, and may be blanched like Sea-kale if preferred. Celery makes a very useful dish if boiled and served up like Sea-kale, although we do not often see it used in that way. Early long Radishes will be found very acceptable if boiled and served the same as Asparagus; and if Cucumbers be cooked like Vegetable Marrows it will hardly be possible to detect the difference in their taste.—Lancashire Subscriber.

THE DOYENNÉ D'ALENÇON, alias DOYENNÉ D'HIVER NOUVEAU.

Your correspondent, "B.," has done good service by bringing this old but rather neglected Pear into notice. I received it under the latter name about the year 1840; I find it in my catalogue for 1843 under that name. It was, after a few years, on its origin being known, changed to Doyenné d'Alençon, it being a seedling found in the environs of Alençon. I remember having an argument with the late Mr. Thompson, of Chiswick, he thinking it to be identical with our Easter Beurré—Doyenné d'Hiver. I think he had received the latter sort under the name of Doyenné d'Alençon. I soon convinced him of his error by sending him some leaves. These are most unlike the Easter Beurré, as they are glaucous and downy. The climate and soil of Frogmore—an English paradise of fruits—must suit it well if it bears freely as a standard on the Pear stock. Here it succeeds on the Quince, and its fruit having a family resemblance to the Easter Beurré, is often good till May; in some seasons it fails to ripen, like other very late Pears. It requires, as I have always said, a warm climate. It has been distributed from here to a considerable extent for many years past.

There are two valuable late Pears allied to the Doyenné race, and likely to be hardy and valuable—viz., Duchesse de Bordeaux, *alias* Beurré Perrault, and Marie Benoist. These two kinds ripen in February and March, they are quite hardy, and likely to prove valuable. The finest and hardiest of our late Pears is Bergamotte Esperen. I have eaten one to-day of rather a large size, as it was as large as a Brown Beurré—its flavour and texture as nearly as possible perfection. This sort but seldom fails to ripen well here from pyramids on the Quince stock. Louise Bonne de Printemps, a very handsome Pear, seems inclined to ripen, after our last warm summer; and Olivier de Serres, a spring Nelis, ripens well in March and April, and has not yet failed to do so.

I ought not to forget to mention a fine late Pear, Passe Crasanne, a specimen of which I ate this day (February 12th) a few minutes since; its appearance, yellow and red, very handsome; size, medium or large; and its flesh quite melting, quite juicy, and quite rich, with its after peculiar and grateful aroma. Only one fruit out the locker was ripe and ready. This is a Pear raised at Rouen several years ago. It does well on the Quince, and forms a close pyramid, under which form it has been grown here for a few years. A seedling from it, Prince Napoleon, they say is even better than Passe Crasanne. We shall, I hope, see it this season. I believe it to be good, because the raiser is an honest Norman.—Thos. Rivers.

VARIEGATED PLANTAGO LANCEOLATA.

Plantago lanceolata bids fair to rival, if not to surpass, in beauty the smaller varieties of Funkias, being in its best condition in the spring—an advantage the Funkias do not possess; but it is not of much value during the summer months, owing to the plants during hot weather losing their variegation, which they again regain on the approach of winter.

The variegation mostly consists of broad marginal bands—white, cream-coloured, or yellow, and sometimes there is a central variegation. These forms can seldom be produced from seeds, and the plants must be multiplied by division of the crown, or by cuttings with a small portion of the root stem attached, placed in spring in a slight bottom heat. They quickly make good plants, and may then be planed out. Their low growth and rosette-like appearance render them very attractive.

There are also several varieties of Plantago lanceolata with yellow and yellowish green variegation. These may be pro-

duced from seeds, but are not so attractive as the margined varieties.

I have also had some nice variegated varieties of Plantago major and Coronopus, but find them difficult to increase. However, I can see sufficient indications of different forms of variegation in the Plantago family to warrant my predicting they will find a place in the select herbaceous border, and become welcome additions to the best collections of hardy variegated plants.—W. E., *Gardener, Cromwell House.*

THE EFFECT OF GAS LIGHT ON PLANTS.

If there is any branch of gardening for which I have a special liking, it is that of growing plants for house decoration; and if there is any part of my duty which I sometimes feel reluctant to perform, it is after growing my plants to have to subject them to the destructive influences of gas. This, perhaps, is only a natural feeling, and it is surprising how easily and almost imperceptibly such a feeling wears off when a person considers that it is just his duty to do that which is required of him, and if employers are satisfied, why gardeners should be so likewise. But it has occurred to me that as many, if not most, of the private residences of the wealthy, both in town and country, are now lighted with gas, and plants for house decoration were, I think, never in greater demand than at present, I cannot do better than devote a short paper to the subject. Though my experience is rather limited, yet, as the matter is of great importance to gardeners generally, I hope that others will respond to my invitation and state their experience also, so that gardeners and purchasers may know better what plants to grow or buy for the particular purpose in view.

Although I do not know of any plant that will even live for any length of time, not to say grow, in an atmosphere strongly impregnated with gas, yet a great variety of plants will withstand gas for a surprising length of time, though not without injury; while there are many that are injured beyond recovery in less than one night or day. The flowers of plants are generally the first to suffer; the thick petals of the Orange flower and Camellia, and the more delicate petals of the Persian Lilac, Begonia, Pelargonium, Myrtle, Daphne, Rose, Deutzia, Fuchsia, Datura, Salvia, Acacia, Tulip, and Crocus, fall as suddenly as if by magic, and with less than two hours' exposure to gas light; while the flowers of the Hyacinth, Cineraria, Spiræa, Primula, Gesnera, Epacris, Heath, and Poinsettia will bear up for a considerable time, the last-named especially; its showy bracts shrivel up, but do not drop. Of the foliage of the above-named plants, that of the Poinsettia, Orange, Rose, Lilac, and Cineraria are the first to show signs of distress, while the leaves of the others will mostly turn yellow or become sickly-looking before dropping off. Next come plants with ornamental foliage. Of these, the leaves of large-leaved Solanums, Colenses, Acacias, Farfugiums, and Wigandias suddenly curl up, and as quickly fall to the ground; and those that stand the longest without showing distress are Richardia, Ficus elastica, the strong-growing Caladiums, such as pictum, esculentum, and atropurpureum; Maranta zebrina and Porteana, Gesneras, Crotons, and Ferns. Isolepis gracilis must also be included. I observe that fine-foliaged plants are more ornamental by gas light than flowering plants, excepting, perhaps, the gaudy floral bracts of the Poinsettia. This plant is quite an exception; it will enliven the dulness of a bank of evergreens, it bears the heat and gas well, and is a favourite with everybody.

Unless large quantities of plants should be required for special occasions, I presume the most expensive plants in the list I have given would not be used, nor should I advise it, for it is not difficult to compile a list of plants easily grown and comparatively inexpensive, and that will resist the influence of gas tolerably well, so that less loss would be incurred if it should prove fatal to them. These plants consist of greenhouse Ferns, such as different kinds of Adiantum and Pteris, Richardia æthiopica, Primulas, Cinerarias, Lachenalias, Myrtles, Gesneras, Ficus elastica, Isolepis gracilis, Poinsettias, Hyacinths, Epacrises, Heaths, and some hardy evergreen shrubs, such as Thuja aurea, Cupressus torulosa, variegated Box, Euonymus, and the like. These are all dwarf-growing and manageable plants, but, doubtless, many more may be added.

I avoid as much as possible sending in early-forced shrubs and plants, such as Lilacs, Deutzias, and Ghent Azaleas. It often happens that many of the rooms to be decorated are heated to a high temperature, and, being a dry heat, it proves hurtful to such plants as Heaths and Epacrises, which have very fine hair-like roots; the life is dried out of them. A good plan, when it can be adopted, is to tie some damp moss round the pots; it preserves the roots remarkably well.

So far I have only noticed the behaviour of plants in heated and confined rooms, with little or no ventilation, and with the gas jets arranged close above, or may be below, many of the plants. In such positions, with the fumes of gas rising upwards, the plants are at the greatest possible risk of being injured; but whether in large or small rooms, I think the injurious effects of gas upon plants will be found to be small in proportion to the amount of ventilation given, and the facilities afforded for the escape of the impure air before coming in contact with the plants. Of this, however, I am not certain, and I should like to hear from others having more experience than myself, for gas-lighted structures are becoming so common, and the information as to the best plants to put in such places is so very scanty, that I hope to refer to the subject again at some future time when I shall have gleaned more experience. —Thomas Record, *Hatfield.*

HOP CULTIVATION FOR ORNAMENT AND USE.

No. 2.

Propagation and Culture.—Having noticed the soils on which the Hop is often grown, we now come to its propagation and planting, the former being a simple affair, the latter often preceded by some expensive operations on the land. I shall, therefore, commence with planting, and say that when it is determined to make a new plantation it is usual to select one of the best plots of ground the farm possesses, and if it should have already been in tillage (which land, I may remark, is not considered so desirable as that which has been under wood, orchard, or grass), it is ploughed deeply in the ordinary way, and also subsoil-ploughed; or, what is better, and very frequently done, the surface is ploughed in the usual way, and a gang of men—ten, or perhaps a dozen—follow and dig up the bottom of the furrow before the plough returns. By a suitable arrangement of man and horse power this can very well be done without loss of time to either, and is much better than subsoil-ploughing. Trenching is not unfrequently performed, and in the case of woods, coppices, or orchards the removal of the roots generally effects the same purpose as trenching, and Hops like such land better than that which has been long under tillage; the consequence is that in many places coppice wood has entirely disappeared, only steep banks and a few patches being left for shelter or game.

Supposing a plot of ground to be ready for planting, some one well used to marking out the ground is generally employed to set it out, as great exactness is often exercised in doing this. The most common way is to have what is called a "square plant"—that is, the rows are at right angles to each other; some, however, prefer the triangle, or what gardeners would call quincunx order, both often containing about the same number of plants per acre, generally 1210, they being placed 6 feet apart each way in square planting, and something more in the diagonal measurement of the "triangle plant." Some planters give more space, but the majority only as much as stated; and a great portion of the work in the Hop garden being done by the piece, it is customary to regard 1200 plants, or hills as they are termed, an acre. In setting out a new plantation care is taken to have the line as straight as possible. An ordinary garden line with a piece of red worsted stitched into it at every 6 feet is sometimes used, but as the line is apt to stretch in dry weather and contract when wet, some check is used along with it. A chain made on purpose is more accurate. In the setting out, a stick is pushed in where the plant is to be, and the planting is done all together; I will, therefore, take the preparation of the plants next.

Although the Hop produces seed in as great abundance as most plants, it is never propagated in that way, except for experiment, the seedlings differing so widely from the parents, and a considerable portion of them being very often what are called male Hops—*i.e.*, not possessing the bitter quality which gives value to the Hop. It is, however, a disputed point amongst botanists of the Linnean school whether the plant belongs to the twenty-second or twenty-third class of that system, as the same plants which produce male Hops one year may produce a few female ones the next, and *vice versâ*; accordingly the great body of growers carefully eradicate all male plants as they appear. Others again affirm that a few male plants in a plantation are an advantage rather than otherwise, and plant

one to a hundred or thereabouts, insisting that the ninety-nine bearing plants with the aid of the one male plant produce more than a hundred all of a kind. Whether it be so or not, it is certain that the presence of the male plant is not necessary to insure good seed, as that is produced whether it be near or not. But as plants for general use are not obtained from seed it is needless saying more on this head, I will therefore at once pass to the mode in which Hops are generally propagated, which is simple enough.

The Hop being an herbaceous perennial its stems die down to the ground every winter, but as the gathering of the crop renders it necessary to cut the bine in the centre long before the sap has ceased to rise in the stem, much injury is unavoidably done to the plant, but to render this as small as possible the bines or stems are cut as high as they conveniently can be consistently with their standing upright without support, for the poles to which they cling are removed at this time, and to cut the bine at a greater height than 2 feet from the ground would cause the tops to bend over, hang down, and bleed. The bleeding is said to weaken them, and great care is therefore necessary to prevent it. In February or early in March what is called the dressing has to be attended to, the whole of the ground having been previously dug, and the necessary dung, &c., added at the same time. The dressing here alluded to is the winter pruning, which is accomplished by scratching away the earth from the crown of the plant with a short-handled tool made for the purpose, and the shoots which have been standing all the winter are cut off close to their junction with the crown of the plant. As they are often buried in a slanting position in the ground, there will be 6 inches or more that has been in the soil, and this part is frequently swelled to the thickness of a broom-handle, with some roots emitted, as well as embryo shoots. These cuttings, called sets, make the plants used for future plantations, and they may either be planted in their places at once, or, as more commonly practised, bedded-out one year in a nursery ground, whence they are transplanted to the ground allotted for them. Two or three are planted on a hill, unless plants are very scarce, when only one is used, as is the case with a new or scarce variety. The growth of the bedded sets being, of course, better that that of the mere cut ones, larger poles are required, a single pole of 6 or 7 feet high being sufficient for sets not previously prepared, while the latter require more than one year's growth ere they are treated to what is called a full pole.

Poling.—After the old Hop ground has been dressed or cut, and when the young growth is a few inches high, it is time to put in the poles; in fact, this might be done earlier, only the shorter time poles are in the ground the better, to prevent their decay. Poling is often performed in April, and as Hop poles form a very important feature, as well as a very heavy item in the expenditure, I may state that for the taller kinds of Hops it is a common practice to put alternately two and three poles to each hill, or about 3000 poles to the acre of 1200 hills. In placing the poles, their sharpened ends are struck into the ground with a smart jerk, a hole having previously been made by an iron implement called a Hop-pitcher. The bottoms of the holes are about 16 inches apart, but the tops are somewhat more, care being taken at the same time to keep them as straight as possible in the direction called the main line; but whatever care be taken, it must be admitted that a piece of ground covered with naked poles has not by any means a picturesque appearance.

Trimming and Tying.—We now come to the management of the growing plant, the first operation after the poles are put in being tying the young shoots to the pole to start them. This is invariably done by women, who, by practice, become very expert at it. The young shoots, growing rapidly, must not be allowed to become too long ere they are tied to the pole, otherwise they get entangled with each other in a way difficult to remedy; at the same time they must be long enough to reach to the pole, or nothing can be done with them. Some growers like the most robust shoots tied in, but the majority reject them, and prefer the middle-sized, short-jointed, rather wiry shoots as being the best. All agree that about three shoots are plenty for a pole, and sometimes only two are preferred. The shoots are tied to the bottom of the pole by a sort of sliding tie, which gives way when the bine increases in size, and they quickly take to the pole, but they have to be looked over again in about a week, and if not climbing up properly another tie has to be given. They are then often about a yard high, and at this time, or when they may be somewhat higher, all the surplus shoots are pulled off the crown of the plant, and two or three spadefuls of earth are put upon it. After this it is seldom any more shoots appear there during the season, the whole energies of the plant being directed to the growth of the bine running up the poles, which it does in the spiral direction common to all climbers, excepting the Kidney Bean, which twines the reverse way. The growth of the Hop, when the plant is 6 or 8 feet high, is often very rapid if the weather is fine at the end of May, when the growth frequently exceeds 6 inches in twenty-four hours, mild moist days and warm nights being the times when this plant is supposed to make most progress, which, however, is often arrested by enemies difficult to deal with, and sometimes the weather is not propitious. At this time the cares and anxieties of the Hop-grower begin, and they do not cease until the crop is gathered, and I may say sold and paid for, as few plants are so liable to mishaps as the Hop. The means taken to combat its insect enemies being such as a gardener may study with advantage and take hints from, I will make no apology for entering at length into this department, being convinced that the bulk of the gardening community have a very imperfect knowledge of what the Hop-grower is doing in this direction.—John Robson.

CALCEOLARIA FAILURES.

I have found, in almost every instance, the cause of Calceolarias failing, of which Mr. Robson complains, is their being planted in poor, sandy soil, incapable of retaining moisture for any length of time; consequently at the first period of dry weather the roots are burnt, as will be found upon taking up the plants and examining them.

In taking cuttings in September I always give the preference to short stocky shoots cut off with the heel. I insert them in large 60-pots, six in a pot, using equal parts of leaf mould, drift sand, and chopped moss, with plenty of drainage. I then place the pots upon coal ashes in a cold frame, which I always set facing the west. I plunge the pots in water before putting them in the frame, and but little water is needed till the cuttings are rooted. After they have struck admit air by raising a little the bottom and top of the light. I never take off the lights entirely till the beginning of March, for I consider it gives the plants a check, which I always avoid if possible.

At the beginning of February I pinch out the top, and at the end of the month I plant out in a frame on a warm border, placing the plants 4 inches apart every way, having previously prepared the ground in the following manner:—I take out 3 inches of soil, then fill in with 3 inches of rotten dung beaten firm, and cover the dung with sufficient soil, consisting of leaf mould, turfy loam, and drift sand in equal parts. After planting, keep the plants close till they are again established, then give them as much air as possible, taking off the lights entirely as the season advances.

In taking up the plants, cut round them with the trowel, and lift them with the ball entire. In planting out, choose a mild day early in April, having previously exposed the plants night and day for at least one week.

In preparing the beds I take out the soil to the depth of at least 1 foot, and fill in with 6 inches of good rotten dung pressed firm, and 4 inches of rough turfy loam, such as we use for Cucumbers, keeping the beds at least 2 inches below the walk or lawn. If the beds are to be occupied with other things, remove 1 foot of the old soil and fill in with good turfy loam, which agrees with all bedding plants, with the exception of Coleuses, which need an addition of sand. The most important point of all is to give water before they become too dry; when once they flag no amount of care will bring them round. I use manure water, tolerably strong, alternately with pure water, watering in the evening during dry weather twice a-week, and giving at least one quart of water to each plant.

I place the frames used in protecting the cuttings in a turf pit, and fill in between with litter. This, with a few mats thrown over during severe weather, will keep all safe.—W. Clark, *Cheshunt, Herts.*

AMERICAN POTATOES.

In answer to Mr. Rivers's observations on the American Early Rose Potato, I am very sorry indeed to find that he is so prejudiced against the "Yankees" and their Potatoes. I wrote to your Journal a short time since, mentioning the good qualities of, and highly praising the Early Rose for its heavy cropping, good size and appearance, and first-rate cooking pro-

perties, and I still affirm, having thoroughly proved it, that it is one of the best Potatoes in cultivation.

I am afraid Mr. Rivers puts too much confidence in his cook, for he says, "they were found to be harsh and dry, with a hard centre." This proves to me that they were improperly cooked. I should advise Mr. Rivers, before pronouncing such a strong condemnation upon them, to cook them himself, and if one way fails, to try another—not that this Potato requires any different method of cooking from any other. I do not wish Mr. Rivers to become a cook; but where the character of such a noble variety is at stake, and when amateurs and others might be misled, and be prevented from knowing the true character of this excellent Potato (for the pen of Mr. Rivers is greatly depended on by this class), it would be more satisfactory if he tried them himself. This is not the first, second, or third time I have known Potatoes condemned through bad cooking, and I fancy myself to be an adept in cooking Potatoes, for I have several times turned them out fit for anyone's table when good and professional cooks have cast them aside as a bad sort.—J. C. Lewis, *Sudbury, Derby.*

HOW AN AMATEUR GROWS GRAPES SUCCESSFULLY.

Having satisfied myself that it is a very easy and pleasant occupation to successfully grow Grapes under glass with scarcely any artificial heat, and at a very moderate cost, without neglecting my usual daily employment (being absent from home ten hours per day), I feel desirous of stating what I have done during the last three years.

My residence is about a mile from one of the central towns, and it being a detached cottage facing the west, I was recommended to build a lean-to glass house on the south side as a vinery and general greenhouse. A builder, who knew his business, contracted for £30 to erect one the full length of my dwelling, 30 feet long, 9 wide, 8 high in front, and 13 at back, with a door leading directly into my dining-room and one into the garden. I then put a double row of 3-inch piping for hot water, about 90 feet in all, along the front and both ends, partly below the floor for the convenience of the door, the remainder about 6 inches above the floor, and covered with latticework; on the outside, at one end, I had a pit dug 5 feet deep and 3 wide to hold a small copper boiler for heating the water by gas. This apparatus complete, including piping and fixing, cost £15, and it answers admirably.

Being quite ignorant of Vine culture I wrote to your office for the "Vine Manual," which I read carefully, and, in addition, asked the advice of an old gardener, who recommended me to make an outside border, 3 feet wide and 2½ deep, along the front and ends of my new house. This border was composed of two kinds of turf, quite fresh, from heavy and light soil, cut up into pieces from 3 to 6 inches square—three barrowloads; of light loam two barrowloads, and about one barrow filled with lime rubbish, oyster shells, small bones, and horse manure. Being a light porous subsoil, no drainage was required. The border was elevated 6 inches above the surrounding ground, gradually sloping from the house, and finished in February, 1868, the materials being mixed together before they were put into the hole.

In about six weeks, having given the border time to settle, I sent the gardener to a Vine-grower for some year-old plants; he bought two Black Hamburghs, two Alicantes, and one Old White Tokay for, I think, 30*s*. They were set in April, 1868, not more than 1 inch deep, and the canes brought into the house through holes in the wall a little below the level of the border. Over the roots of each was put half a barrowful of light, fresh stable manure, to produce warmth and to encourage growth. The Vines soon began to grow, and were allowed for the first year to run over the house without any pruning, and only one bunch of Grapes was left to each. They were cut down in January, 1869, leaving two or three good canes to each; next season they were permitted to grow freely with very little pruning, and to bear five bunches of fruit each. 1870 brought me good, strong, healthy Vines, with from forty to fifty bunches of Grapes upon each. I allowed one hundred and fifty to ripen, and began to cut the fruit early in October, and continued cutting till January 15th, when I had 30 lbs. of good, sound Grapes, having had nearly 130 lbs. of fresh ripe fruit during the season—four months; some of them are not eaten yet, February 10th.

The cost in labour has not been 20*s*. since they were first planted. I only employ a man to cut the Vines down in January, and to paint them over with a mixture of soft soap and sulphur. I let the canes lie down until they have started in spring, then tie them up to the wire fixed crossways in the rafters, and continue this about once a-fortnight during the season.

The most troublesome job was thinning the fruit. I cut away several pounds' weight of Grapes, and yet I am told I should have had much finer fruit had I thinned them more. All branches bearing fruit I kept well pruned back to the second joint, excepting the thickest leading canes, which were allowed to make strong new wood for another season.

I find the most particular times are while the Vines are in flower, and in September when the fruit and wood require to be well ripened. The latter period was the only one at which I required to use artificial heat, but it is most important that the wood should be of a nut-brown colour, and thoroughly ripened.

In spring and autumn I have the house shut up early in the afternoon with a little air; in summer the top ventilators remain open day and night. My maxim is, Always give air, much or little, according to season, when the sun shines, and not any artificial heat, excepting on cold days in September, and then give all you can with plenty of air.

Were it not for my general collection of plants I should not require the gas on during more than twenty days in the year; as it is, the number of days on which I use it does not exceed forty in ordinary seasons. My house being well sheltered from the north winds, 5° or 6° of frost are of no consequence, providing it is well shut up. My better half soon learned these few rules of ventilation, and thus our united efforts have been crowned with success.—F. H. W.

ICE ON GLASS ROOFS—GLAZING—HEATING.

We have been struck with the very timely and useful remarks of Mr. Pearson at page 63. The house referred to at page 50 as having a short terminal square of zinc resting on the wood in front, instead of the glass coming down all the way, is the steepest-roofed house we have, the roof coming down to within a foot of the ground, and the front sashes as well as those at the back are moveable. The roof is at an angle of 45°; the steepness, therefore, was all in its favour, yet from the snow melting and sliding down outside, and condensed moisture trickling down inside, there was a few days ago a ridge of ice along the front of the house fully 4 inches deep, resting on the wood of the sash, the zinc, and a little on the glass. We allowed it to thaw before moving it, being afraid to break it off lest we might injure the glass. This house is 50 feet in length, and as yet only one square has been broken by the frost, and that close to the zinc. The squares are rather small—about 8 inches; and as so far confirmatory of Mr. Pearson's remarks, they are cut on the curve instead of the square, and with rather better than one-eighth of an inch of lap. The rounded lap looks the neatest, but we cannot say that in past times we have found it stand frost better than those cut straight across. The statement of Mr. Pearson is therefore all the more important, and we trust that others will note and report their experience on this matter. Then, again, were we putting up new orchard houses we would follow Mr. Pearson in using glass 14, 15, or 16 inches wide instead of 20 inches or wider. Such a size is not only more secure but more easily repaired when there is a breakage. As to weight, most of us would prefer 21-oz. to 15-oz. glass if we could get it. We would have no objection to even a much heavier good glass, believing that it would not only be more secure in general, but act in some degree as a regulator of temperature. There is just one fact that came under our notice that we would like to mention, and we would be glad to know if any reader has met with a corroborative case. A severe summer hailstorm that cracked and broke a good deal of 21-oz. glass, scarcely cracked a square of 16-oz. glass. We expected to see roofs of squares 20 inches wide riddled, and at some risk to face and hands turned out to see the smash which we would be powerless to prevent. It was a pretty sight, nevertheless. The 15-oz. glass yielded and gave to the hailstones, and was uninjured. The heavier glass did not yield, and was cracked and broken. This is the solitary case that we know, in which the thinner lighter glass proved superior to the heavy glass.

Then the testimony of Mr. Pearson is most important as to the bad results of dispensing with laps, and placing the nicely cut squares edge to edge. A great many roofs have been covered in this way, a great number, we believe, on the patented

principle of Mr. Beard. Would some who have tried this plan give us details as to how it passed through the late severe weather? United testimony on this matter would be most valuable, and especially in ornamental houses, as in them the laps often become eyesores.

We trust that even the amateur who purposes putting up a house or two for his pleasure will ponder over what Mr. Pearson says of cheap imperfectly annealed glass. It would be well if there were some simple test beyond appearance for detecting glass not properly made. At present we must depend a great deal on price and the character of the glass merchant. We have known cases in which very bad scored and spotted glass was obtained at the price of good glass. The rage for cheapness, however, is so great that it is no wonder that clever people are frequently taken in, and find that cheapness is just another word for dearness and discomfort. A few years ago a gentleman who was resolved to have a cool house as cheap as possible, showed us a fair specimen of some glass he could have for about 1*d.* per foot. We stated we should be sorry to use it at any price. We grounded our opinion on the colour, the warpings, scratchings, and blotchings. However, like many people who ask advice and have already resolved to have their own way, the glass was purchased, and hardly anything could be kept under it without having the leaves blotched and burned, no matter the amount of air given. This we expected, but we did not expect that as soon as the first frosts of the autumn came the squares would begin to crack and fly in all directions. After the second summer all had to be replaced. How are we to know when the annealing is all right?

As so much has been said on heating of late, we may mention that we went one afternoon to see the new stokehole and boilers placed in a little wood at Luton Park. Two boilers are placed side by side, to be worked singly or unitedly, one being deemed sufficient in ordinary weather to heat the whole establishment, with its many ranges of glass. We have mislaid and forgotten some of the details, but most likely we shall revert to them ere long; meanwhile we may remark, that no better example could be given of the economy of heating large establishments by hot water, as there is only one low chimney instead of many, and this being 60 or more yards from any of the glass, there will be no dirtying of the houses by blacks, &c. The boilers, placed side by side, and working unitedly or separately, secure safety, as it is scarcely likely that both should go wrong at once.

The main flow and return from the boilers go through an arched tunnel, deep enough for a man to pass along, and from these other main flows and returns are taken off as wanted. This conduit or covered passage being shut at each end, the pipes are found to contain a great reservoir of heat; and important, as bearing on some statements lately, the main flow in the conduit does not only rise a little all the way, but the other secondary flows to all the houses also rise from them; and from these, again, the heating pipes of each separate house rise considerably, so that the lowest pipes even for bottom heat are considerably higher than the main flow and return, and still more elevated above the boiler. As respects heating, nothing could answer better. But let those thinking of such a plan bear in mind that here there is no lowering of pipes, all are above the boilers. Lastly, for the present, after trying many boilers and systems, these new boilers at Luton Park are just the old simple saddle-back.—R. F.

AN IVIED WALL.

There is nothing to my mind which gives a greater degree of comfort and snugness, combined with a cheerful home feeling, than *well-kept* Ivy walls. I emphasise well-kept, because their beauty mainly depends upon a little care and attention, and a very little will suffice to keep them in beautiful order.

The Irish Ivy, so called, is best suited for the purpose. It should be planted in good soil and occasionally watered, and if with a little liquid manure it will grow the more rapidly. Care should be taken to cover the whole wall, but the main secret for keeping it in beautiful trim is every year to cut it closely at the beginning of March. It will, of course, remain bare and unsightly for a week or two, but the new leaves soon compensate for the temporary dullness, and give a lovely green surface that will delight and soothe the eye all the summer and winter.

At a late residence a wall 40 or 50 feet long and about 10 feet high ran along the flower garden, and I covered it in this way, adding, at the same time as the Ivy was planted, some of the strongest-growing Bourbon Roses. By adopting the plan above recommended the effect was admirable, and elicited the praises of all who saw it. If a good syringing can be given to the Ivy from a garden engine in the course of the summer, it will add much to the effect.—Hortator.

VERBENA PLANTS SHRIVELLING.

Like "R. F." we lost most of the Verbenas here in the way he describes. I could form no idea of the cause; they were struck in the usual way—that is, about eighteen cuttings were inserted in a 6-inch pot in September, and plunged in bottom heat until well rooted. Then they were gradually hardened off before storing them in their winter quarters, and all seemed to be thriving well until they were attacked just before Christmas with dark brown spots, first at the tips of the shoots. These spots seemed to gradually wither the plants up. I tried flowers of sulphur to no purpose. The disease seemed to me to attack the Verbenas in the same manner as the Potato disease attacks the Potatoes, and for both I have failed to find or hear of a remedy. I may mention that Purple King and Crimson King suffered the most.

I am glad to say I have not seen any signs of the disease this season. The plants received just the same treatment last season as they have this; they occupy the place where the Verbenas have stood for several years. I hope some of your correspondents will be able to find out a remedy in case of future attacks.—S. W. J.

THE RIVERS PORTRAIT.

At a meeting of the trustees of the Lindley Library held on the 15th inst., Dr. Hogg presented, in the name of the subscribers, the portrait of Mr. Thomas Rivers, of Sawbridgeworth, to be held in trust by them as part of the property of the Lindley Library. The portrait, which is a beautiful picture and an admirable likeness of Mr. Rivers, is now suspended on the walls of the large ball, on the right of that of Dr. Lindley. It was painted by Mr. I. T. Peele, of Grafton Street, Fitzroy Square, and bears strong evidence of his high attainments as a portrait artist.

REPORT ON THE STATE OF THE VINES—PRACTICE AND PROPOSED ALTERATIONS.

[The following report from a gardener to his master contains information which may be useful to others who possibly may be in somewhat similar circumstances. Gardeners should keep in mind that a mistake, or an unfortunate termination to a previously unexplained measure, may be to them of serious consequence.]

With the exception of two White Frontignans and one Buckland Sweetwater the Vines are all Black Hamburghs.

The Past.—About fifteen years ago a new border was made, the old Vines being lifted and some young ones put in. The border is of the same length as the houses, 10 feet wide and 3 feet deep, including at the least 6 inches of broken stones and rubble. It cannot be widened. The soil is yellowish loam, not turfy, of medium texture, and mixed with some charcoal. The Vines have not been forced; they have been worked on the spur system and have borne uniform crops of excellent Grapes with but little shanking. The border has had frequent surface-mulchings of fresh soil and some sweet decayed manure. It has been covered with wooden shutters during the winter. I should add that immediately in front of the border runs a gravel walk, and beyond the walk kitchen-garden ground. The roots are not confined to the border by a partition wall of any kind.

The Present, commencing 1869. During this year I observed that the spurs pruned the closest produced Grapes inferior in size of bunch and general finish to those hanging from spurs which had been left longer at the winter pruning. During the summer I noticed the growth was unusually vigorous and rather coarse in wood and foliage. An abundant yet careful amount of air was given, and the houses never entirely closed at night; indeed they were, as they always are, worked at a low temperature. The Vines were allowed to carry as much foliage as possible, carefully preventing overcrowding. The shoots were stopped at two or three leaves beyond the bunch, and from this point the laterals were kept timely and continually pinched. My opinion at the time was, that the excessive growth was attributable to the roots passing under the walk and into the garden. I looked but could find none, still, however, hold

ing to my opinion. At the winter pruning, taking advantage of my above-mentioned observations, I purposely, and I may add fortunately, left several spurs longer than usual, and also in places laid in some young wood. This year's crop has been as good as usual, but the long spurs and the young laid-in wood have produced it. There has, however, been rather more shanking than usual, but still to no serious amount. One thing is clear—had I pruned the Vines on the usual short-spur system the crop, if it had not been a failure, would have been very far below the usual standard. The strongest and most vigorous Vine in the house, and so pruned, produced scarcely any Grapes at all.

Another search for roots in the garden beyond the walk, and I found them in plenty at depths of from 1 to 2 feet. Most of the roots found are healthy and fibrous, some others are not so. I would particularly observe that the garden ground in which the roots are now ramifying is good to the depth of 2 feet, then comes a foot of sour hungry loam resting on a bed of soft buttery-looking white marl. I now look at the Vine border proper, the 10-feet border. At a foot below the surface I begin to find roots, but as destitute of fibre as any other water pipes, for this is what they amount to. The feeders are in the garden over the walk foraging for supplies to send up by these channels to supply the Vines. The Vines now get little or no sustenance from the 10-feet border. A prime cause of the Vine roots leaving the border may reasonably be attributed to three excessively dry summers driving the roots outwards and downwards in search of the required moisture which fell in such diminished quantities from the clouds, always remembering that they were naturally predisposed to ramble in search of fresh food, having during their growth extracted from the narrow border the particular aliment necessary to their sustenance. In the last-mentioned premise, I would incidentally mention, is to be found the reason why young Vines will not grow in old Vine borders. I have as briefly as possible, consistently with clearness, noticed the past and present, and now proceed to

The Future.—To insure good crops of good Grapes in the future, a different system of management must be adopted. As long as the roots were confined in the border and near the surface, the spur system was right. There was something like a balance between root and branch. Now that the roots have taken a wider, almost unlimited range, the reciprocal action of root and branch is destroyed. The canes are 18 feet long. The roots are found 36 feet from the house, and it is quite probable that they extend further than this. The balance lost must be restored, or the Vines one by one will probably follow the example of the one which is the most vigorous, and refuse to bear good fruit. There are two ways of restoring the necessary reciprocal action—one by commencing operations on the roots and branches conjointly; the other by top or branch management alone. The latter plan is the simpler, being the system of letting a Vine have room to extend itself by cutting away the other Vines as it grows, and so letting it occupy several rafters or a whole house. The branches would soon be on an equality with the roots, and I am sanguine good Grapes would be the result. The drawback to this plan is the buttery-looking white marl subsoil, which suggests the question, Would the roots penetrate into it? If so, shanking would inevitably ensue. Whether the roots would enter this uncongenial soil is to me problematical. I think they would not, considering they have the range of 2 feet of good soil above it. I, however, hesitate to recommend it on my sole responsibility on account of the important question it involves. The former plan of root-and-branch action conjointly is to remove the soil from the border, entirely laying bare the fibreless roots, and to make them fibrous by covering them with 5 or 6 inches of proper soil, and this again with heating material of manure and leaves to the depth of 2 feet, or sufficient to give a gentle warmth to the fresh soil above the roots. This warm fresh soil would induce the emission of a network of spongioles from the old roots, essentially of a health-inducing and fruit-producing character. Surface-feeding roots of this nature predispose the top growth to short-jointed fruitful wood, and the spur system of pruning is quite in harmony with the practice. This, with young canes brought up and worked on the spur system, in conjunction with a general system of proper management, never fails to bring good Grapes. I do not say that one covering of heating material would answer the purpose of always keeping the roots near the surface. It might be required in the first instance for two years consecutively, and then, perhaps, every alternate year to keep the Vines in permanent good order. The limited number of Vines, and the demand on them, do not permit of experiments involving the risk of a loss, or partial loss of crop.

The two methods put side by side stand thus—

1st. Letting the roots alone, and working the top on the long-rod or extending system. This I am certain would answer, except on account of the white marl subsoil, and, perhaps, in spite of it.

2nd. Raising the roots by surface heat and working on the short-spur system. This involves more labour and material. It would answer.

Taking everything into account, which is it to be? What say the Editors, or their practical correspondents?—W.

[Many years ago the modes of pruning Vines were prominently referred to, and they have been noticed frequently since. It has been shown that with all the advantages of the short-spur system when the roots were near the surface, long and short rods in succession answered better when, from depth of roots, the wood was apt to be stronger, but pithy and long-jointed. The example you adduce of the vigorous but comparatively barren Vine is a case in point. If the strong wood from that Vine were well ripened we have no doubt it would be very productive the following season; but then we should be doubtful if spurring would answer in the succeeding year if the extra vigour showed the roots were deep and in moist soil. We do not place so much importance on the extension of roots and of branches being reciprocal. We think it very likely that there are more fibres in the original border than supposed, and if not, then the mere length would be of little importance if so much of that length were destitute of feeders. We have no fault to find with the gradually-extending system, so as ultimately to have a few Vines, or only one, in a house; but we have no faith that the mere extension of the stems will alter the character of the Vines, if, as you suspect, the roots, owing to the dry summer, have gone down in search of moisture, as we believe that then, as well as now, the young wood successions would be better than close spurring—that is, supposing you make no other alteration, except merely giving the Vines more headway.

From the examination of the roots in the garden they do not seem to be too deep there; but if allowed to get dry they will go down after moisture into the uncongenial soil, and that will be best prevented by surface-mulching and surface-watering when necessary. You are not likely to have excess of moisture with this marl bottom at 3 feet from the surface, and unless the roots, from want of moisture above, are induced to go into it, we have no doubt you will have good Grapes on the short or long-rod system instead of close spur-pruning. Instead, therefore, of adopting one of the plans you propose as first and second, we should be inclined to adopt both. We would first allow the roots in the garden to remain as they are, and encourage them to keep near the surface by mulching and watering when necessary; and secondly, we would carefully remove the soil on the old border down to, but not so as to hurt, the roots, cover with a few inches of gritty fresh soil, and then add a little loam, with a slight hotbed over it as you propose.]

SEEDLING PINE APPLES.

I BELIEVE there are not many gardeners who have had much experience in raising and cultivating seedling Pine Apples. It is a subject seldom spoken of or commented upon in the horticultural press. It so happens that I have thirty-four distinct varieties of seedlings under my care at the present time. In many instances their characters are very distinct from each other, and easily detected at first sight by cultivators of the Pine Apple. One of them is likely to become the tallest and most robust in cultivation, while at the same time it forms a plant of handsome proportions, its leaves being as straight as an arrow and covered with an unusually dense and light-coloured bloom, the spines being wider apart than in any other variety with which I am acquainted. This plant has been grown under great disadvantages, as I was never able to keep the bed in which it was plunged at a temperature of more than 60°, in consequence of the hot-water pipes settling down late in the autumn, and, owing to circumstances, they could not be raised to the proper level till the following spring. The sucker from which the plant was grown was weak, having been taken from a sickly plant which had to be stripped of every leaf, and scrubbed and otherwise cleansed to get rid of scale. The small sucker made its appearance from this roughly-handled

stool late in the autumn of 1868; and on the 2nd of January 1870 I cut a fruit from it weighing almost 7 lbs. On the same date I cut a Smooth Cayenne 5½ lbs. weight, and sent them both to the dessert on the same day. When the seedling was cut, the juice flowed from it, covering the bottom of the plate as if a sauce had been poured over it. The Smooth Cayenne, in comparison with the seedling, was dry and juiceless. True, the latter grew in the row of plants next the outside of the bed, and probably had even less bottom heat than the seedling.

I may state that the dwarfest of the seedlings does not measure more than 12 inches in height, and it is expected to show fruit very soon; so that in one batch of seedlings we have the extreme of stature at least, showing that the Pine Apple from seed is as variable as any other fruit. So far as I am aware, the Pine Apple in a cultivated state seldom forms a perfect seed; but exceptions in this case as in all others occur now and then. The fruit the seed was taken from in this instance was a Montserrat grown by my predecessor here. Thirty-four varieties became strong enough to be pricked off, grown on, and fruited by the late Mr. Stevenson. The Montserrat fruit in question was cut in 1860, and was pronounced bad, or not in good condition, and when shown to Mr. Stevenson he discovered the seeds and sowed them. Many fruit of their first produce he sent to the London Fruit Committee. Of some of them favourable reports were given, but a good many of them were pronounced indifferent, while others were considered to be in cultivation before; but I do not think the Fruit Committee had a good chance of forming a fair decision, as the characters of the seedling produce were not fully developed, some of the fruit weighing only 1½ lb., and the heaviest 4¾ lbs. Some may consider that time has been lost in planting these a second time; but when all the leaves have to be sacrificed, and the stumps only kept to raise a clean stock, loss of time is accounted for. I hope to fruit more of these seedling varieties this season, when a little more about them may be made known.—J. Hunter, *Lambton Castle Gardens.*—(*The Gardener.*)

MASTER AND SERVANT.

Will you advise me as to the course pursued in the event of a gardener, who is a weekly servant, becoming ill and often unable to work? When able to work he is industrious. He is in a club, from which he receives 15*s.* weekly, and I have hitherto paid him his 22*s.* during his illness, adding 5*s.* to enable him to find an occasional labourer, but I am sorry to say this was but seldom. He is again ill with inflammation of the lungs—very ill, and, of course, cannot work for six weeks at least. I am a medical man, and so can give him all he requires; but shall I be doing a mean or unkind thing in providing what labour I feel necessary, and handing him over the surplus weekly? I am not rich, my garden being my only extravagance. What you advise I shall do. Again, he intimates that my work has caused him to be so often ill.

My garden is an acre and half, one-half kitchen garden, one-quarter lawn, with half a dozen small flower beds, the rest borders with shrubbery, &c. We have also a cow. My coachman is a handy man, and assists materially, and I do not look on. There is a greenhouse and small stove house. He is only a plain gardener, so there is no early growing of flowers. Is this too much for one man? If so, do I pay enough—22*s.* weekly? He has his tea in the kitchen, any vegetables, fruit, and milk not required, and a glass, or even two, of beer daily. If so, could I obtain a fairly good man able to grow a few ordinary flowers, as I adore them, in winter? I am not inclined to change unless he wishes it. Being a nervous, fidgetty being, must be the excuse of the one who signs—Spero.

[If you are not rich in this world's wealth, we may congratulate you on possessing the more enviable endowment of a kind, warm heart that can sympathise with the sorrows and afflictions of others. In one sense we are not at all surprised, for among all ranks and classes medical men stand separate and distinguished for their kindness and philanthropy. Alas! too often their self-sacrificing labours are apt to be forgotten when the affliction has passed away. Were there more of such kindly consideration as you evince, the late Judge Talfourd, if he were now alive, would not have to say that the great want in this England of ours was a want of seen and felt sympathy between all ranks and classes of the community.

On the whole, then, instead of giving you our advice, we would rather that you took the counsel of your own kind heart, and acted according to its promptings. A great many, however, are not able to do so; if they pay for labour, they must have the labour in return, and, therefore, without going to any extreme, we will allude to a few of the matters suggested by your letter.

1st. An acre and a half of ground, comprising half an acre of kitchen garden, a quarter of an acre of lawn, and a few flower beds, the rest in shrubbery, with a small greenhouse and flower stove, are quite enough for one man; too much if early things were desirable, not at all too much if fully the half were in shrubbery, needing little attention. All depends on what is wanted. There is an old saw about a man to an acre in a garden, but we have seen gardens in which a man to an acre would have little to do, and we have seen other gardens where, from flowers, forcing, &c., half a dozen men would be hard-worked.

2nd. As to the matter of assistance from coachman or groom, unless that is thoroughly understood and acted upon from the first, such help will generally be more found in the promise than in the performance, and what little we have seen would lead us to the conclusion that it is best to keep every department to itself. We are well aware that this cannot be done in many comfortable small establishments, but in such cases the coachman, groom, or others, should clearly understand they are to help the gardener. If that help is not to be depended on, it would be much better if the gardener had a boy or lad entirely under his own control. Unless the people in the stables have a zest for gardening, or know they must, as a matter of duty and service, give so much of their labour in the garden, our opinion is that all their labour and help would be of little value, and would be pretty well neutralised by the ill-feeling and the heart-burning fostered in consequence.

In many places of much greater extent, where several men are ostensibly employed in the garden, and the gardener has the name of having such a number of assistants, there is often infinite discouragement arising from the custom of taking men from the garden whenever they are wanted for anything about the house or the establishment—going errands, attending shooting parties, &c. It is a very common thing, if the gardener fall at all behind in his work, to be told, or rather to have it said of him when he is not present, that he has so many men, and yet in the most trying times he could not calculate on having half that number when he most needs them. Under such circumstances true economy and mutual satisfaction would be realised by keeping each department to its own separate duties.

3rd. We consider that the wages, with the other advantages mentioned, are very fair for the place, and more especially if lodgings are found. If not found, and flowers in winter were desirable, then we think a trifle more should be given to an industrious, clever man. We give this opinion more in consonance with the general verdict on such subjects than our own unbiassed ideas on the subject. For such small places good men may be obtained at from £1 per week, and many owners cannot afford to give more. But in this respect we hold the opinion of the late Mr. Loudon, that if the very most is to be made of a small place, you must get a first-rate man and pay him first-rate wages. In such a small place, to make the very most of it, he would have to work hard with his hands, and his brains, too, would be well exercised. In a large place, provided such a man were gifted with the faculties of order and organisation, he would have to work with his intellect more than with his hands.

4th When a man is at a distance from his own home it will be a great advantage to let him have his tea, and, if he likes it, a few glasses of beer, &c., on the premises, but, except in such circumstances, or when there is a stated allowance, it is best to make the payment entirely in money, and do away with all such allowances from the house. They often foster a kind of craving in some men, and lead them to be dissatisfied when actually they are well used.

5th. In the case of a weekly servant we do not suppose there is any legal claim upon you to pay wages when a man is unable to work, and more especially after a week's illness. We are glad to say that many in high positions act as you have done, from a kindly feeling rather than from anything like legal compulsion; many others, however, act quite differently. With them the rule absolute is, "No work, no pay," and we are sorry to say that there are cases that justify them in coming to such a conclusion. However, it is wisely ordered that kindness generally brings its own reward; and it should not be forgotten that what is a mere trifle to a wealthy man may be a matter of next to life and death to a poor man.

6th. We do not consider, in the circumstances, in attending to your afflicted gardener's medical wants, and other wants we have no doubt besides, that you would be doing "a mean or unkind thing," quite the reverse, if during his illness you found and paid for the necessary labour, and gave him the surplus weekly instead of his full wages. As already stated, this should be received as a matter of kindness rather than as a matter of right. We are a little in doubt as to your meaning, when, in speaking of paying your gardener his weekly wages when ill and adding 5*s.* to enable him to find an occasional labourer, you continue, "I am sorry to say this was but seldom." If the extra labourer was but seldom employed, then we would rather have our suspicions than express our thoughts.

Again, considering the way the gardener has been used in his illness, there is something rather repulsive in his intimating that "it is my work that has caused him to be so often ill." This may be merely the utterance of a morbid, melancholy feeling, the result of trouble and affliction; but no man with head and hands is required to stop in any place where the work is such as he knows to be ruinous to his health.

Lastly, knowing nothing of the circumstances but what you tell us, and hoping that your servant is too upright to be swayed by any unworthy considerations, still having the regular weekly wages in illness, and receiving a weekly allowance of 15*s.* from a club, would rather be a temptation in some men's way not to be in too great haste to be well and strong. It is sad to be obliged at times to look at the

dark side of poor human nature. Judging merely from what we have seen and known, we are not surprised that the managers of the best benefit clubs are careful that the money to be received in illness should be considerably less than what the members would receive as weekly wages; nor, again, have we been surprised that such managers have complained that some members when ill, and who from working to kind employers received a good part or the whole of their wages, as well as the allowance from the club, never seemed to be in a hurry to grow well. Alas! that there should be so much truth in this as to lead some benevolent employers to restrict their generosity in such cases, so that what they give and the allowance from the club may not exceed, or exceed but little, the usual weekly wages. True, "when a man is ill he needs more," but the scheming and the sponging often injure the truly deserving. In conclusion, then, every separate case should be judged on its own merits. We do not think you would act at all unkindly or meanly in adding so much to the club allowance, and paying for the necessary labour; but, as we said at first, we feel convinced your own heart will be your best adviser.—R. F.]

LEICESTER SQUARE FOR A FLOWER MARKET.

TO THE COMMISSIONERS OF THE METROPOLITAN BOARD OF WORKS.

GENTLEMEN,—Having seen in one of the papers that you contemplate taking under your direction and management what may justly be considered one of the metropolitan nuisances (I allude to Leicester Square), I, from my long and practical experience as a nurseryman and wholesale grower of florists' flowers, beg to submit for your consideration the appropriating of so eligible a situation to what is so much required and really wanted—namely, a metropolitan flower market.

I have attended Covent Garden as a florist regularly since the year 1836, during which time I have always considered that we were very much in want of a flower market, similar to those of our neighbours on the Continent, where nurserymen and florists might send for exhibition and sale their horticultural and floricultural productions; where ladies also would visit to select and purchase plants to decorate their balconies, flower boxes, and other modes for ornamenting their windows, &c. When considering the subject for more than twenty-five years past, it has been a matter of great surprise to me, and a very singular circumstance, that a spot so well suited for that purpose as Leicester Square, from its central position, should not have been appropriated to that purpose years ago; and I doubt not, gentlemen, but you will agree with me in considering the situation admirably adapted for that purpose.

Moreover, during my leisure hours of the long winter evenings, fully fifteen years ago, I amused myself by preparing a rough sketch of what I considered suitable, which represented a glass dome, in the centre, not more than 35 or 40 feet high. This I intended to be used as an aviary, a bazaar, winter garden, or promenade; and once or twice during the London season and summer to have a Rose or general flower show. By this arrangement I dispose of the surface or upper part of the space occupied by the dome, under which I would remove the whole of the soil to the depth of 9 or 10 feet, which space might be used for cellars, or used, as the French people do the caverns round Paris, for the culture of Mushrooms; and, if so used, I am confident it would soon be rented to advantage.

Having disposed of the centre, my arrangement for the disposal of the outside frontage of the square, according to my rough plan, would be as follows:—To appropriate the whole to a series of ornamental shops similar to those in the Grand Row, Covent Garden Market. Over each I would have one or two sleeping rooms, with a good kitchen in the basement; and in front of the shop alluded to I would have a space covered by a glass roof of from 150 to 200 or more superficial feet; this should be heated by hot water, or some other mode, and connected with the shop, to be used as a place to exhibit floral subjects for sale. It would not be necessary to have these glass erections more than 12 or 15 feet high, but they should extend to the very outside boundary, and completely encircle the market, and if tastefully designed would be interesting objects to look upon from the adjoining houses surrounding the square.

These glass erections I intended to be used not only by the florists and nurserymen in the vicinity of London, but by those residing within a circle of 20 or 30 miles of London, who, I doubt not, if these erections were let at a moderate rent, would gladly avail themselves of this depôt for the exhibition and sale of their arboricultural, horticultural, and floricultural productions; as it has been, and is, in my opinion, a great and serious loss to all country nurserymen and florists living at a great distance from London, who might be the introducers of new species or varieties of horticultural and floricultural subjects, that they have not a place in or near London where they may perpetually exhibit their valuable novelties, and where the botanist, florist, naturalist, and amateur may see and admire the wonderful works of the great Creator manifested in the vegetable kingdom.—J. W. THOMSON, F.R.H.S., *Florist, Penge.*

WEATHER PREDICTIONS.

I TRUST your correspondent, Mr. Robson, will pardon me if I point out that he has made several important mistakes in his letter on page 101. If he had not made these mistakes he would have found that the Linton Park observations were not "all at variance" with the theory I "promulgated."

1. Your correspondent has not taken the Linton Park or the "Greenwich mean temperature of August to October" into due consideration.

2. He has omitted to notice that there is an important difference between the mean rainfall of Linton Park and that of Greenwich during the first seven months of the year. This difference renders it necessary to raise the limit from 10 inches to about 10½ inches when applying my law to past years at the former station.

3. If your correspondent had carefully read the letter of "AMATEUR," at page 85, or my letter in the valuable "Meteorological Magazine" referred to, he would have seen that I explained what I meant by the expression, "a remarkably severe winter." I said, "That is, the mean temperature must be very considerably below the average." In this respect the winter of 1866-7, as well as that of 1860-61, was not very severe. In the winter of 1866-7 the mean temperature of December to February inclusive at Greenwich was more than 2½° above the average of ninety-nine years, and January to March inclusive 0°.4 above the average. Mr. Robson must therefore allow me to say that he is remarkably inaccurate in speaking of that winter in connection with my law, as "exceedingly severe."

4. Mr. Robson's assertion that I used the word "probably" in connection with my prediction of the winter of 1870-71 is incorrect. I spoke with certainty. I said that "it must be remarkably severe." A law which has never failed in a hundred years at Greenwich justifies this positive form of prediction. For many years past I have, with the aid of apparently infallible laws, been able to predict the summer as well as the winter seasons. In a paper read before the Meteorological Society in April last I stated a law, according to which the summer of 1870 should be warm, and on the 13th of May last I predicted in a local paper that the "coming season must be a good one." I also stated that the summer would certainly be fine. I commenced predicting summer and winter seasons in 1864, and since that time have not had one failure with regard to them. These facts show that "line of investigation" referred to by your correspondent, "AMATEUR," has been followed up for seven years, and they prove (in opposition to the statement of Mr. Robson) that, as far as summer and winter seasons are concerned, there is no uncertainty in my weather predictions.—GEORGE D. BRUMHAM, *Barnsbury.*

FAILURE OF VERBENA CUTTINGS.

I HAVE been much interested in the correspondence in the late numbers of your Journal about Verbena cuttings, and I wish to endorse the opinion of your correspondent that there has been some unusual disease prevalent amongst them this season.

I am generally successful with Verbenas. Last summer mine were the admiration of all beholders, but I fear I shall have no show at all this year. The cuttings rooted, and I potted them off as usual, but one after another they blacken and die. I have now put all the survivors into a nice fresh hotbed, supposing the failure to be owing to the unusually low temperature for the last three months. They do not seem to be much the better of the change at present. The healthy ones (chiefly Lord Raglan and the commonest kinds) are growing, of course, but the sick ones get worse and worse, and will evidently die.

In this mild climate (Pembrokeshire) Verbenas have lived with us in the open air all the winter, year after year; but, alas! these happy seasons for our half-hardy favourites seem now like grandmothers' tales of the good old times that used to be "once on a time" long ago.—C. J. S.

[I hope before this reaches "C. J. S." that a change for the better will have taken place in the Verbena plants, which may still be reviving; and, as there is a good deal of time yet for propagation, that she will be able to make up her stock to the quantity wanted. If it be any consolation for her to know it, I may say there seems to be a very general complaint of Verbenas having kept badly this winter, and inquiries for cuttings are made in all directions. The cause is, no doubt, what "C. J. S." justly assigns—viz., the low temperature, and, in addition, the want of sunshine; for during the greater part of both December and January, and of February up to the present time, the sky has been almost entirely sunless; even the sharp frosty days were mostly dull, and forcing has only been accomplished at a great expense of fuel. In keeping Verbenas through this dark period I have, however, never been more successful than during the present season, only we do not grow these former favourites of the flower garden so extensively as some do, and have not so many kinds, chiefly confining our growth to three or four varieties. Nevertheless, I have others, and they have all kept well, only they have had a better position than they have sometimes had in former years, for this season I had an opportunity of giving them a place close to the glass on two shelves at the back of a vinery, which was kept a little warmer than an ordinary greenhouse, and this elevated position, where

the air could circulate on all sides of them, no doubt enabled them to withstand the destructive influence of the long dark period we have just passed through. Had they been, as usual, wintered in a cold frame, with only coverings to keep out the frost, most likely I should have had to bewail the loss of the whole, for I find the Geraniums in boxes, which are here far more important than Verbenas, have kept much worse than usual, owing to the dull weather and limited heat supplied. I have long been of opinion that to keep Verbenas well they must be kept growing, for it is no easy matter to start them when once they become fairly stunted and diseased.

My mode of managing them is usually to take off cuttings from the middle to the end of August, and to strike them in some shady place without heat, so as not to encourage too much growth at top. I also use larger pots than most people; the size called sixteens in the trade is that which I generally adopt, and the cuttings remain in the pots all winter, yielding successive batches of cuttings if all go on well, but I have often been unfortunate and lost a great many, especially when the pots have had to stand some time on the ground in a cold pit, where both heat and a good circulation of air have been wanting. Now, although Gazanias and, I believe, Nierembergias will endure this with impunity, and, in fact, may be covered up for weeks, as some of mine have been, Verbenas will not. Warmth and a free circulation of air are necessary for them, and what is also equally important, insects of all kinds must be kept down, and however clean and healthy the plants may appear at the time cuttings are taken off for propagation in early spring, we nevertheless immerse them in a sort of decoction of tobacco about the colour of porter. Immersion for a couple of minutes or so will destroy any green fly that may be remaining, and does the cutting no harm. A basin or other vessel of this liquid always accompanies those putting in spring cuttings. The first lot of cuttings was put in on February 6th; at this season they are mostly put in in boxes—at least all the kinds propagated to any extent, and a four-light frameful of such cuttings, after they have been in a week, all look like growing, the heating material being merely a mixture of dung and leaves.

I have often been short of plants to propagate from at this season, and our present ample supply is mainly owing to the winter stock having had a more favoured position than usual during the dark days. If I had only a few plants, and wanted to increase them to the greatest possible extent before planting-out time, I would prepare a nice, warm, dung hotbed, with suitable soil in it, as if for Cucumbers, and after having dipped the Verbena plants in the tobacco water previously described, I would turn them out of their pots into this bed, not disturbing the ball if it could be avoided, and allowing the plants to grow till they completely covered the bed before taking off any cuttings; then any reasonable quantity could be had, for I believe much harm is done by cutting a plant too early, and where the root has room to grow the top ought to be allowed to do so also. This I fear is not in the power of "C. J. S." to do, but I advise the bath nevertheless, a warm site if it can be had, and if the plants are in small pots, a few of the best might be shifted into larger ones, and growth will likely follow; at the same time do not remove all the soil from the roots, otherwise time is lost, but repot the ball entire, even if there are a great number of plants together, and success may yet reward the labour.

Much has been said on the wintering of plants for the flower garden, and the various modes adopted for the purpose; there are, nevertheless, plants which can only be kept over winter with a much greater amount of means than most amateurs have at command. In August beds of Coleus look well, and are deservedly admired, but the plants are not easily kept over the winter without a structure approaching a plant stove in heat; Alternantheras are still more difficult to keep in a cool place; in fact, they are usually miserable-looking objects in January, and many are lost. Fortunately both they and Coleuses can be rapidly propagated in spring, and as neither are wanted very early, their propagation may be carried on later in the season than that of the Verbena and similar plants. I have sometimes thought of writing an article on keeping bedding plants in winter, commencing with those which endure the greatest amount of cold, and going gradually upwards to such as require the greatest amount of heat; if I did so, I would place Verbenas in a warmer temperature than they often receive, for although I have frequently taken cuttings in spring from plants that have stood out all winter, I have often lost cuttings in a way that I could not account for, except on the ground of absence of light, heat, and fresh air. With disease, excepting mildew, I have not been much troubled; nevertheless, the failures of Verbenas towards the end of August, in dry summers, have been so frequent that I grow comparatively few of them.

In closing these remarks on this once popular plant, I would ask the reason why it affords a much shorter continuance of display than it did twenty years ago, when such old kinds as Emma, Atrosanguinea, Tweediana, Beauté Suprême, and others might be reckoned on as sure to last the whole season? The failure of Verbenas to do so has led me to very much limit the number planted, and a visit to any public or private garden of importance reveals the fact that this once-popular flower no longer holds the place it did, and something more than the difficulty in wintering it is the cause.—J. Robson.]

WONDERS OF AN AMATEUR.

I wonder if the proposition laid down in two recent numbers of one of your contemporaries (*apropos* of Camellias) is a correct one—namely, that peat and loam mixed together in a pot, become, after a certain time, injurious to the plant contained in it, by the action of the acid in the former upon the alkali in the latter. If so, the authorities on such matters, from Paxton down to the editors of the "Gardeners' Dictionary," have been but "blind guides." In the fourth vol. of "Paxton's Magazine," 1838, which I took up by chance this evening, I see that, of the plants which are represented in the first nine coloured plates, we are advised to grow no less than six in a mixture of "peat and loam," and in the "Gardeners' Dictionary," published exactly thirty years later, of the first nine plants of which the culture is described in detail, we have the same obnoxious mixture recommended to us in five cases. With such authorities a humble amateur cannot at once imbibe the new theory, while at the same time the extreme and undeniable difficulty of growing Camellias makes me grasp at any explanation of my failure.

I wonder why the use of the pot saucer in watering plants in pots is not more insisted upon in gardening manuals. I look upon it as not only a useful, but an indispensable adjunct, and especially for two classes of plants—1st, bulbs, which are started in dampish soil, and are not watered again till their shoots appear, such as most of the Iridaceous tribe; and 2nd, succulents, which are kept almost dry from October till February or March. The soil of the pots which contain plants of these two classes, can never be so rapidly or satisfactorily saturated as by the use of the saucer. It seems only reasonable, too, that plants which are dried by the action of the flue in a conservatory should receive moisture at the end of the pot which is nearest the source of heat, and I venture to say that anyone who examines the bottoms of pots which stand over or near the flue will find, especially after the great amount of fire heat which this season has occasioned, that the lower portion of the soil where the young roots should be is nearly dust dry, while the upper inch or two of the soil is saturated with water, and perhaps sour and covered with moss. The same principle which induces us to water pots from the top when standing out of doors, below the source of heat, should direct us to water from the bottom when the pots stand above the heating medium. Moreover, a certain tribe of plants which grow on hills, such as Primulas, Auriculas, and Calceolarias, even in their natural state, what with melting snow and mountain streams, derive at least as much moisture from below as from above.

I wonder, too, at many other things, but, being a man of business, I have no more time to spend in writing down my wonders.—Rush.

NOTES MADE DURING A TOUR IN IRELAND.

No. 6.

ROCKVILLE, THE SEAT OF THOMAS BEWLEY, ESQ.

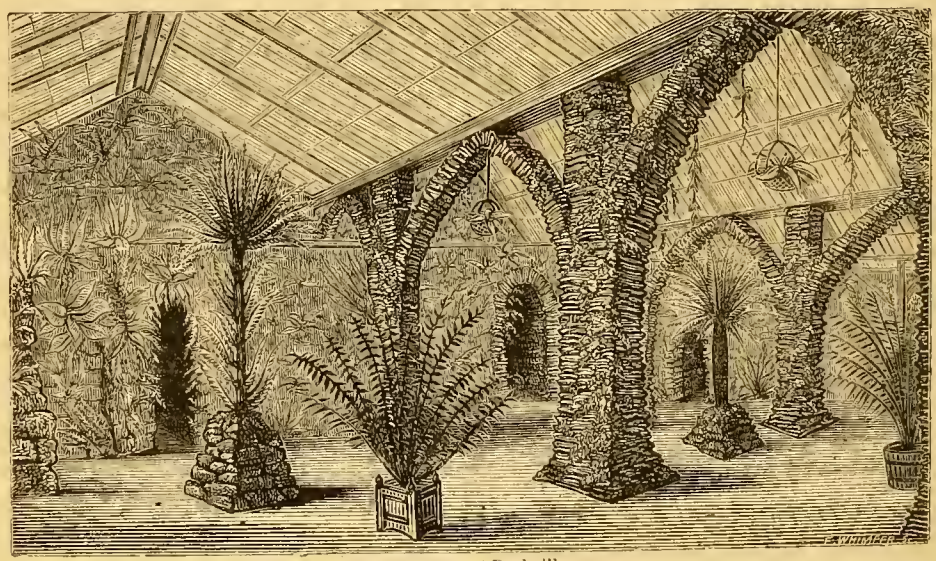
The splendid service of mail steamboats from Holyhead for Dublin land all their passengers at Kingstown, the pretty and fashionable Irish seaport, whence they are conveyed by rail to Dublin—a distance of ten or twelve miles—through a lovely country. Landing at Kingstown, one is very favourably impressed with the beauties of Ireland; all along the line of railway there is the beautiful Bay of Dublin, one of the most glorious that can be imagined, bounded in the distance by Hove and the craggy rocky promontory called Ireland's Eye, and every now and then we catch a glimpse of Dublin herself lying placidly sleeping in her misty shrond, with here and there a tall chimney or a church tower peeping forth. On the other side of the line lies a beautiful country, richly clad, finely

wooded, and studded with numerous pretty villas and well-kept gardens. Here, I fancied, as I sped along, will be found the retreat of many of Dublin's rich citizens, and gardening will be found flourishing. Whilst I was musing thus, the train slackened speed a little on nearing the first station. Is it Blackrock? Yes, Blackrock, where resides, as I was very shortly informed by my friend Mr. Robertson, the great Mr. Bewley in his world-famous gardens. To return to Blackrock was, therefore, one of my first duties. Taking advantage of a friendly car at the station, the distance—about a mile—of rather uphill road was soon traversed, and I was at the garden gates.

There is at first sight nothing at all imposing in the appearance of this place. Close to the public road stands Mr. Bewley's residence, having in the front an open space of grass, with numerous beds tastefully formed and well filled with the usual bedding materials. This is bounded on two sides by ranges of hothouses, giving it a very circumscribed appearance. The extent of the place is altogether very limited, yet it is rich and full of interest. In every nook and every corner there is something worth seeing; the extent of glass houses is very great, and some are of very fine construction.

Mr. Sayers, the very intelligent gardener, being on my arrival engaged in showing a company of Irish belles his treasures, I had time to cursorily survey the exteriors of the various buildings, the doors being all securely fastened, and to note some of the arrangements of the ribbon borders, &c. One border, alongside what was once the orchard house, was planted as follows, and I thought it looked very effective. Line 1, Cerastium Biebersteini; 2, Pelargonium Golden Chain; 3, Iresine Herbstii; 4, Pelargonium Flower of Spring; 5, Purple King Verbena; 6, Pelargonium Rose Queen; 7, Centaurea candidissima; 8, Pelargonium Stella, with a tall backing. I was here again much pleased with several beds of Pelargonium Amy Hogg, the colour of which in the mass was most charming.

Mr. Bewley has been a great experimental horticulturist. It was at his establishment where the system of double-glazing the roofs of hothouses was first tried on a large scale. Greatly applauded and recommended as it was for a time, like many other new things, it is now condemned and almost forgotten. Even at Blackrock little can be said for it. Here, also, were erected the grandest of orchard houses, lofty span-roofed houses, where the trees—Peaches, Pears, &c.—were planted out and had to grow as in the ordinary open-air orchard; but success was not attendant, and most of the fruit trees have been removed. Vines still cover a portion of the roof. The Pear trees planted in another portion of the garden were laden with fine fruit. The orchard houses still exist at Blackrock, fine, noble, span-roofed houses, two of them, about 60 feet long, joined to either side of a broad span-roofed plant-house; but they are directed now to another use besides fruit-growing—that of ornamental plant-houses, for which purpose they are much better adapted. As orchard houses they were far too dark and heavy, fruit trees requiring as much light and air as can be given. The middle house of this group had a beautiful ground-covering of Selaginella, with a winding path from one end to the other, leading to the great fernery. In it were many fine plants, lofty tree Ferns, a very fine Theophrasta 10 feet high, a Dragon's Blood, and some groups of fine-foliaged Begonias, a large Fan Palm, &c.



The Fernery at Rockville.

Passing out through some low, narrow, dark rustic passages, I entered the great fernery, the fame of which has spread far and near. There is no question about the grandeur and magnificence of this house. It is a great square place, 60 feet by 48, covered with a double-glazed glass roof about 10 feet high to the bottom of the ridges, there being five spans or ridges in all, supported on columns enclosed in pillars of rustic stonework and rustic Gothic arches mantled and draped with Ferns, Mosses, and the coloured-leaved Begonias, the sides being draped in the same way, so that it looks like a great rustic cavern. In intermediate lines with these supporting pillars are placed tall specimen tree Ferns of majestic character, grouped round their base with smaller varieties in rustic style. The appearance of the whole is very grand but very sombre, rather too much so for showing off the graceful forms of many of the beautiful Ferns. It impresses one with a certain feeling of awe, as when inspecting the ruins of a great abbey, to which, indeed, this fernery may not inaptly be likened. At one end there is a rustic stone staircase giving access to a high pathway along the end, whence one can look down upon the lovely scene, and from which the tree Ferns are seen to great advantage. It is beautiful to look up at a majestic Fern; it is much more so to look down into one and to observe the uncoiling of the young fronds. The arrangement of the house is simple yet noble; there is little crowding, and everywhere the Ferns are growing in the wildest luxuriance. To enumerate, or to give any idea of the character or number of the noble plants is next to impossible. The tree Ferns are wonderfully fine—Cyathea medullaris, with a 12-feet stem and fronds 8 feet long; Cyathea dealbata as large; Cibotium princeps, 12-feet stem, very beautiful; Dicksonia squarrosa, the various Alsophilas, &c. Shining like silver amongst the dark green of the various Fern fronds stood out the beautiful leaves of the Begonias of the Rex type. This served to lighten up the whole, and created a pretty feature. It is wonderful how well these Begonias succeed planted amongst Ferns on rustic stonework. Never have I seen them look so finely as where planted in this way at Rockville. Along the roof of this magnificent fernery rambled Hoya carnosa, flowering in the greatest luxuriance in all its chaste and waxy loveliness.

There are a great many other houses full of interesting plants, as Ferns, numerous Orchids in fair condition, fine-foliaged stove plants, Palms, &c., to which I can make no more than a passing allusion, but giving Mr. Sayers a world of care, and being very creditable to him. There is too much glass for the size of the place, requiring too great an expendi-

ture to maintain it. There are traces here and there of faded grandeur, as if at one time more means had been at command to keep the wheels moving. Nevertheless, the fernery at Blackrock is alone worth a journey to Ireland to see it as it now is.

In open-air gardening, besides the summer bedding plants already noted, which are to be found everywhere now, there are several quaint rustic walks near the boundary walls of the garden, the inner side being formed of a series of rustic stone Gothic arches like the sides of a railway; from these other rustic arches are thrown across the path to the wall at every 10 or 20 feet. The idea is pretty good, but as carried out it is scarcely bold enough in character to prevent it from being called "toy." These stones and arches, however, are the abiding place of a fine collection of British Ferns, not, perhaps, so much a collection of varieties as in number, and they looked well. Here, also, the Bamboo seemed to do well, and was particularly striking in character.

In another detached small garden were the fruit trees—the very trees, as I was informed, of Apples and Pears which had formerly been planted in the orchard houses. A line of fine pyramid Pears on Quince stocks, 8 feet or so in height, planted only 6 feet apart, were bearing very heavy crops of fine fruit. I observed Duchesse d'Angoulême, Glou Morçeau, Chaumontel, Louise Bonne of Jersey, and Marie Louise, as fine as ever I have seen them anywhere. Apples also were unusually fine, the crops immense on very little trees, conclusively showing that, if attention were given, Ireland could become one of the finest of fruit-growing countries.—B.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

Amaryllis Rayneri (Rayner's Amaryllis). *Nat. ord.*, Amaryllidaceæ. *Linn.*, Hexandria Monogynia.—Native of Brazil. Flowers lilac; leaves broad, sickle-shaped, and buff-edged.—(*Bot. Mag.*, *t.* 5883.)

Gladiolus dracocephalus (Dragon-headed Gladiolus). *Nat. ord.*, Iridaceæ. *Linn.*, Triandria Monogynia.—Native of western Natal, at the foot of the Drachenberg Mountains. Flowers lurid green, with lines of dull purple.—(*Ibid.*, *t.* 5884.)

Cirsium Grahami (Graham's Cirsium). *Nat. ord*, Compositæ. *Linn.*, Syngenesia æqualis.—Native of low valleys in New Mexico. Flowers bright crimson.—(*Ibid.*, *t.* 5885.)

Pogogyne Douglasii (Douglas's Pogogyne). *Nat. ord.*, Labiatæ. *Linn.*, Didynamia Angiospermia.—Native of California. Flowers purple, white-spotted.—(*Ibid.*, *t.* 5886.)

Cyrtanthera chrysostephana (Golden-crowned Cyrtanthera). *Nat. ord*, Acanthaceæ. *Linn.*, Diandria Monogynia.—Native of Mexico. "The flowers, instead of being disposed in a dense thyrsus, or in axillary cymes, as in most species of the genus, are collected into a crown-like corymb at the tips of the branches, and are of a bright golden yellow."—(*Ibid*, *t.* 5887.)

Double Tiger Lily.—"This beautiful plant has the habit of the old, well-known, and popular Tiger Lily, L. tigrinum, but is abundantly distinct from it as a garden flower on account of its double blossoms. The stems, which reach 3 feet high or upwards, are furnished with a thin covering of white cobwebby hairs, and clothed with numerous scattered lanceolate leaves, the lower of which are 4 to 6 inches long, the upper ones shorter and broader, and bearing the usual black shining bulbils in their axils. The flowers form a fine spreading panicle at the top of the stem, but in the smaller and weaker specimens the stem was surmounted by only a couple of flowers. In this respect the variety quite resembles its type, the weaker bulbs produce one or two-flowered stems, the stronger ones a panicle of numerous flowers, varying in number according to the degree of vigour. The individual flowers are about 4 inches across; but instead of the leaves of the perianth forming a single series, as in the ordinary Tiger Lily, there are in this double-flowered variety no fewer than six series of petaline segments, which, for the most part, are opposite, and lie over each other in their recurved position like the petals of the hexangular Camellias. The colour is a bright orange, densely spotted with blackish-purple spots.

"We are indebted to G. F. Wilson, Esq., of Weybridge, for the specimen figured, and which was exhibited by him on the 3rd of August last, at a meeting of the Royal Horticultural Society, when it received a first-class certificate. The bulbs were, we believe, imported from Japan by Mr. Bull.

"There are some other remarkably fine varieties of the Tiger Lily worthy of especial notice. One of these is the L. tigrinum Fortunei, introduced by Mr. Fortune from China, and cultivated by Messrs. Standish & Co. This is remarkable for its vigorous growth, and its immense head of flowers, which branches out in three successive series from the main stem, by which the blooming season is much prolonged. Another is the L. tigrinum splendens, introduced to public notice by M. Van Houtte, and which in its taller stature and ample branching inflorescence bears considerable resemblance to the var. Fortunei; but is said to differ somewhat in colour, and in the fewer and more prominent spots on the perianth. Both are grand additions to the group of hardy bulbous plants."—(*Florist and Pomologist*, 3 s., iv. 25.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

Asparagus, make new beds with two-year-old plants, and fill up old beds. Plant out Mazagan *Beans* from boxes and pots; sow Long-pods. Plant out *Cauliflowers* from the frames or hand-glasses, the latter to have three or four left in each. Make a small sowing of *Celery* on a warm border. Sow *Leeks* for a principal crop. About the second week in March is an excellent time to sow the main crop of *Onions*. One of the prime objects in Onion cultivation ought to be to secure an early harvest, and this is best accomplished by elevated beds unmanured, unless the soil is very poor. The land should be selected in November, generally a plot which has had one scourging crop taken off after a good manuring. It is trenched and ridged until the early part of March, when, being levelled down, it is marked out into beds 42 inches wide, with 15-inch alleys. Before the seed is sown the beds are raised 6 inches above the ordinary ground level. When the beds have become dry the seed is sown, and they are trodden twice over until they are quite hard. A very light coating of soil is then strewed evenly over the whole. The narrowness of the beds enables the operator to weed clean with facility, and without injuring the plants. I have found that hoeing, by loosening the surface, exposes the Onions to the mercy of every storm, and if luxuriant throws them prostrate on the surface. Plants thus situated, having a greater depth of soil than usual, grow with a more sturdy character than those in highly-manured ground, whilst the elevation of the beds enables the warm July sun to penetrate a considerable depth into the earth, slightly checking late growth, and, of course, inducing the early formation of bulbs. *Pot Herbs* should now be sown, or plantations made from cuttings. Plant early sorts of *Potatoes* in a warm situation for earlier crops; a few may be first planted in boxes in heat, and transplanted to the open ground when they have vegetated. Those growing in frames should have air given freely. Sow *Savoys* for an early crop.

FRUIT GARDEN.

Proceed with pruning and nailing. If any planting still remains to be done, let it be performed as soon as the ground is in a fit state. Do not, as is sometimes done, over-manure; it is a great mistake to induce the production of gross, long-jointed wood in any stage of the existence of a fruit tree; wood of this description never becomes thoroughly ripened, and in the case of stone fruits, gum, canker, and premature death are sometimes the result, whilst from Pears anything deserving the name of a crop is never obtained till the gross habit induced by planting in over-rich soil is overcome. Ground intended for fruit trees should first be drained efficiently, and then trenched to the depth of 2 feet, and if the natural soil is found to be too poor for the health and growth of the trees, a sufficient quantity of fresh turfy loam should be added, but rich stimulating manures should not be used, for they are soon exhausted, and the trees are left to depend upon the natural soil for their support, and when treated in this way never give satisfaction.

FLOWER GARDEN.

Bourbon, Tea, and other tender Roses must not be disturbed for the present, but as soon as the weather has become more favourable let them be pruned, and the beds be manured and lightly forked. Roses, however, do not dislike a rather firm soil, and care should be taken not to injure their roots by forking or digging too much. The best manure for them is well-rotted cow dung which should be applied after carefully loosening the soil, and an inch or two of fresh mould sprinkled over it will obviate any unpleasant appearance it might otherwise present if kept near the surface. Auriculas, generally speaking, have suffered little from the past severe winter, and having braved the weather so well hitherto it would be a matter of regret should any collection suffer from lack of a little at-

tention at this season. As they are now beginning to grow and to throw up their trusses, they require the greatest attention of the cultivator; they must have plenty of air, be moderately supplied with moisture, and protected at night from the slightest frost or cold easterly winds, when the lights must be tilted the reverse way, so that the plants may not receive the least check in their growth. On the contrary, if the weather be mild they require all the air it is possible to give them. A gentle shower of rain once now and then is of great benefit. About a fortnight after the roots of the Ranunculuses are planted, they swell to their utmost size. While in this state, in the event of severe frost setting in, it is advisable to cover the beds with some dry litter to the depth of 3 or 4 inches, as the tubers are liable to be ruptured by the compression of the frozen soil. In the best prepared beds worms are very annoying and injurious, particularly in March. Lime water may be given with safety; apply it to their workings in the morning, and fill up the cavities in the surface of the beds with dry soil, which ought to be kept in reserve for the purpose. In the first week of April the plants will be through the ground. The strong-growing sorts are sure to lift a large portion of soil on the top of their foliage; let this be taken in the hand, broken, and carefully placed on the top of the crowns and about the necks of the plants. Should the grower wish his flowers to be of a good size, a top-dressing of three-year-old cow dung finely sifted may be applied round the plants and between the rows to the thickness of one-fourth of an inch; this has a most beneficial effect in keeping the beds level, and increasing the strength of the plants. Polyanthuses in beds that have been raised by the late frosts should be fastened, and a top-dressing of rich vegetable mould given.

GREENHOUSE AND CONSERVATORY.

A general dressing of the climbers should take place immediately. When it is desirable that they should bloom late in the autumn it will be advisable to prune late, even after the buds have commenced growing, on the same principle that the Moss and other Roses are successfully retarded by a similar proceeding. Fuchsias for general decoration, or as single specimens on grass, should be brought forth and introduced, if there be room, in a warm end of the greenhouse. Those who have bottom heat to spare, and desire very large specimens, may select some of the best plants, disroot and repot them, and plunge them in a bottom heat of 75°. A good compost to grow them in is two parts decayed leaf mould or peat earth, one part rich yellow loam, and one part horse and cow manure in equal quantities, with sufficient silver sand to sharpen it. The Hybrid Perpetual, Bourbon, Tea, and other Roses will now begin to repay by their beauty the trouble bestowed on them. Give weak and clear liquid manure more freely, disbud barren shoots, and fumigate early. Some of the forward Cinerarias and Pelargoniums may be shifted as requisite, as soon as the blooming habit is sufficiently brought on; if done sooner, a superabundance of foliage will be the result.

STOVE.

Some of the plants which have been blooming for many weeks, and which are exhausted, should be cut back and removed to a moderate house to break slowly, such as the Euphorbia jacquiniæflora, Gesnera lateritia, Geissomeria longiflora, Eranthemum pulchellum, Justicia salicina, Poinsettia pulcherrima, and others. These, although not very novel, are very useful, and their early flowering next November and December depends on early cultivation. A bottom heat will be necessary when they are repotted, which will be in about three weeks.

FORCING PIT.

See that all Hyacinths, Roses, Lilacs, Narcissuses, or, in fact, any other forced flowers, are removed from the forcing pit the moment the blossoms begin to expand. Retarding will soon be every-day business.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

AFTER the frost alluded to last week we have had some favourable days for out-door work. Never did we know the soil turn up so freely, and be so dry at this season of the year. If there is no great change as respects moisture, there will be plenty of March dust this year for the comfortable depositing of the seeds.

The general routine was very much the same as in the last and previous weeks. We put in a good breadth of Peas and Beans, trenched the ground, and re-dug and turned that intended for Onions and Carrots. The Celery beds were trenched across, so that the dung left in the beds should be regularly distributed across the quarter. With a little covering in the most severe frost our Celery is still very nice, and turns out well. The late-planted is rather small but sound. We never planted Celery so late as last season. It stood quite thickly in the beds in which it was pricked out, as there we could give a little water and shade. We could not have kept it alive if transferred to wide beds or trenches. We could only manage to preserve our earliest, and therefore strongest, Celery by shading. Notwithstanding all this contest with the drought, we have not had a single bolted or bad stick of Celery this season. We attribute this a good deal to the mode of treatment, and especially to the manner of earthing-up several times referred to. If we have done nothing else, we believe that we have proved conclusively that the bit-by-bit earthing-up of early Celery is the chief cause of its bolting, and thus becoming unfit for table.

Potatoes.—Besides planting under protection, the ground was in a fine state for putting in some of the earliest out of doors, the tubers being just sprung nicely, but not too much. If planted fully 6 inches deep there would be little danger from frost, and there would not be much earthing-up required.

Besides planting stout *Lettuce* plants in the orchard house, we have turned out some thinly between the rows of Potatoes in frames that have been planted out lately, after being just started in pots. We hope the Lettuces will attain a good size before the Potato tops interfere with them. In such early Potatoes, nipping out the terminal bud of the shoot when a foot or so in height prevents elongation, makes the shoots more stubby with laterals, and does not interfere with early tubering. Most of our Lettuces out of doors on the level, though protected, like our fine Cabbages in the open quarters, have given way before the cold, whilst Lettuces on ridges, which measure say a yard at the base, with a yard slope on each side, east and west, have stood well. The Cabbages that have stood best, as already alluded to, are on ridges, and facing the north. There is little new in this—the less vigour there is in a plant the more frost it will stand uninjured. We are often wise behindhand. We have frequently gone over our forward Cabbages at the end of October, and raised them with a spade or fork sufficiently to disturb the roots, and then trodden firmly. The check thus given was a great security against severe frost. We did not do so this season, or very probably we might have saved more of our fine plants. We shall, however, soon turn out a lot forwarded in pots. We shall be obliged to do so as a matter of safety, as they will not be such tempting baits to mice, &c., when they are in the open air. Even though we put a cordon of tar round a frame, we find the mice passed it, and made sad havoc of a lot of bulbs inside. Well would it be for gardeners to cultivate patience as well as increased constant watchfulness.

FRUIT GARDEN.

Here we can add little or nothing to the notices lately given, as from a press of other work out-door pruning, &c., has fallen a little behind, but there is nothing in that respect too late as yet, as there is no appearance of the sap moving. See what was lately said of Peaches, Vines, Strawberries, &c.

We potted off young Melon plants, as at present they occupy small space, and we may find room for them before the plants are large. Potted off also young *Cucumber* plants, and turned strong young plants into 15-inch pots to produce fruit. In our small pit the old plants are still producing a few fruit, and some of them appear likely to go on if we do not work them too hard. If they stand until the younger ones bear we shall be satisfied.

Though this is not, perhaps, the right department to treat on Cucumbers, we may here state that many readers have asked us how we afford our Cucumber plants so little root room. Well, simply because we want a large quantity of Cucumbers in little room, and not strong shoots and parasol-like foliage. These are all right enough, and productive enough, too, if one can give the plants a roof of 12 or more feet to run over; but in a frame or pit of 6 feet or less in width the plants should be curbed rather than encouraged in their luxuriance. Our little pit is scarcely 6 feet wide, inside measure. There is a narrow pathway behind, and the bed or pit for the Cucumbers is not quite 3 feet wide, with two 3-inch pipes in front, and two beneath for bottom heat. Even this narrow bed, for such a limited space, we find quite large enough for root room, and therefore we often plant in pots, as stated above, and surround

the pots with hot tree leaves, keeping the top of the ball several inches from the rim of the pot, earthing-up at times until the pot is full, and earthing the bed over with rich light compost, and allowing the roots to run over it. Last summer and autumn the bed had, perhaps, about half an inch of rich top-dressing added every month or so. We have found no plan better for keeping up a moderate luxuriance and great fertility in little space. Just as the fine large white roots began to appear on the surface, a little fresh rich compost was sprinkled over them, but what was alluded to last week, as to the matter of checks, was carefully attended to. Putting fresh cold soil to a plant in a high temperature is often followed by baneful results. Were the principle involved in sudden and severe checks better understood, there would be less sale for insecticides and other destroyers of insect vermin.

ORNAMENTAL DEPARTMENT.

Here our chief work has been, and will be for some time, ground work and turfing. We shall be anxious to have such work over by the middle of March at furthest, as then we may expect to be little troubled with the turf in summer. There is much trouble in getting extra men, who never took up or laid a piece of turf in their lives before, to do so at all neatly. Much depends on taking up the turf in equal widths, and at equal depths, and then with a line marking the levels it is not so easy to go wrong. Two lads, who had never handled a sod before, turfed a piece very neatly the other day. We hope that in a few weeks general labourers' work will be more plentiful.

Referring to general matters, we will just allude to two things requiring timely attention. For *sowing the seeds of tender and half-hardy plants*, a hothouse or a hotbed will be necessary, and a bottom heat of from 80° to 90° for the first, and from 65° to 75° for the second. All seeds do best in general in rather light sandy soil, enriched with a little leaf mould that has been well sweetened and aired. A little small charcoal will also be an advantage. With large seeds there need be no difficulty, provided they are covered with about their own diameter in depth of soil. Smaller seeds require more attention, and especially such dust-like seeds as those of the Lobelia and Calceolaria. It is best to use as little water to such seeds as possible. We generally, therefore, drain and fill the pots within an inch or so of the rim, using the roughest soil over the drainage, rough but finer over that, and finer at the surface, pressing moderately down with a board; and then the soil in the pots is well watered, and allowed to stand from ten to twenty-four hours, so that the surface may become somewhat dry; on this the seed is scattered, and a little fine silver sand, or silver sand and charcoal dust, sprinkled as thinly as possible over the seed, and gently pressed down. If a square of glass with a piece of paper or cloth is put over the mouth of each pot, there will be next to the certainty of attaining success, keeping the shade on until the seedlings begin to show, and then removing the shade by degrees. The damp in the pots beneath the seed will generally be sufficient to cause germination, without watering, but when watering is necessary it should be given by gently sailing the surface of the soil in the pot all over, and not from the rose of a watering-pot, however fine. Even when seedlings are up this sailing with water, in the case of small seedlings, is of importance. The simplest plan to adopt is to have an oyster shell, or a rounded piece of broken pot, hold it obliquely with the left hand against the inner rim of the pot, and pour the water from the spout of a small watering-pot upon the crock until the water floods the pot without touching the top of the seedlings. Water such tender little seedlings overhead with a fine rose, and if they are at all close together there will be a great risk of their damping or fogging off at the collars. Several have asked how there could be such a difference? and we were obliged to own here our comparative ignorance. It is one thing to note a fact, and quite another thing to be able to tell all the reasons why. It is a fact that diffsrent results will follow from different modes of watering tender seedlings. When glass, as stated above, is not handy, a saucer will answer the same purpose. Many seeds require this protection before they are up as a security from vermin. The advantage of the glass square is that you can regulate light to a nicety.

We meant to have said something about cuttings, but would now merely remark that the chief point is to keep the cutting growing, so as to suffer as little as possible from its severance from the parent plant.—R. F.

TRADE CATALOGUES RECEIVED.

Edmondson Brothers, 10, Dame Street, Dublin.—*Spring Catalogue of Vegetable and Flower Seeds, Garden Implements, &c.*

George White, 3, Moss Street, Paisley.—*Select List of Pansies, Pinks, &c.*

"*Portable Plant Protectors, and How to use them.*"—"*Vines and Ground Vineries.*" By W. Edgcumbe Rendle. London: Simpkin, Marshall, & Co.

W. Clibran & Son, Millbank Nursery, Warrington.—*Descriptive Catalogue of New and Choice Plants.*

S. Shepperson, Prospect House, Belper.—*Catalogue of Pansies, &c.*

B. J. Edwards, 222, Strand, and 25, Bishopsgate Street Within, London.—*Spring Catalogue of Flower and Vegetable Seeds, New Hybrid Gladioli, &c.*

TO CORRESPONDENTS.

*** We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By doing so they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

N.B.—Many questions must remain unanswered until next week.

Books (*Rosa*).—There is no recent work on Melon culture exclusively. The fullest and best directions are in our Nos. 197, 199, 201, and 283, which you can have from our office if you enclose 1*s.* 2*d.* in postage stamps with your address. (*A Young Gardener*).—"Repton's Landscape Gardening" by Loudon. We do not know the publishers of the other work you name.

White Azaleas (*Julia*).—Louise Von Baden, Louise Margottin, Flag of Truce, and Iveryana.

Mowing Machine (*S. F. D.*).—Any would answer your purpose. You may see specimens at Mr. J. C. Fex's, Horticultural Agent, Arcade, Royal Horticultural Society's Garden, South Kensington.

Barkeria spectabilis Culture (*D. M.*).—Barkerias being plants which make thick fleshy roots, and which enjoy a cool temperature, are easily injured if the roots are confined amongst moss or other wet material. They nevertheless enjoy a copious supply of water during the season of growth, and we have always found them thrive by far the best when fastened upon blocks of wood, with but very little moss; the roots will readily adhere to the wood and remain firmly fixed. They may, however, be grown in pots if preferred, in which case the pots should be quite filled with moderate-sized pieces of charcoal and potsherds, which for appearance may be slightly covered with living sphagnum. If the roots of your plant show the least sign of decay, remove it to a block of wood or piece of cork before it starts into growth, this method being undoubtedly the best to ensure the well-being of all the species belonging to this beautiful genus.

Grass Seeds for a Lawn (*T. H. T.*).—For your lawn of a quarter of an acre which requires renovating, we should sow Trifolium minus only, and 3 lbs. would do it well; this Clover, as you say, stands dry weather well—indeed, with us better than anything else, and gives a close bottom sooner than grass seeds. Do not sow before April, and then during the first moist weather, rolling well after sowing.

Eucalyptus globulus Leaves Warted (*A. Z.*).—The small warts or excrescences on the under side of the foliage are very common on the mature leaves, but we think the leaves have been infested with red spider, which may be destroyed by syringing or sponging them with a solution of 2 ozs. of soft soap to the gallon of water, applied at a temperature of 140°, or if you sponge the leaves, which is better, use it at 120°.

Wiring a Vinery (*Croydonian*).—The best plan is to have the wires crossing the rafters, or lengthwise of the house, and 9 inches apart. You will need an angle iron at each end secured to the end timbers, and a piece of ordinary bar-iron, five-eighths of an inch by a quarter of an inch, at every rafter, or 3 to 4 feet, and these will need to be supported by hangers or holders screwed into the rafters, and secured top and bottom by screws to the uprights or rafters. The angle plates and the smaller iron supports will need to have holes drilled 9 inches apart, through which the wires are to be drawn. Each end of the wires should be prepared to receive a thumb-screw, by means of which the wires can be tightened. No. 10 wire is commonly used, but we employ No. 6. Any of the firms advertising in our columns could supply you. We cannot name one in preference to another. The wires should be fixed 14 to 16 inches from the glass.

Deutzia Treatment (*Idem*).—We can only account for your plant being in such a poor plight from the high temperature in which it is kept, and from its being in a bad state before forcing was commenced. Place it in a house with a temperature of from 45° to 50°, keep it supplied with water, and afford it a light airy position. After flowering, or in April or May, remove it to a cold pit or cool airy house, and in May place it out of doors in an open situation. Keep it duly watered in summer, and before severe weather sets in place it in a sheltered position, the pots plunged in ashes. About Christmas turn the plant out of the pot, remove any old loose soil, and pot again in a pot large enough to hold the roots. Introduce it into a house with a temperature of from 45° to 50°, and the plant will flower in six or eight weeks. This is all we do to our plants, and we have had them in flower from the beginning of January, they being placed in heat at the end of November. Light turfy loam with a little leaf soil and sand grow them well.

Planting Out Calceolarias (*A Constant Subscriber*).—The beginning of April is sufficiently early to transplant them into beds from under the hand-glass, and even then they will require protection at night and in frosty days. If you can afford them protection from frost, you may transplant them any time after this in mild weather.

Short Stems of Hyacinths and Tulips (*Idem*).—The shortness of the spike of the Hyacinth may be owing to the bulb, but the spike may have plenty of flowers and yet be short, from the plants not having had sufficient heat for their full development. The watering and soil would

not cause a short spike, though any deficiency in either respect would cause it to be poor. Tulips potted in September would flower at Christmas, if they had a temperature of from 50° to 55° a month or six weeks previously, and were early-flowering sorts. They would flower now with a temperature averaging 45°.

CASES FOR OUR VOLUMES (*Maida Hill*).—We only supply the cases.

PLANTING-OUT TACSONIA MOLLISSIMA (*Amateur, Dublin*).—The plant turned out last November in a conservatory border ought to be now in a state of growth. It is not usual for it to die down in winter. We have one in a greenhouse, and it is now very vigorous and growing freely, having made shoots several feet long since Christmas, and it is showing bloom at every joint. We only planted it last May, and it flowered and fruited in the past season. We should say your plant is dead.

DISSOLVING BONES (*Idem*).—You will require a weight of sulphuric acid equal to one-half that of the bones. The finer the bones are, the sooner will they dissolve. Dissolved bones are applied to the soil mixed with soil or ashes, and mixed with water as a liquid manure. You will need to dilute with fifty times as much water as the acid employed, calculating by weight, a gallon of water weighing 10 lbs. 8 bushels of dissolved bones, irrespective of the acid, are a good dressing per acre.

LEAVES FOR LEAF MOULD (*Idem*).—The time required for leaves to decay depends on whether they are kept dry and left undisturbed. If laid in a heap and turned over twice or thrice they will be reduced in twelve months. We use our leaves for hotbeds, and by autumn again they are sufficiently decayed for potting purposes. If undisturbed we have known two and three years elapse before the leaves were fit for mixing with soil. We sift ours through an inch-riddle, and when the majority pass that, the leaves are, in our opinion, sufficiently decayed.

CAMELLIAS NOT FLOWERING (*A Subscriber*).—We cannot account for your plants not flowering, as they set buds but fail, only we think the roots are in a bad state. We would, at the end of March, turn them out of the pots, pick away any old soil that you can without injuring the roots, and repot in a compost of the top inch, or not more than 1½ inch, of a pasture where the soil is a good light loam. Chop it up small though not very fine, and pot with this, without admixture, rather firmly, taking care to leave no hollows. Place the plants in a house with a temperature of 50°, watering so as to keep the soil moist, and when they are growing water abundantly. Maintain a moist genial atmosphere, and afford slight shade from the bright midday sun. Keep the plants there until the growth is complete and the buds are set, then remove them to a cool airy house; and if you afford, from November to April, a temperature of 40° to 45° from fire heat, we think you will have a fine bloom. Drain the pots well. Do not place the plants out of doors in summer.

IVY PRUNING (*C. A. S.*).—In pruning Ivy against a wall we cut clean-in, removing every leaf, but we do not think it safe to do this until April, which we consider the best month for cutting Ivy. It makes a much closer growth when cut-in with the shears than when pruned with a knife, some green leaves being left.

LEAVES BLIGHTED (*S. H.*).—The leaves of the plant you describe as a Daisy, but which we do not recognise, are infested with thrips, which may be destroyed by fumigation with tobacco, or immersing the plants in a decoction of tobacco. This is made by pouring a quart of boiling water over 1 oz. of tobacco, afterwards covering it up and letting it stand until cool. Of course, you must not dip the pot and roots. Out of doors the plant will show the effects of thrips, but can hardly suffer from it except in very dry weather.

SHRUBS FOR A MOUND (*Wm. D., jun.*).—The outer margin or foot we should plant with Berberis Aquifolium, and then common Laurel, with a few Portugal Laurels, Lilacs, Laburnums, Syringas, and double Thorns, interspersed at, say, 15 feet apart, and the crown we would have Austrian Pine. These are not expensive. The Berberis may be planted 4 feet, and the others 6 feet apart.

VINES TENDRILLED BUT FRUITLESS (*Old Subscriber*).—We have no doubt that the reason why your vigorous Vines in pots show tendrils instead of bunches, is owing to the Vine wood being imperfectly ripened, very likely from growing in shade, instead of full exposure to light. We consider it would be anything but safe to cut the Vines back now, with any hopes of their making fresh wood and yielding fruit this season. We saw this done once with established Vines that lost their first crop though an accident, but it did no good as respects fruit, and nearly ruined the Vines. There are two modes of treating your strong Vines —If not too far advanced, you might prune them back to a good shoot near the base, and grow that as a single cane in summer to fruit next year; or you may stop your present side shoots—say at 18 inches long, and have them well ripened before the autumn. We are sorry that you have failed after so long a preparation, and especially as you say the wood was well ripened. We have our doubts as to the maturity. Did you pot the Vines in autumn or before forcing? They should have no fresh potting after July or August, so that the pots should be full of roots. The treatment is correct, only we would not let Vines have 70° during the day until the first month were past. In sunless weather 60° by day would be enough, and 50° to 55° at night, beginning with from 45° to 50°. We like the rods to be twisted round, though if care be taken in the breaking, the plants should do very well fastened to a rod 5 feet long.

PROPAGATING VINES (*Idem*) —It matters little how the plants are raised. We prefer using single eyes with an inch or so of wood on each side. Eyes inserted in December and January, and receiving all the time bottom-bed treatment, may be got by repeated shiftings into 12, 15, or 18-inch pots by midsummer, then ripened, exposed in autumn in the shade, and started in November or December to fruit early; but there must be close unremitting attention. Another mode is to put in cuttings or buds in spring, and get the plants established in 6-inch pots in summer, rest in winter, and cut down, grow, repot, and ripen early the second summer, giving two summers' preparation instead of one. This mode takes more time, but less labour and attention.

CLIMBERS FOR A CONSERVATORY (*E. C. K.*).—For growing in pots we have found the following answer:—Brachyæma acuminata, Cobæa scandens variegata, Dolichos lignosus, Habrothamnus elegans, Hibbertia volubilis, Jasminum grandiflorum, Kennedya variegata, K. inophylla floribunda, K. Marryattæ; Lapageria rosea, Passiflora Comte Nesselrode, P. Impératrice Eugénie; Rhynchospermum jasminoides, and Sollya linearis. The size of pots depends on the plants; they need shifting from one size to the other until they are in their full size, which, for the first season need not exceed 9 inches in diameter, and the next 11 inches; and a 13-inch pot we consider quite large enough for the third and subsequent seasons, the ball being reduced at the annual spring potting.

GLAZING GREENHOUSE ROOF (*J. Smith*).—A rough plate or fluted glass roof will do admirably for a greenhouse, and requires no shading in summer, and gives plenty of light in winter; but we prefer the front lights to be of clear sheet glass, so as to see through them.

ASPECT FOR GLASS STRUCTURES (*W. H. F.*).—The 10 yards freely exposed to east, west, and north, are excellent for glass houses, either for fruit or flowers. For the other 10 yards, more or less blocked-in to a height of 25 feet, we would advise covering with a glass roof, and devoting that space to Ferns and fine-foliaged plants. The plants indicated would do well, but if you prefer fruit and flowering plants, we do not think you would succeed in the shaded part. Plants would keep longer in bloom there, but would not grow and come into bloom so well.

DISBUDDING VINES (*M.*).—We are a little in doubt whether you refer to Vines in pots, or to Vines growing in the usual way; but in either case when you secure as many fruit-bearing shoots as you wish, and a few others, as may be wanted for future wood, it is well to rub off the extra shoots. On the rod system, leave another for rods; on the spur system, leave enough, though not fruitful, for future spurs where wanted. Fruitful Vines require a great deal of rubbing off.

FLOWER GARDEN PLAN (*An Earnest Reader*).—For the scroll beds we prefer Christine Pelargonium for the centres, and the other beds as proposed, dotted with Bijou. Both of the proposed modes would look well, but we think Bijou and Iresine Lindeni would contrast better. We also like very much the proposed arrangement for the border, only we would hint that you may have the Perilla of any height, but cannot so well top the Ageratum; and as the Berberis, &c., behind will do little more than make a background, we should be inclined to place the Perilla behind the Calceolaria, and the Ageratum behind Stella Pelargonium.

CUCUMBER-HOUSE FAILURES (*An Old Subscriber, Richmond*).—A bed 3½ feet wide, with a depth of 18 inches, is quite room enough for the roots of Cucumbers that you grow in the front of your house. It is quite possible to have too much bottom heat, but it is just as possible that the evils you complain of are the consequence of the heat being too dry, and hence the baked appearance of the soil next to the slate, &c. Now, supposing you had a chamber covered with slate, and covered the slate with 2 or 3 inches of rough rubble, and had upright drain-pipes standing in that rubble before you put in the soil, by pouring water down the drain-pipes, and having a stick in several, with a ball of moss fixed at the end, you could always judge of the dryness or moisture of the rubble. We have nothing to say against chambers, but the roots should never come in contact with the dry covering. Where pipes are used for bottom heat, there is no simpler and better mode than that frequently recommended by Mr. Fish—namely, to surround the pipes with open rubble, cover slightly with the same, and then make the bottom of the bed with clean gravel, and by upright pipes, as above, have the means of damping the rubble and gravel, and yet not do so too much.

PRUNING YEW TREES (*An Old Subscriber*).—The beginning of April is the best time to do this, and you may prune to any extent without fear of the tree not putting out shoots from the thick bare stems. The fresh shoots made this year we would not cut, but in the April of the following year we would cut off any irregularities of growth, and in subsequent years clip in May, and the tree will grow sufficiently to give a nice feathery appearance—very much grander than that close stiff formality resulting from cutting in August when the growth is complete. It is well, however, to go over the tree in August, and with a knife remove any irregular growths.

SOILS (*A Subscriber*).—1, "Strong turfy loam" is the top 2 or 3 inches of pasture where the soil, from the absence of sand or gravel, is close, and overlies a clay subsoil. 2, "Hazel loam" is a medium-textured loam, not light-sandy nor yet heavy-clayey, and of a hazel colour—brown streaks through yellow. 3, "Sound deep light loam," we presume, is a soil not very light, yet more sandy than a clayey loam, but more retentive of moisture than sandy soil, and of some depth. 4, Alluvial soil is that of freshwater deposits, forming in the course of ages the rich soil of valleys. 5, Peat is vegetable matter reduced to soil, and is found on moors, and is covered with Heath or Ling. That on high ground is peat, as used by gardeners, and is full of fine particles of white sand.

VARIEGATED BEDDING PELARGONIUMS (*Maria Henderson*).—We presume you mean Gold and Silver Tricolors only. Then, as you exclude new kinds, of the former Mrs. Pollock, Sophia Cusack, Lucy Grieve, Sophia Dumaresque; of the latter, Mabel Morris, Italia Unita, Prince Silverwings, and Glen Eyre Beauty.

TURNIP SOWING (*A Beginner*).—Your proposed plan ought to produce a good crop, if the Turnip fly allow you to have a good plant.

MUSHROOM BED (*A. D.*).—As the beds are to be on the floor, we would have a walk of 2 feet or 30 inches down the centre, and beds 9 feet long and rather more than 4 feet in width. Our shallowest beds we would have about 12 inches deep in front, and from 15 to 18 inches deep at back. For winter work we would have them a little deeper, and depend on surface-covering to keep up the necessary heat. Now, there are many ways of making such beds. Collect the horse droppings with nearly an equal portion of short litter for a week or ten days, and lay them in any place, not too thickly, where no rain will fall on them. Then add a barrowload or two of dry soil, mix all together, and make this the base of the 9-feet bed. Beat it firmly together, and it will heat very moderately. Then every second day add the droppings, and the same amount of short, dryish litter all over, tread or beat, and then put a little dry soil over. Continue the process until the necessary height is secured, as referred to above, for the different seasons. By this plan as will be perceived, the bed will never become very hot, and the bulk of the manure will be fresh—full of nitrogenous matter—and, therefore, capable of carrying a heavy crop of Mushrooms.

HEADING MAIDEN PEACH TREES (*Probo*).—The trees should be headed down early in March to within five eyes from their base; or, if the buds are wide apart, cut back to an eye not more than 6 inches from the junction of the shoot with the stock. You will secure five shoots—two for each side, and one for a leader. Erébaut's "Modern Peach-Pruner" is the best work of the kind. It may be had by post from our office if you enclose 3*s.* 8*d.* in postage stamps with your address.

PLANTING GLADIOLUS SPAWN (*Amateur*).—Plant about the middle of March if the ground is in good working order, having had it previously well turned up to a depth of not less than 15 inches. If the soil is clay, or otherwise unsuitable, it should be removed to the depth of 18 inches, and if the subsoil is wet, take out a further depth of a foot; then fill up with any kind of rough material, as stones, brickbats, &c., and cover the drainage with stable litter, throwing in good soil enriched with leaf soil and well-decomposed manure. If the soil is wholly bad, prepare an artificial compost of two parts turfy loam—all the better if the soil inclines to a sandy peat—one part sandy peat, and one part well-rotted manure. Chop the turf up pretty fine, mixing all well together, put in 18 inches deep of this compost, and cover the bed with 6 inches of soil. The bed should be raised 9 inches above the surrounding level. Prepare them at once, and in a fortnight it will be advisable to plant. Divide the offsets into two sizes, the large and small; plant the former in rows 6 inches apart, and 4 inches apart in the rows. Draw the drills 3 inches deep, and cover the bottom with sand, put in the offsets firmly, covering each with sand, and draw the soil over them. The smaller offsets may be planted in the same way, but much more closely together. Water freely in dry weather, and overhead in the evenings of hot days.

BEDDING CALCEOLARIAS (*Idem*).—It is not advisable to place those that have been wintered in a cold frame in a hotbed at this or any season. If they are too close together thin out every alternate plant and row, and replant in a cold frame.

CLIMBERS FOR A PORCH (*J. S. S.*).—No plants will produce such a good show of flowers on an east aspect as Roses, and we advise Russelliana (Multiflora) and Dundee Rambler (Ayrshire). These will be sufficient, one being planted on each side.

EDGING FOR KITCHEN GARDEN WALKS (*R. S.*).—We do not think the Saxifrage would suit, nor yet Thrift. London Pride (Saxifraga umbrosa) would no doubt answer, but we should prefer next to Box the Bush Alpine Strawberry. Ivy does well, but is very troublesome to keep in order; the most suitable for edgings is Hedera Helix poetica, or common Wood Ivy. H. taurica is also good. The Fern so full of ripe spore-cases is Lastrea glabella, and the pale green spare-looking kind is Asplenium flaccidum.

CLOUDING GLASS (*T. U. U.*)—You may "muffle" the glass of your fernery by dotting the inside with thick whitening well sized. Apply it by the end of a large painter's brush.

PLANTING POTATOES (*C. C.*)—Such large varieties should be planted 9 inches below the surface. Use decayed dung; if you put it into the trench let it be below the sets. See what is said to-day about the Bovinia.

PLANTING PATERSON'S BOVINIA POTATO (*C. P.*).—If your ground is very good loamy soil allow quite 42 inches between the rows, and 18 inches set from set. But if you decide upon alternately planting with a first-early sort, to dig out of the way of the Bovinias before the latter "become very large in the top," then 30 inches would not be too much to allow between the rows. Hogg's Early Coldsteam (round) and Myatt's Early Prolific Kidney are to be preferred for quite early use, and I have often thus planted alternately late coarse-foliaged and first early kinds on my ridge-and-trench system, sowing a pinch of early white Turnips daily on the site from whence I dug the young Potatoes, with very good results. If the late Mr. Paterson had taken me as a "friend in council," I should have advised him at this time of day not to have introduced his Bovinia to the public. By so doing he retrograded to Ox Noble, Farmer's Glory, Mangold Wurzel Potato, and the Stoker and Nigger set, the like of which, as some of my own recent seedlings, I have just relegated to the copper in order to make quite sure that they will not be handed down to posterity; because in 1841 I was taught a valuable lesson by the pigs, by giving them Farmer's Glory and Birmingham Blues for breakfast. They fought over the trough containing the "Brummagems," and turned up their noses at the former till not one of the latter remained. That proved a death blow to the Glory and all its class in my opinion. If you boil some Paterson's Bovinia and Victorias, and fill two troughs of each respectively for the pigs to choose from, they would for preference consume the Victoria first; and as the Victoria is a much larger yielder than the old Birmingham Blue, and withal nearly as good in quality, let me advise you to cultivate it in preference to the Bovinia, on the understanding that the Victoria would not yield so large a bulk as the latter, although having a greater amount of fattening properties.—ROBERT FENN.

NAME OF FRUIT (*C. C.*).—Early Nonpareil.

NAMES OF PLANTS (*Grogee Bysails*).—1, Pteris asperlcaulis, var. tricolor; 2, Adiantum formosum; 3, Cheilanthes myriophylla; 4, Polystichum angulatum. (*T. B. W.*).—1, Cheilanthes Sieberi; 2, Doodia caudata; 3, Polystichum aculeatum; 4, Asplenium lucidum; 5, A. flaccidum. (*Penzance*).—3, Grevillea rosmarinifolia. The two others were not in bloom, and were not identified by us from the leaves.

POULTRY, BEE, AND PIGEON CHRONICLE.

OUTRAGES ON PRIZE POULTRY—HOW SHOULD FOWLS BE HANDLED?

THE accounts given by Mr. Cresswell and Mr. Will as to how their poultry have suffered ought to secure the attention of all interested in poultry matters, with the view of endeavouring to find out the perpetrators of the outrages, if such there be. I can hardly fancy that a person fond of poultry, or who has any taste for the fancy, could be so base as to disfigure a bird on his chance of winning. Now, I must candidly say that I believe the blame lies with the committees of poultry shows in not selecting proper persons to unpack and pen the birds. I am now becoming an old exhibitor, and, of course, have been at many shows, and I frequently found the committees had engaged to unpack poultry a man or men who had no idea how to handle a bird—no, not more than a tom cat.

Not many months ago I saw the clearance of a poultry show after the show was closed, and I noted how the birds were taken out of the pens. As soon as the packing began, the cry and cackle were general all through the show. All the birds seemed alarmed. Four men seemed to have undertaken the job with the assistance of several exhibitors. The hampers were drawn out from under the pens all in hurry-scurry. "Now, Jack, look sharp!" and Jack did look sharp, for no sooner was the pen open than Jack made a grasp at a Game cock—tail and leg together—of course, feathers had to come with the bird, but not all of them, for there was a handful left in the pen. The Hamburghs fared no better from their disposition to fly about; but one old Duck seemed not to be taken out in such an unprofessional manner. She was taken by the leg, but she would persist in spreading out her wings; so that was no way to bring her out. The next grab was to take hold of the wing, and by that means she was dragged out, and tumbled into the hamper. This is no common occurrence.

I consider that no subject connected with poultry requires more attention and discussion than the way in which different kinds of poultry should be handled—that is, some of our judges or exhibitors might state in the Journal how to take birds out of a hamper and place them in the pens, for there seems to be some art in managing this properly. Just observe how quietly our judges handle a Game cock. How do they take him out of a pen, and without disturbing a feather?

A few hints from exhibitors will not be out of place, and I fancy the managers of poultry shows would like information.

In conclusion, I just put the question, Which is the best way to take out of a pen the Goose, Turkey, and Duck, &c.? Should the legs, wings, or head be the place to take hold of?—R. D.

JUDGES CLAIMING BIRDS AT POULTRY SHOWS.

PERMIT me, through your Journal, to call the attention of poultry exhibitors to the unfairness of permitting the Judges to claim birds before the shows are opened to the public.

Hearing there would be a good collection of birds at Wolverhampton Exhibition on the 3rd inst., I went there to see if there were any pens I should like; and knowing, from previous experience, the necessity of intending purchasers getting in as early as possible, I was on the spot before the doors were opened, and was the second person in the hall. My attention was taken by a pair of Dark Brahma hens, and I hastened to the Secretary's office to purchase them. It was not then open, but I waited till he came, and was told the birds were sold, much to my astonishment, as I had been the first to claim them legitimately. Asking the purchaser's name, that I might treat with him, I was informed he was one of the Judges, and that he had claimed them before the opening of the show. I think this is anything but fair to the public, and trust you will insert this letter, that poultry fanciers may endeavour to prevent the repetition of such an injustice.—JAMES WATTS, *Hazlewell Hall.*

EXHIBITING CARRIER PIGEONS.

I QUITE concur in the remarks of Colonel Hassard in page 112, that the exhibiting of Carriers in pairs is disadvantageous alike to the promoters of shows and to exhibitors. At any period of the year save the winter months few breeders would be induced, even for the honour of prize-winning, to break their pairs as mated together, which in all probability would be done so that they would be no match in colour or other properties for successful competition.

I have been requested to show at the forthcoming Colchester Exhibition where the birds are to be shown in pairs, but having commenced pairing for this year's breeding I am compelled to decline doing so. Had the birds been shown singly I should have entered, as, out of a lot, some one or two might have been sent that at the time had not commenced to breed, but to part pairs and remate for showing is quite out of the question.

Carrier classes are generally well filled, and frequently self-supporting from the amount received in entry fees, and at all shows that rank of any importance there should be four classes—viz., Black cocks and hens separately, and the same with Duns or any colour; and why not represent the Blues, which I fear from lack of encouragement have not progressed of late years as the others?

May I take this opportunity of informing Carrier fanciers that our schedule of the Spalding Show for next June's competition

comprises five classes in single birds, instead of two only as heretofore? Though the Committee are aware the height of summer is not a time to expect the fullest entry, they anticipate no loss by the increase of the classes. I hope Colonel Hassard will put in an appearance here.—WILLIAM MASSEY, *Spalding*.

TORQUAY POULTRY SHOW.

IT must be a source of gratification to a remarkably attentive Committee to have found so excellent a collection of birds as that brought together at this Show, held from the 15th to the 17th inst., as well as an attendance of visitors that has rarely been equalled at any poultry show in the west of England. Mr. Beachey, of Finder House, Kingskerswell, has proved himself an able secretary, and the present high position of the Torquay Show is attributable in no small degree to his indefatigable efforts. Messrs. Turners' exhibition pens were a decided improvement on the arrangements of last year, and the expression of satisfaction among the visitors was general.

The display of Grey *Dorkings* was excellent, and it is very rarely these classes are throughout so well filled. The White Dorkings were also remarkably good. Of the *Cochins* the White were certainly the best shown, the majority of the Buffs being evidently suffering from over-exhibition. At the show of last year the Dark *Brahmas* were the first feature of the exhibition, but this year the entry was not of nearly equal quality. A very large number of Light Brahmas were entered, a few of which were very superior, but the bulk were quite overshown. Mr. Paree, of Guildford, won the silver cup with his well-known pen. *Spanish* were good throughout, but the rigour of the last few months had told most severely on the combs of many of these birds. Never was there a better display of *French* Fowls seen at any previous English show, and the really faultless condition, and excellent health in which they were shown, proved they were perfectly acclimatised. *Ducks* were all good classes, the Variety class especially so. The prizes were awarded as follows:—Viduat Whistlers first prize, Buenos Ayrean second, a grand pen of Carolinas third, and Mandarins fourth prize. The Selling classes were very large, and as most of these entries were worth far more than the restricted price, as stated in the catalogue, a very large sale was effected.

The *Pigeons* were not so numerous as was anticipated, but this could be easily accounted for by the fact of several shows being held simultaneously. So good, however, were some classes, that every pen was favourably noticed by the Judge. The rivalry to secure the silver cup offered to the best exhibitor of Pigeons was very keen, and excited much public interest, the two principal aspirants being Mr. Taylor and Mr. Yardley, the latter, though successful, being so very closely run as to win only by a single point.

DORKINGS.—*Coloured, except Silver-Grey.*—1, 3, and Cup for best pen of poultry shown by residents in Devon, Somerset, or Cornwall, L. Patton (Grey). 2, J. Martin. 4, Mrs. Wollocombe. *hc*, G. Whitcombe; H. Pickles, jun. *c*, R. W. Beachey. *Silver-Grey and White.*—1, Mrs. E. Williams (White). 2, R. H. J. Gurney. 3, W. E. George.

COCHINS.—*Cinnamon and Buff.*—1, Miss J. Milward. 2, W. F. Checkley. 3, S. R. Harris. 4, J. Watts. *c*, Mrs. Wollocombe; W. Masland. *Any other Variety.*—1, J. Sichel. 2, S. A. Wyllie. 3, C. F. Wilson (Partridge). 4, F. Wilton (Black). *hc*, W. E. George (White); J. H. Dawes. *c*, J. K. Fowler.

BRAHMAS.—*Dark.*—1, J. H. Dawes. 2, J. Dove. 3, Rev. J. Bowen. 4, J. Sichel. *Light.*—1 and Cup for best pen of Light Brahmas, J. Pares. 2 and 3, A. O. Worthington. 4, T. A. Dean. 5, J. R. Rodbard. *hc*, C. W. Croft. *c*, F. Crook.

SPANISH.—1, H. Beldon. 2,—Allsopp. 3, H. Lane. 4, J. Watts. *c*, E. Jones; Howard & Nichols.

FRENCH FOWLS (Houdans, La Flèche, and Crêve-Cœur).—1, J. Sichel. 2, F. Brewer. 3, W. Burrows. 4, H. Beldon. *hc*, C. H. Smith; Rev. N. J. Ridley; W. Dring. *c*, Major Irving (3); Rev N. J. Ridley.

HAMBURGHS.—*Gold and Silver-spangled.*—1, H. Beldon. 2, H. Pickles, jun. 3, Ashton & Booth. 4, Lady Vivian. *hc*, H. Pickles, jun.; Miss E. Browne; J. Ogden; N. Barter. *c*, H. Beldon; H. Pickles, jun. *Gold and Silver-pencilled.*—1 and *hc*, H. Pickles, jun. 2, N. Barter. 3, H. Beldon. 4, Rev. A. T. Willett. POLISH (Any variety).—1, D. Mutton. 2 and 3, H. Beldon. 4, T. Dean. *hc*, W. Boyes; H. Pickles, jun.; M. Nicholls; D. Mutton; W. Gamon. *c*, A. Cruttenden; W. Boyes.

GAME.—*Black and other Reds.*—1, 4, and *hc*, W. Boyes. 2, S. R. Higham. 3, S. Matthew. *c*, W. H. Stagg; J. T. Browne; R. Stork; E. Bell. *Any other Variety.*—1 and *hc*, S. Matthew (Duckwing). 2, J. T. Browne (Duckwing). 3 and 4, W. Boyes (Duckwing).

BANTAMS.—*Game.*—1, E. Cambridge. 2, R. Swift. 3 and 4, Withheld. *Any other Variety.*—1, E. Cambridge (Black). 2, H. Beldon. 3, S. & R. Ashton. 4, M. Leno (Laced). *hc*, R. Coath (Black); H. Yardley. *c*, W. Boyes (2).

DUCKS.—*Rouen.*—1 and 4, L. Patton. 2, J. K. Fowler. 3, S. R. Higham. *c*, Mrs. M. Seamone. *Aylesbury.*—1 and 3, Mrs. M. Seamons. 2, J. K. Fowler. 4, T. F. Hawken. *Any other Variety.*—1 and 4, M. Leno (Viduata Whistling and Mandarin Ducks). 2, W. E. George. 3, Rev. W. Sergeantson. *hc*, W. Boyes (Black East Indian) (4); G. S. Sainsbury (Black East Indian); J. K. Fowler. *c*, Mrs. M. A. Hayne (Black East Indian).

ANY OTHER VARIETY.—Rev. W. Sergeantson. 2, W. Wildey (Andalusian). 3, W. Boyes (Sultans). 4, H. Beldon. *hc*, Hon. J. Masse (Malay); Mrs Llewellyn (Sultans); W. Wildey (Andalusian). *c*, J. Hinton (Malay); Rev. N. J. Ridley (Leghorn).

SELLING CLASS.—*Cocks.*—1, H. Lloyd, jun. (Cochin). 2, Miss E. Browne (Spanish). 3, R. W. Beachey (Brahma). 4, J. H. Nicholls (Cochin). *hc*, H. Beldon; H. Pickles, jun. (Poland); A. C. Travers (Game); R. Pile (Brahma); H. Yardley; J. Dove (Cochin); R. Wright (Spanish). *c*, W. Yelland (Crève-Cœur); J. N. Whitehead (Cochin); J. Long; F. Brewer (Houdan); Howard and Nichols. *Hens.*—1, J. H. Nicholls (Cochins). 2, Howard & Nichols. 3, Miss F. Brown (Spanish). 4, J. N. Whitehead (Cochin). *hc*, J. Easterbrook (Black Minorca); Mrs. M. Seamons (Dorking); H. Pickles, jun. (Polands); H. Lane (Spanish). *c*, H. Beldon; R. Stork (Game); S. A. Wyllie (Polands); R. Pile (Brahmas); R. W. Beachey (Brahmas and Dorking) (3); F. Brewer (Dorking).

Cup for the most successful exhibitor in the poultry classes.—Mr. Beldon.

PIGEONS.

CARRIERS.—1, H. Yardley. 2, E. Horner. *hc*, G. J. Taylor (2). *c*, E. Horner; H. Yardley.

POUTERS.—1, G. J. Taylor. 2, E. Horner. *hc*, E. T. Dew. *c*, E. Horner.

TUMBLERS.—1, G. J. Taylor. 2, E. T. Dew. *hc*, G. J. Taylor; E. Horner. *c*, C. Bulpin.

BARBS.—1, G. J. Taylor. 2, H. Yardley. *hc*, E. Horner.

JACOBINS.—1, G. J. Taylor. 2 and *c*, E. Horner. *hc*, J. & C. Bullen; C. Bulpin.

FANTAILS.—1, H. Yardley. 2, W. H. Tomlinson. *hc*, J. F. Loveridge. *c*, E. Horner; W. H. Tomlinson.

TRUMPETERS.—1, E. Horner. 2, P. H. Jones. *hc*, W. Masland. *c*, W. Mudge C. Bulpin.

OWLS.—1 and 2, P. H. Jones. *hc*, J. Ford.

NUNS.—1, H. Yardley. 2, T. A. Dean. *hc*, T. A. Dean; F. Graham.

DRAGOONS.—1 and 2, G. South.

ANTWERPS.—1 and 2, H. R. Wright. *hc*, W. H. Mitchell; H. Yardley.

TURBITS.—1, H. Yardley. 2, P. H. Jones. *hc*, G. J. Taylor; G. H. Gregory; E. Horner.

ANY OTHER VARIETY.—1, C. Bulpin (Archangels). 2, J. Bowes. *hc*, C. Bulpin (Helmets); J. Watts; E. Horner.

Cup for the most successful exhibitor in the Pigeon classes.—Mr. Yardley.

The Judges of poultry were the Rev. G. F. Hodson, and Mr. Edward Hewitt; Mr. Esquilant officiating for Pigeons.

FARM BREEDING AND MANAGEMENT OF POULTRY.

AT a meeting of the Midland Farmers' Club, held February 8th, the following remarks were made on this subject:—

The Rev. A. G. BROOKE (of Shrawardine, Salop) said:—Mr Chairman and Gentlemen, the subject for our consideration to-day, "The Breeding and Management of Poultry," is, you will admit, one of great importance, and the few remarks which I am about to make will, I trust, lead to an interesting and profitable discussion. First, then, as regards "the breeding of poultry." When we find from statistics that an immense quantity of poultry of all descriptions is annually imported into this country from France and Germany; that hundreds of millions of eggs are imported yearly, and that in spite of that terrible war which has been so long raging, 22,000,000 of eggs arrived from France during November in last year, it must surely be admitted that for some time past we have too much neglected our farmyard poultry, which forms in these days such an important market commodity as food for the people. Take the generality of poultry in farmyards, and what do you find? A quantity of fowls of all sorts and sizes, mostly the result of breeding in-and-in for years past, the owner continually grumbling because they cost so much to keep, the feeding being generally left to a personage known as the boy, who feeds the fowls and hunts up the eggs, and most liberally throws down handful after handful of grain with more zeal than discretion, and then, in the winter months, when eggs are scarce and might be a great source of profit, few, if any, are to be found. It is all very well, you may say, to point out defects, but where is the remedy? Simply in this, that the majority of farmers need, with their poultry, reform. To make poultry profitable, you must first of all start with the breed that will ensure you success.

Having been a most successful exhibitor and breeder for nearly twenty years, and having kept almost every variety of the feathered tribe and tested their merits, permit me to recommend to you the following suggestions:—Either send to market and so dispose of every fowl in your yards (and you will never have a better time of year for getting rid of them than the present), and then commence with an entirely fresh strain; or else keep about a dozen of the best and biggest of your pullets, and purchase another bold chanticleer to proclaim the morn, and thus introduce fresh blood amongst them. As regards starting with an entirely fresh strain (the doing which I most strongly recommend), you will find that it will answer your purpose best to keep Dark Brahmas—say a two-year-old cock and six pullets, by way of a start, and for this reason. They are very hardy, extremely prolific, and good mothers; if hatched in April, they will lay during the winter months, and, with a liberal supply of good food, the chickens attain size and flesh very fast; can soon be got ready for the market, and are by no means coarse for the table. In addition to this, they are handsome, and an ornament to the farmyard; the eye is naturally pleased by seeing a true and pure strain of fowls foraging about, and in these days of poultry exhibitions, good birds (especially of this breed) command high prices, and you will find them very remunerative. As an instance of this, I commenced keeping Brahmas some four years ago (having heard them so highly spoken of), and purchased some prize birds. The first time I exhibited this breed was at Middleton, near Manchester, and with a cockerel seven months old I won the first prize, and the bird was claimed at the catalogue price, £5. Since then I have occasionally bought eggs, in the spring, from exhibitors on whom I could depend, and have been most fortunate in hatching early birds. Most of them I sold at the rate of 50*s.* the cockerel and two pullets; others were used for household purposes. The pullets I saved each year for winter laying were invaluable. You may perhaps ask, Where can Dark Brahmas be obtained? As a rule, I prefer purchasing birds rather than eggs for hatching, and now that poultry shows are so numerous, Brahmas are always to be met with at fair prices. For instance, an opportunity will be afforded you at Wolverhampton Poultry Show, to-morrow; or, failing that, there is an excellent newspaper called THE JOURNAL OF HORTICULTURE AND COTTAGE GARDENER, published every Thursday, which treats most efficiently on all matters connected with poultry, and from which you can derive most useful information. In the advertisements you will find fowls of all varieties, and eggs, for disposal, from well-known breeders, and in time you would also find it a very useful medium for getting rid of some of your surplus stock. In thus strongly recommending Brahmas as best suited for farmyards, I do not wish to speak disparagingly of the many other useful varieties of fowls which we have, such as Dorkings, Cochins, Spanish, Game, and Hamburghs; by all means, try them if you like.

But were I a farmer, and wanted a really useful and remunerative breed, for hardiness, fast growing, and sure and certain winter-layers, I would keep Brahmas—Brahmas, and nothing but Brahmas. Another suggestion which I offered was that of keeping some of the best and biggest pullets, and turning down with them a fresh cock. Here I would recommend either Dorkings or Brahmas as being most suited. A friend of mine had a Brahma cock from me two years since for this purpose, and the number of chickens when I last saw his yard might have been described as "legion."

If we look into our markets, I do not think that we find the dead poultry offered there for sale much larger than it used to be, with the exception of Turkeys, Geese, and Ducks, in which I have noticed vast improvement. And here, again, the result of having only first-rate strains to breed from soon shows itself. A good strain will cost no more to keep than a bad one. To show how much Ducks have, of late years, improved in weight, at the last Birmingham Show the first prize Aylesbury Ducks weighed over 18 lbs. the couple. Seventy-two pens of Rouen Ducks competed there, and the first prize couple weighed 19 lbs. 4 ozs. Geese weighed 58 lbs. and 56 lbs. the couple, and goslings of last year 49 lbs. The first prize adult Turkey cock, which came across the Atlantic to compete, weighed 36 lbs. 4 ozs. This bird I believe to be now the property of Mr. Lythall, and with it, if I mistake not, he won the silver cup at Bristol during last month. Both the prizes for Turkey cocks of 1870 went also, at Birmingham, to the same gentleman, with birds weighing 24 lbs. and 23 lbs. each. The old prize hens weighed 35 lbs. and 34 lbs.; the young ones, 31 lbs. and 29 lbs. If you breed from such strains as these, you may go and do likewise. If you make a point, too, of attending some of our largest exhibitions, and mark well the points and characteristics of the winning birds in these breeds you may be desirous of keeping, experience will soon teach you the standard requisite to be attained. Whatever be your breeds of poultry, be careful to infuse fresh blood into them every spring.

As regards the management of poultry, the most important point is to have a properly-constructed, well-ventilated poultry house, with plenty of light, and free from draught. By all means have this before entering upon a fresh breed of fowls, as on their arrival they can be shut in for a few days in their new abode, and thus learn to return to it for the purpose of laying and roosting. Have the door well secured by two flat iron bars to go across it, fastened with staples screwed into the post at one end, and by patent padlocks at the other. There should also be a sliding panel in the bottom of the door for the fowls to go in and out during the day, and the lower iron bar should go across this panel when shut down for the night. You will thus be better able to frustrate the designs of that class of people who hardly know the difference between "mine and thine;" and sly Reynard (however desirous we may be of his welfare) will find it answer his purpose better to visit the poultry yard of some more careless neighbour. The walls of the house should be limewashed at least three times in the year. The perches should not be more than 3 feet from the ground, and ought to be at least 3 inches wide: a larch pole, split in halves, answers the purpose admirably. These perches should be placed all round the house, about 3 feet distant from the wall, not one above the other, and care should be taken that there are no beams or rafters that they can fly up to in the roof, as in their descent they alight on the ground with great force, and this is the cause of so many cocks being bumble-footed and gouty. Round the walls, on the ground, at convenient distances, place three bricks, to form a square for nests for laying and sitting; in these place some hay and a china egg. I prefer this plan to boxes, because they are easier to keep clean, and the other fowls cannot roost upon them to disturb the sitting hens. The centre of the house being an open space, there is room to have the droppings properly raked out from under the perches once or twice a-week, and fresh earth or coarse sand thrown all over the floor, and well raked over. The value of these droppings as manure cannot be too highly estimated. It is usually the plan to allow fowls to roost in sheds, bushes, or trees, where the droppings are mostly wasted, and cannot well be collected and turned to good account. In some places where there is a poultry house the fowls undoubtedly decline roosting in it, because it is kept so dirty, and consequently swarms with vermin. The cleaner you keep your fowl-house the healthier will be your stock. If you can induce your Turkeys to roost in the same house as your fowls, so much the better; and, although it may entail, at first, a little extra expense, by all means have a separate dwelling for your Geese and Ducks. Let the floor be well littered with straw, to be occasionally shaken over, or changed. In winter time, eight o'clock is almost early enough for fowls to be let out of their house, but before so doing it is a good plan to give them a liberal supply of soft food (warm if possible), as it will teach them to become attached to their abode, and the sitting hens will reap the benefit of a regular meal. By soft food I mean potatoes boiled the night before, and mashed up when warm with Indian or barley meal. Corn should be given in the middle of the day, and again before going to roost, in the vicinity of the fowl house. Cabbages should also be specially grown, to be given them daily during the winter months. In summer time they can of course in a measure cater for themselves. The sitting hens will also be much benefited by having a cast iron trough (which will cost about 3s.) placed on two iron brackets, fixed in the wall of the house about a foot from the ground, to contain water, which ought to be changed every morning. As regards the rearing of chickens, I would only say, when under the coop give a most liberal supply, little and often, of different kinds of food, but above all be very particular that the water given them to drink is clear, and often changed. Information you may sometimes require about the management of your fowls and their various ailments, and if you will write to the editors of the paper I have before mentioned, they will, I am sure, willingly give you advice in the columns allotted for correspondence.

In drawing my remarks to a close—though I now assure you that poultry may be made a profitable adjunct to the stock of the agriculturist, and a source of great pleasure and amusement to the amateur, and that with proper care, judgment, and attention it will be exceedingly remunerative—yet I trust that we may, in the course of time, be allowed another discussion on the subject, and learn much by listening to the experience of some members of this club, who may take heed of my suggestions, which, out of pure love for things appertaining unto poultry, have been humbly offered.

Mr. Lowe said that Mr. Brooke had told them that his experience showed that the Dark Brahma were the best kind of poultry for the farmer, but he feared that the price which it was stated three of these birds had fetched—50s., showed that Mr. Brooke must have been looking at the matter from an amateur's point of view. The neglect of poultry by farmers, he considered was due to one of two causes. Either the farms were now on a much larger scale than formerly, or the wives and daughters of farmers did not attend properly to the poultry. Now his later experience was not sufficient to enable him to say whether the Brahma breed would be the best for the farmer to cultivate; but he was thrown back on the experience of the past, when they used to think a Black-breasted Red a decent bird [laughter]. He could remember when those birds would give them a little amusement in the shape of a stand-up fight [laughter]; but in these enlightened days far more healthy pastimes had been introduced. Nevertheless these birds had qualities besides their fighting propensities, and a couple of Game chickens were by no means a bad dish to introduce [hear, hear]. He begged to suggest whether the excellent wives of the farmers and their daughters could not devote more attention to the cultivation of poultry, more especially in the shape of food for the people.

Mr. George Wise said a few years ago, when he lived in Ireland, he was a very great fowl-keeper. He was very unfortunate now with regard to fowls, but he still took a very great interest in them. He took a great interest in the preservation of fowls, looking at it as a fox-hunter. He never lost but two fowls during the whole time he had kept them, and if people would only just take care of their fowls they would not be pestered by people saying, "The foxes are always taking our fowls" [laughter]. It might be interesting to some gentlemen to know that during the five years he kept fowls he always found that he got more eggs in the month of February than in any other month [hear, hear], and the next month he found good for his eggs was the month of July. He always gave his fowls plenty to eat, and fed them regularly, and took as good care of them as he did of himself, and he could only say he found them most profitable [hear, hear].

Mr. Brooke said he must disagree with Mr. Lowe on the point of keeping Brahmas. He had kept Malays for the last thirty years, but he would not recommend them to farmers.

Mr. Lort said he should recommend Malays to farmers. He had kept them, and had found they were the only breed he could keep. They were an excellent breed for the table, and he did not see why Mr. Brooke should not recommend them to farmers. He could not keep Dorkings or Spanish, and yet he could keep Malays. He would be glad if Mr. Brooke would give them his reasons why he would not recommend them to farmers.

Mr. Masfen said he had listened with very great pleasure to the remarks of Mr. Brooke. So far as his remarks about Dark Brahmas were concerned, he was very much disposed to agree with him, from a farmer's point of view, that they were a very profitable breed. That, he thought, was the forty-fourth day of continuous frost they had had, and he was happy to say that it was the only time he had had eggs every day in his life, and these eggs were the produce of the Brahma kind. Mr. Lowe had alluded to the fact of the present generation of farmers' wives looking with contempt upon the poultry [laughter]. He was happy to say that idea did not reign at Pendeford. A statistical account was kept by his wife, and she could tell them what she made out of the poultry in the year. He mentioned also another instance, and said, therefore, he thought his friend Mr. Lowe was going beyond the mark in saying the farmers' wives did not look after the pounds, shillings, and pence in the poultry department.

Mr. Wright said for more than a quarter of a century he had kept poultry, and had had profits to a considerable extent. He considered that they could not lay down any strict rules as to the breed of poultry to be kept universally. There would be differences of climate and of soil, and some would be inconvenienced in the room required for keeping them. With regard to the keeping of poultry generally, he found that they required two runs or two yards for their old and young birds. Unless they were able to provide that accommodation, it was almost impossible they could keep poultry satisfactorily [hear, hear]. They found they cost them double in corn, and in the course of a year or two their old birds became unfit for use. He advocated the use of out-barns for that purpose. But the most important question for them was to consider the best kind for a farmer to keep. He thought Mr. Brooke would give up the Brahmas. One of the best and oldest birds was the Dorking. It was certain the number of eggs they laid was no

equal to those of the Cochin or the Hamburgh, but for the table there was nothing to equal them. Of course in some localities, where the soil was damp, he did not think the Dorkings would do very well. Another objection was they were rather delicate, and liable to have the roup; but this, he thought, arose very often from the overcrowding. With regard to the keeping of fowls, he said he had a very large range for them, and he had the roosting place swept out every morning, and some of McDougall's powder scattered about. He would recommend every stock-keeper to use this for the prevention of disease. He had kept the Hamburgh, and for an amateur there was nothing superior to the Silver-spangled Hamburghs. They laid almost for ever, and for the table there was no poultry that would surpass young Silver Hamburgh chickens. The Game were very fine, but they were rather leggy. They had been known to lay more than 300 eggs in a year. A good deal depended upon their situation. At any rate they were constant layers. He spoke favourably of the old Pheasant fowls, Moonies, or Redcaps, as they were called. Nothing was more worthy of the attention of any gentleman than the old Golden Pheasant. The Cochins, as a rule, were very good for the table, but he complained that they had too much a propensity for sitting. With regard to the Malays, they were a very valuable fowl, and he was surprised they did not receive more attention. Speaking of the question of crosses, he thought it was a mistake; but the best of all crosses was a Brahma and Dorking. He was sorry to say with regard to the Dorking that they did not exhibit so strongly at the last poultry show as they had done. This he attributed to the drought of last year, which caused the worms, upon which the fowls often fed, not to be so plentiful.

Mr. Brooke in answer to the question put to him why he did not mention the breed of Malays, said that they were very long in the leg and looked unsightly in the market, and people would not therefore buy them. Then, again, he did not recommend them to farmers because they were very pugnacious, and it was very hard work to keep peace amongst them [laughter]. After again recommending the Brahmas, he said he had listened with pleasure to the discussion, and he hoped that at some future day they might have more discussion on the same subject.

Nantwich Poultry Show.—I sincerely hope that another year the Committee will open the Show to general competition, and offer prizes which will induce some of our most prominent exhibitors to send, and that the ladies in the neighbourhood will render their assistance, and give cups for those classes which your correspondent considers so miserable. Then, should he favour us with a report next year, we shall hope that his praises may be more evenly divided.—Spectator.

Woodbridge Show.—This Show will take place on the 15th and 16th of March next., and deserves encouragement. There are six silver cups value £5 5*s.* each, and three of £3 3*s.* for poultry, and a point cup of £3 3*s.* is also offered in each section of Pigeons and Cage Birds. The prizes for poultry are 20*s.* and 10*s.*, for Pigeons 15*s.* and 7*s.* 6*d.*, and for Cage Birds 10*s.* and 5*s.* If desired, money will be paid in lieu of a cup. There are twenty-three classes for poultry, fourteen for Pigeons, and sixteen for cage birds.

CRYSTAL PALACE CANARY SHOW.

I should like to have given a more extended notice of the Norwich variety than I had time to do last week, the entries in the eight classes apportioned to them including, as they did, more than one-half of the entire number of birds exhibited in the thirty three classes of Canaries proper and Mules, but I was very tired. I had had a busy day. The notes I had scribbled on the margin of my catalogue on Saturday were some not very legible, and others not very clear as to their meaning, and I had paid a flying visit to the Palace to refresh my memory, and take a final peep at the gems of the year. No great undertaking certainly; but why did I leave home in tight boots? At my time of life I ought to have known better. I was very jaded when I returned to my hotel, and the bare idea that the printer was waiting for "copy," and that I might at any moment receive a visit from one of his imps, was in itself quite enough to paralyse my energies. Besides, there was what we call in the north, a meat-tea waiting for me. A meat-tea is tea with "something to it," and my something to it was a steak. Those who thought my last week's notes not equal to the subject must make allowance for human weakness. I handed my hasty memo to the imp in attendance, who, by the way, was not an imp at all, but a most courteous member of the staff at No. 171, promising to—"supplement them next week." That was his composition, not mine; but when I saw it in print on Thursday I thought it read very well. I think it's very neat.

I was not sorry to have had some sort of excuse for paying my second visit to the Palace, and was well repaid by meeting friends I know only by name, as well as old faces I had not seen for years. Before leaving—and it's hard work to get away from the birds while there is any light to see them—Mr. Bemrose and Mr. Walter, with Messrs. Cockle & Watson, "shed a tear" with me at the extreme end of the Tropical Department, where the thin slices of ham are spread out on cold marble slabs to bleach. We had a deal to talk about and not much time to do it in, and with many regrets that there is not a British National Canary Society of gentlemen, holding its annual show in various towns in England in rotation, and having its annual meeting of parliament, we said good-bye, longing for the time when the fancy will take the matter up in earnest, and carry out a project as simple in itself and in its working as A B C.

Mais revenons à nos moutons. The Show was not held in the Tropical Department as of old, but in an elegant tent or awning erected in the nave between the transept and the Christmas tree. The arrangements were excellent, and inasmuch as the unbroken area allows of a more regular and systematic grouping of the cages than is practicable in the Tropical Department, the tent is in this respect the better place; but, I think, in this respect alone. Exhibitors, I was told, were much pleased with the arrangement, as well they might be, for the subdued light would add many shades of colour. As far as judging is concerned, the light was "as fair for one as another;" but that is a wrong principle to start with. I have no hesitation whatever in saying that many birds bought under the shade of the tent would not have been recognised by the uninitiated when exposed to an open light. Undoubtedly it is to the interest of dealers to have their wares shown to the best advantage, but the Crystal Palace Canary Show claims to be something more than the great market it is. The Tropical end was beautifully warm. That is the place for the Show. Any screen arrangement which can be devised to keep off draughts I should cordially approve of, but by all means have a clear light. How the Judges managed without taking the birds from under the awning I cannot imagine. They must have had a very arduous task.

Before passing to the Belgians in my promise to "supplement my remarks," I revert to the Norwich birds just to say in general terms that Derby seemed to be somewhat out of form, Norwich was in force, Northampton came up smiling but a little exhausted from loss of blood, and Coventry showed its ability to fight in any arena.

There was only a very small entry of Belgians. The *Daily News* of February 11th said, "France and Germany are scarcely represented, and Belgium sends fewer birds than usual." I don't think the *Daily News* is in the fancy. The importation or non-importation of Belgian Canaries is not the cause of the paucity of entries. There are plenty of Belgians, first-class Belgians, in the country; but it is a great risk to send such delicate fragile things from home at this season of the year, to say nothing of six days' exposure in open wire cages. I am not referring to birds such as some I saw in Classes 9 and 10. I mean Belgians. No bird is so sensitive, or suffers so much from the exposure and excitement of a show as a high-bred Belgian. I use the word excitement advisedly, for I have seen specimens the centre of such a circle of attraction, that the poor things were being "put up" throughout the entire day, and had scarcely any time to eat a grain of seed. But then they were Belgians, and not things as devoid of shape as Adam's inexpressibles. The classification, too, has something, nay, a great deal, to do with the slack entry. I have before enunciated my opinion on this matter in the columns of the Journal, an opinion which I believe is entertained by most admirers of this remarkable bird. In brief, I maintain that it is essentially a position bird, and that colour is a secondary point; that the presence of a simple *bonâ fide* tick (not a blotch—every fancier knows what I mean), is no detriment whatever to a Belgian; that the highest-bred clear birds will throw ticked young ones; that both clear and ticked belong essentially to the same school; and that if there be not a separate class for the ticks (for which there is no real necessity), both should compete in the same class. The Variegated Belgian is another bird altogether. The marking has been imported from some other variety, and though perhaps nearly all trace of the cross has been bred out, still the cross is there precisely the same as among some of the variegated Cinnamons till recently in vogue among north-country fanciers. I have seen Cinnamons, selfs and variegated, as high up in Belgian properties as many so-called Variegated Belgians. To class ticked birds with these is manifestly absurd, since they belong to two different classes; but if they be, however much at variance with common sense, grouped together in one, and yet have to be contented with two prizes while less comprehensive classes have three, one cannot help tracing the small entry to causes other than those assigned by the *Daily News*. The best bird in the four classes was No. 328, a good bird, J. N. Harrison. Mr. Doel's were in Norwich cages, and seemed afraid to stand up. No. 340, G. Tuckwood (who knows a good bird and spares no trouble to get it), was more massive in the shoulder than most of its compeers. Mr. Poole, of Notts, was second in the clear classes with birds of no great merit. I tried them all, but could develope no great beauty in any. The subscription list for the cup for this variety did not fill, neither did that for the Norwich, which is a thing "no fellah can understand."

The London Fancy made a brilliant show with thirty entries, among which the well-known names of J. Waller and W. Brodrick were conspicuous. In Jonques Mr. Brodrick showed two, and was first and highly commended, while Mr. Waller was second, third, and very highly commended with the remaining five of his seven entries—a great performance. In Mealies Mr. Waller was first and carried off the cup, which the half dozen enthusiastic admirers of this remarkable variety had no difficulty in raising, with a glorious bird well moulted, though I fancied it had a foul feather on each side of the tail. I do not say this as reflecting on the Judges, for even if it were so there were no doubt sufficient counterbalancing points to enable it to occupy its proud position, and they would have a better opportunity than I for careful examination. Mr. Waller's remaining four birds all re-

ceived the highest commendation, Mr. Brodrick being second and third with his two entries, the whole being birds of great quality, rich colour, and excellent feather. It may be that many, when looking at the London Fancy Canary, are not aware of the peculiarity which attaches to it, and the extreme difficulty in bringing it out in show condition; and it may be matter of surprise to some to know that those deep orange birds with their jetty black wings and tail are, when in their long clothes, not more comely than a hedge Sparrow, and it is not till they are short-coated that they change their sombre garments for that rich jonquil dress which contrasts so strikingly with its black trimming. This costume they wear for only one year, for at the second moult, when they, in common with other birds, first change their wing and tail feathers, the black is replaced by white, or at best by grizzly grey, and the bird retires from the scene of his victories into the more sober quiet of domestic life, spending the remainder of his days in his homely suit, while his olive branches grow up about him clad in the fashionable attire of his early manhood, only in their turn to undergo the same remarkable metamorphosis.

This tendency to change of colour is to some extent shared by the Lizard; and as it is with some a question whether a greyhound is a deteriorated bulldog, or *vice versâ*, so it is a moot point with many whether a Lizard be a degenerate London Fancy, or a Fancy be a degenerate Lizard. They have some points in common, and are occasionally crossed, as is evidenced by entries in the "Any variety" class, but not to the extent some suppose. Though a great admirer of Fancies, I am not a breeder of them, and so can say little as the result of my own actual experience. I do not call a man who buys a pair of Fancies and rears a nest or two a breeder proper. It is from such men as Mr. Brodrick and Mr. Waller, who have made it a life study that we must be content to learn; and Mr. Waller assured me in a most interesting chat I had with him, that it is not a practice to cross the Fancy and Lizard, that the deep black wings and tail have not been derived from the Lizard, but are native to the bird, and that by judicious pairing London Fancies will continue to produce such birds as were at the Palace without any foreign admixture whatever.

Fifty-one Lizards were staged, Mr. Ashton being first both in Gold and Silver-spangled. The cup was awarded to No. 403, the Golden bird, but I inclined in favour of No. 425, than which few finer Silver-spangled Lizards have been seen. I say it modestly, having no wish to rub anyone's hair the wrong way. The cup bird was certainly beautifully spangled, well capped, though slightly defective in one eye, and just a little uneven at the back, and very bright, and clearly merited its position at the head of the class; but the Silver-spangled gem was well calculated to make one break the tenth commandment. Mr. Judd was a good second in the Golden class, with a finely-spangled bird, though a little run on the flights, and Mr. T. W. W. Fairbrass, of Canterbury, third with a strong lusty bird also slightly run. All his birds showed that rich bronzy tinge so much desired by Lizard fanciers. I do not want to be taken to task for adopting the word "bronzy" as conveying my idea of the shade of colour I refer to, but I use it as opposed to that greenish tinge which is often present. No. 397 (Fairbrass), a hen, was claimed at 50*s*. I observed no commendation attached to her, but I thought her a remarkable bird. Mr. Tuckwood's birds also were of the right stamp, and altogether it was an excellent class. In Silvers, Mackley's second pleased me much. Not so No. 409, third prize, which though rich in colour was not remarkably well mottled. Nos. 410 and 411, G. Harrison, were good, and 422, Fairbrass, not mentioned, was a fancy of mine. I apprehend that the defect in the front of the cap was a bar to its commendation. To No. 424, Adams & Athersuch, I find I have appended the remark, "high colour, fine cap;" and to 426, Ashton, "in a cloud:" it was very much run, and as compared with 422, not worth its diploma.

There were only two prizes to each of the three classes of Cinnamons, numbering in all seventy entries, an inconsistency which I have no doubt will, with other defects, be remedied next year. Northampton as usual was strong, Mr. Irons taking first in Jonques, and Mr. Tomes second with a bird which, I think, was beyond compare its superior. I blame the awning for it. No. 430, Gayton, and 445, Spence, were very even in colour, a great point in Cinnamons, for with high colour comes an objectionable stripe, the presence of which is an eyesore to the fancier. Mr. Waller showed three birds not to be despised, which were soon claimed. No. 444, H. J. Ims, very highly commended, was a mistake of the tents. Mr. Waller was first in Buffs with a great bird, and Mr. W. Gamble second with an unmistakeably fine specimen, with Moore & Wynn and the other Northampton representatives close up. The tent was wrong again with 477, J. Hadland.

The awards in the Marked or Variegated Cinnamon class were made on a plan altogether different from that adopted last year. The object of this class, what is to be aimed at, should be more clearly defined; "Marked or Variegated" is very vague. However, assuming it to mean, when applied to Cinnamons, a bird having cinnamon markings, the question is, Should the bird be judged for general style and quality apart from the regularity of the markings? or is exactness of marking to be considered of as much value as in an Evenly-marked Norwich? Last year high-coloured, irregularly-broken birds scored the highest honours above others marked with great exactness. This year the case was reversed; exactness ruled to the subversion of colour and quality if combined with irregularity. The fact is, the two classes are as wide apart as the poles. The one is the result of crossing with the Norwich to obtain colour with as little disposition to break as possible; the other is the result of careful crossing with Belgians, with especial care to retain a disposition to break into regular markings. The type of the one class is a bird of Norwich build, having a rich body colour, with patches of cinnamon here and there; the type of the other is a long, slim, graceful bird, evenly marked on the wings and eyes, in which colour has, to a great extent, been sacrificed for some approximation to a fixed character for shape and exactness of marking. Such a specimen was No. 482, Bemrose & Orms, first prize, and were such clearly understood that to be the recognised standard, many a beautiful bird of that stamp would be sent from the north, where the Cinnamon has for years been grafted on the Belgian to attain similar results. No. 485 (H. Apted) may be accepted as a good example of the Cinnamon Norwich, an intermediate step between the old Dun and the modern school of bright Cinnamons so deservedly popular.

The Any other variety class was not very interesting, but it contained one or two good samples of the Manchester Coppy, with one of which Mr. Ashton was first; two good Marked Yorkshire, 500 (Stansfield), second, and 508, Hawman; one solitary Glasgow Fancy, No. 510 (Baxter), third, a good representative of the graceful favourite of the other side of the Tweed; and divers nondescripts, among which one figured as a "Green Hybrid" (?), and four were described as "Buff and Yellow" (?).—W. A. Blakston.

IS THE RABBIT FANCY ON THE DECLINE?

No; but, on the contrary, steadily increasing every year. Just refer to "our Journal" of December 15th, 1870, and read the report on the York Shows, from their first one in 1864 to that held in 1870, and it will be found that in the first-named year there were only fifty entries of Rabbits, while in the last year the surprising number of 124 entries were made. Can anyone, with such an instance as this before him, say the Rabbit fancy is on the decline? The York Show is not the only case I could quote.

Mr. Millington may continue his notes about the value and scarcity of the Lops, but he will not thus better their position in the various prize lists, much less by saying that the fancy kinds are so cheap and so very plentiful; on the contrary, he has materially aided me in my endeavours to get the varieties better classed, and to the Lops he has given rather a sore hit. For any committee to offer more prizes for a scarce variety than for a plentiful variety would be out of all reason, for committees generally offer most to those which secure the most entries.

As to the club, I think it an excellent suggestion, and am ready to do all I can to further the proposal. I would suggest that the subscription be 5*s*. instead of 1*s*. annually, and that whenever a Rabbit show is held, a member living nearest the show should have his expenses paid to look after the members' Rabbits only, and see them fed and properly repacked for home.—Jas. Boyle, jun., *Blackburn*.

THE GREAT BUSTARD IN WILTSHIRE.

A Great Bustard has recently been killed on the old haunt of that bird—Salisbury Plain. I notice that in some of your contemporaries it is stated that no bird of this kind has been seen in Wiltshire for fifty years. I am in a position to state that this is incorrect.

In January, 1856, a male Bustard was wounded by a shot from one of Lord Ailesbury's keepers, and two days afterwards was, strange to say, captured by a little boy of only seven years old. It was subsequently purchased by my late neighbour, Rev. G. T. Marsh, the Vicar of Sutton Benger, Wilts, in whose valuable ornithological collection I have very frequently seen it. At Mr. Marsh's death, in 1862, it became, I believe, the property of his brother, Mr. Matthew Marsh, late M.P. for Salisbury.

The particulars of the capture of this Bustard are so singular that I will relate them, as they may interest some of your readers. The keeper shot at the bird whilst it was flying, not knowing what bird it was, or ignorantly fancying, as it was such a large bird, that it must be an eagle. The distance was great, and as the bird flew on apparently unharmed the keeper thought no more of it. A few days after a little farm boy aged seven saw a large bird laid down and fluttering in a turnip field. The lad, a brave little lad, caught it by one wing, and dragged it (the bird was weak with hunger and loss of blood), across the field for a quarter of a mile, and took it to a barn, where a man broke its neck. The labourers in the barn had just come in to dinner, and wanted to pluck and dress the bird for that meal. However, the lad stalked off with his property on his back, and sold it for one shilling. My friend Mr. Marsh was glad to give twenty sovereigns for it a little time afterwards. I have often looked at the bird with great interest, and wondered how a little fellow dared to capture it, for it measured from wing to wing more than 6 feet.

I knew two other gentlemen who had seen Bustards in Wiltshire. The late Rev. Robert Ashe, the Rector of Langley-

Burrell, caught a young one, and tied its legs with a pocket-handkerchief, and hid the bird in a hole until he had taken Divine service, but afterwards found neither bird nor handkerchief. The late Mr. William Lanfear, of Christian-Malford, had also seen more than one on the Plain, and one that was captured and kept for a few days by a cottager in a pigstye.

Indeed, it is a mistake to think that no Bustards have been seen or killed of late years. One was shot in Cornwall in 1843, and one near Stonehenge in 1849. Recently Bustards have been seen, I believe, in Yorkshire, as well as in Wilts. It seems strange that they always are found in those counties in which they once were common. Then, it is odd that now all the country is divided into farms, and on farms labourers are constantly working, yet, save now and then, Bustards, birds as big as Turkeys, are not seen. How to explain this I know not, and that Bustards could fly over the sea is out of the question, and if they could they would be seen in Kent or Sussex. Must it not come to this—that a few birds, though under great disadvantages, still exist, and breed, and bring up a very few young ones?—Wiltshire Rector.

UNICOMB HIVE.

In reply to "An Amateur Bee-keeper," who requests some information respecting the construction of a unicomb hive, I think I may be able to render him some assistance by giving a rough description of one contrived by myself two years ago, and which, in practical use, answers remarkably well.

The first object which should be aimed at in one of these interesting appendages to an apiary, should be the greatest possible facility for peopling it either with a swarm, or with the contents of an established stock. The second should be, that when not further required for observatory purposes, or in order to save the colony through the winter, the combs and bees may very readily be transferred into quarters more congenial to their natural instincts. To carry out this principle, I decided on adapting the interior of the hive for taking the moveable bars and combs from my frame hives. Great care was requisite to insure that the various measurements were made correct, and that any bar from any hive in my apiary should be capable of being slipped into or out of the hive in a moment.

After some consideration, I decided on having a long shallow hive instead of a deep one, and planned it to take three full-sized combs in length, by two in depth.

The bars of the frames used by me are nearly 14 inches in length; the depth of the combs when fully worked in the frames is about 8½ inches. The length of the hive measured from outside to outside, is 3 feet 10 inches, and the depth nearly 1 foot 10 inches. The frame is constructed of 2-inch plank throughout, rabbeted so as to form a series of recesses for the doors and glass sides, and the comb-bars to fit in.

When the glass sides are *in situ*, the distance between the two glasses must be exactly 1⅛ of an inch, or not exceeding 1¼ of an inch. For these sides light wooden frames without divisions are made, into which are fitted entire sheets of good, thick, clear glass, held in without putty by narrow slips of wood. These glass sides have no hinges attached to them, but are simply slipped into place, and secured at the top by small buttons, similar to those used for the inner part of writing desks, and at the bottom by two small sliding brass bolts, shooting down into the floor-board. A couple of small picture rings attached to the bottom rail of each frame will facilitate their handling.

The top, sides, and bottom of the outer hive are all morticed together, the bottom being 2 inches wider all round than the top and sides.

The outer wooden shutters are made in halves to meet in the centre. They are framed and panelled; the panels being of the same thickness as the frames—viz., ⅞ inch when finished. They are hung on shifting butt hinges, so as to be easily slipped off or on, are fitted with sliding bolts, and secured by locks. The entrances, 4 or 5 inches long, by ⅝ inch high, are cut in the thickness of the floor-board on either side, sloping up and meeting in the centre of the interior, where they are opened out. An alighting-board is also attached to each side. Blocks of wood are fitted to slip into either of the entrances when the hive is turned round for observation.

The hive revolves, having an iron pin attached to the bottom, fitting into a socket let into the top of an octagonal pedestal. Turning to the section of the interior, *fig.* 1, we find that the upper bars do not touch the top, but have a space of ⅜ of an inch between them and it. This serves two purposes—first, it brings the upper parts of the combs down nearly level with the highest portion of the glass; second, it allows free passage to the bees over the combs, an advantage for work, and useful when feeding. An aperture 2 inches long by ¾ inch wide, is cut through the top for this purpose, and for ventilation. Four side apertures are also cut, being closed with perforated zinc

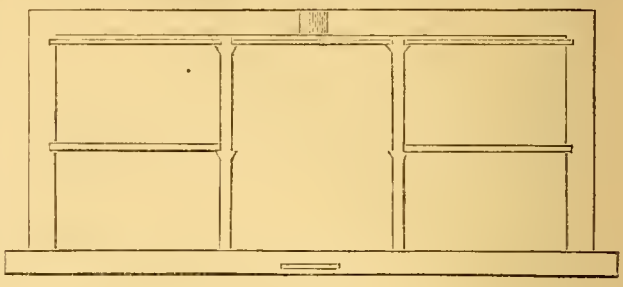


Fig. 1.

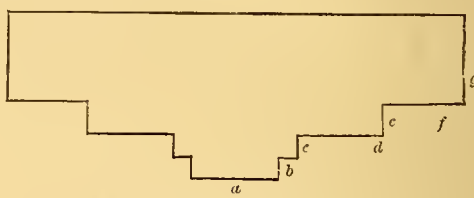

Fig. 2.—2⅝ inches, one-half the actual size.

a. Projection for combs, and rests for bars, 7-8ths inch.
b. Rabbet, ¼ inch.
c. Ditto for glass side to fit against, ⅝ inch.
d. Recess for glass side, ⅜ inch.
e. Rabbet for wooden shutters to rest against.
f. Recess for wooden shutters, ¾ inch wide.
g. Side of frame, ⅝ inch.

when the bees are confined for exhibition at a flower show or other occasion. When not so required, blocks of wood are made to fit them. Two uprights are necessary to serve as supports for the comb-bars. These are ¾ inch wide, by a general thickness of ⅝ inch, but they are made thicker just under the ends of the bars so as to form rests.

The distance between the bars when in place is exactly 8 inches. This is narrower than the interior space of the frames, the object being, that when combs are shifted from the frames into the unicomb hive, the bottoms of the upper row of combs shall reach to the tops of the second row of bars, for the double purpose of security and appearance; besides which, if there are spaces between the combs in the centre of the hive, the queen will constantly be slipping through out of sight. The space below the middle bars is 8½ inches. An ornamental roof made sufficiently roomy to allow of a feeder being used fits on the top of the hive.

I have hitherto described the hive as I have constructed it, but it is not necessary that the shape or dimensions I have given should be adhered to. If preferred, the hive may be made deeper and shorter—that is, to carry three rows of bars in height, by two in length. Or if thought to be too large for the district, or the requirements of the bee-keeper, a hive intended to carry four bars only may be constructed.

If "An Amateur Bee-keeper" uses the Woodbury hive, I should recommend him to alter the measurements I have given, so as to adapt his hive to the use of the Woodbury bars. If he does not work bar or frame hives, he can make his unicomb hive to carry bars of any length he pleases. In the latter case he will require a box hive to be made, holding the same bars, for the purpose which will be described.

We will suppose that the Woodbury bar-and-frame hive is in use in his apiary, the bars, of course, being loose in the frames. One of these hives being properly prepared and furnished with nice guide combs, a swarm is shaken into it in the usual way, and allowed to work for two or three days. The hive is then opened, and the combs inspected, any irregularities being remedied. It is a good plan to alter the position of the combs in order to compel straighter work. The bees are allowed to remain in this stock hive for a few days longer, and then the unicomb hive being brought to the same stand or locality, the outer doors and the glass frame of one side are removed. The stock is placed close by the side of the unicomb, the bars are carefully lifted out without shaking off the bees, and slipped

into their respective grooves or rests. Those combs containing the most brood are selected for the central portion of the observatory hive. When all the combs that can be inserted are put in it will be necessary to see that they rest evenly, and as soon as possible the glass side should be slipped into place gradually, using very little pressure to allow the clusters of bees to disperse a little before finally pushing in. This being done, run in the bolts, and hang and close the outer shutters. Shake off any bees that may be loitering in the stock hive, remove the box out of sight, and the bees will soon find their way into their new domicile.

If "An Amateur" should not be in the habit of using bar-hives, he must make a simple box to receive the bars of his unicomb, and in this case he need not be particular as to the length of the bar he chooses. He would find four bars of 16 inches in length and made to carry combs of 9 inches in depth, would make a very nice-sized unicomb. In other respects he may follow the directions I have given.

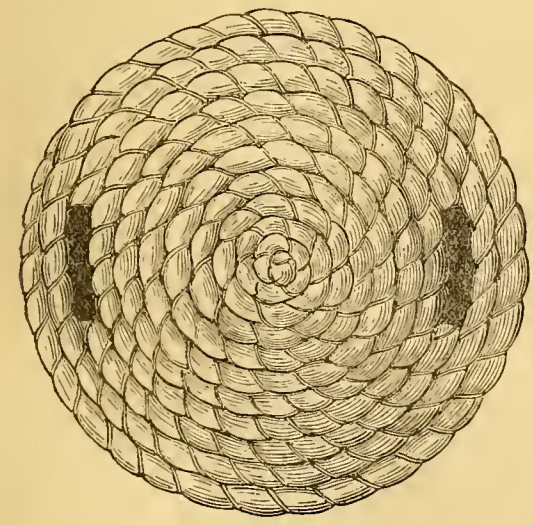
Towards the close of autumn, or when the observatory hive is no longer needed, the outer doors are unhung, the glass sides removed, and the bars, combs, and bees transferred into the stock box, which must occupy the same position as that to which the bees have been accustomed. It will generally be necessary to afford the bees a liberal supply of artificial food, or a full comb or two from another stock may be given. I omitted to say that when bar-and-frame hives are in use in an apiary, an observatory hive constructed on this principle may be stocked at a moment's notice. It is only necessary to visit any prosperous stocks, and to remove the requisite number of combs and bees.

I hope the description and directions given will be sufficient for the guidance of "An Amateur Bee-keeper," but if he should require further information I shall be happy to assist him to the best of my power.—S. Bevan Fox, *Exeter*.

THE ECONOMIC, A NEW DEPRIVING HIVE.

One of the objects which I have had before me in bee-keeping has been to improve the system as generally practised amongst my neighbours; but hitherto the great hindrance has been the want of a really good depriving hive at a moderate price—a want frequently expressed in your Journal.

In conjunction with Mr. James Lee, of Windlesham, I have endeavoured to supply this want by introducing a hive at a moderate price, combining all the most recent improvements. The lower part, or stock-box, is simply a well-made round straw hive with a flat top like Payne's, but with no hole in the centre, the communication with the super being removed from the centre towards the sides of the top, as in the accompanying



figure, thus removing the great objection to Payne's hive, the liability of the queen ascending into the super and depositing brood, it being now a well-ascertained fact that she is most unlikely to ascend where the communications are at the sides of the top.

The great difficulty in making the openings at the side of the top was to avoid weakening the crown of the hive, and to get a perfectly even surface to allow of the true adjustment of the adapting-board. This, of course, has holes corresponding with those in the straw, is wasp-proof, and may be of any shape. In the present instance it is octagonal to correspond with an octagonal super. Perhaps it would be as well to fasten down the adapting-board permanently with brass screws before using the hive. This octagonal super is of wood, 13 inches wide by 5½ deep, inside measurement, and has two small windows to show when the comb is sealed, is fitted with moveable ribbed bars as in the Woodbury supers, and like them has a glass top in a wooden frame, which affords a good view of the super. This top can be removed for the abstraction of the combs.

As regards the price, Mr. Lee will supply the complete hive, including straw stock-box, floor-board, adapting-board, and octagonal as above, at 10*s*. 6*d*. Considering its many advantages and moderate price, we have named it, by way of distinction, the Economic Hive.

Another consideration in view in the construction of this hive was to meet the wants of those who cannot afford a shed or the protection necessary for a wooden hive. This hive may be sufficiently protected by an American cheese-box and the old-fashioned milk-pan. These should not rest immediately on the top of the hive, but be slightly raised by small blocks of wood to allow the air to circulate between them, in order to keep the hive cool. At the same time there is nothing equal to a shed open in front, if it can be had or conveniently placed. All depriving hives require as much shade as possible, especially from midday and afternoon sun.

Lastly, to meet the wants of those who cannot afford 10*s*. 6*d*., Mr. Lee has agreed to sell the straw hive constructed on the above principle separately at 2*s*. 9*d*., or 15*s*. the half dozen. With this as a basis, any man of ordinary intelligence may easily construct a perfect depriving hive. A piece of wood for an adapting-board is easily obtained, and boxes of all shapes and sizes may be had at a very moderate price at the grocers'. A lady sends me all her milliner's boxes for the purpose. If preferred, two supers can be used side by side, the second being put on when the first is half filled with comb, or when the bees seem to require more room.

For further particulars about the Economic Hive I must refer your readers to Mr. Lee, whose advertisement appears in your columns.—H. C. Ripley, *Burton Abbots Vicarage, Oxon.*

OUR LETTER BOX.

Caponising (*Alpha*).—It is a cruel, dangerous, and needless practice. Cramming is equally so, for a fowl cooped and fed naturally on nourishing food will fatten in a few days. The town you mention is surpassed by others since the introduction of railways.

Brahma Hens' Backs Featherless (*G. R.*).—In other breeds we should say that their mates had pecked them, but that is unusual with Brahmas. If the swelling and redness are in what we should call the abdomen it is perhaps natural; but if it be all round the insertion of the tail, then their companions have had to do with them, and all you can do is to separate them. Rub the bare places with compound sulphur ointment, and give the birds plenty of large sods of growing grass cut with 3 or 4 inches of mould. They eat the feathers because they lack something their runs do not afford.

Dark or Light Brahmas (*Woodlark*).—There is no difference in the Brahmas except the colour. The Light have the same properties as the Dark, and in some shows they have been equally numerous. It is wicked and unprofitable to stop the desire to sit in a hen, and it is almost impossible. Every man thinks the world was made for Cæsar, and that he is Cæsar. A man asks whether, if he pick the breast of a hen and whip it with stinging nettles, it will make her sit!

Scurf on Cochins' Legs (*Lemon Buff*).—We do not believe it to be infectious, but we would not risk it. Sulphur ointment is the application for it. Canary seed and millet in the spray are the best food for Grass Parakeets. They like green food.

Pheasants are not Poultry (*W. F.*).—For a cup to be awarded for the most points in poultry, Pheasants ought not to be allowed to contend.

Diseased Dorkings (*A Constant Reader*).—They have diarrhœa, caused probably by the changeable weather. Give each fowl five grains of powdered chalk, one grain of opium, and one grain of powdered ipecacuanha twice a-day until the looseness is checked, accompanied by a warm soft diet, such as oatmeal mashed with a little warm ale.

Judging Brahmas (*J. L.*).—It is impossible for us to give the reasons for the awards made by the Judges. The single fact that we know nothing of the competing pens or their merits would prevent us. But, speaking of general ideas, we have no reason to be silent. In an open class, where all ages come into competition, a careful judge should weigh the merits of each, taking age into consideration. The young should not suffer from their want of age as compared with their elders. It is their disadvantage that they have no class for themselves. Mere weight should not decide, because the chickens in that point cannot compare with adults. The latter have an advantage in their freshness and the beauty of their plumage. These points should be allowed as a counterpoise to those parts that are the peculiar properties of age. We do not believe that any of our experienced judges pass over chickens because they are chickens, and we think you will do better to agitate for separate classes rather than withdraw from exhibiting.

COCHIN'S COMB TIPS WHITE (*E. D W.*).—The cock's comb is frozen. Rub it thoroughly and frequently with very strong camphor ointment.

BREEDING BLACK HAMBURGHS (*Black Hamburgh*).—We are unable to give you positive answers to your question. With regard to mating your birds, you must buy your own experience. Birds take, as a rule, more after the hen than the cock. Presuming you have cocks and hens of the Black Hamburgh well bred on each side and of different strains, we advise you to mix the two, putting in each case a cock of different strain with the hens. In these manufactured breeds it is not necessary constantly to have recourse to the component parts. It is only when some essential property appears to be dying out that a bird possessing that particular point should be introduced. If we had two pens intended for the manufacture, we should put the darkest Golden-spangled Hamburgh hens we could find with a Spanish cock, and the darkest cock with Spanish hens; we should then interbreed with the produce. If you are bent on making your own birds you can do so, but where there are so many good specimens to be bought we are inclined to think "*le jeu ne vaut pas la chandelle.*"

MATE FOR A LEMON BUFF COCHIN COCK (*Alpha*).—You do not tell us the bird you wish to produce. If Silver Cinnamon, put hens with French white bodies and light brown necks. If Buff, take hens or pullets of one entirely very dark buff shade all over. There must be no mixture, or it will perpetuate the mealy wing in the cock. If Lemon, choose lemon, but without a lighter hackle. Give your sick fowls some chalk pounded and mixed with their food.

DORKING CHICKENS' TOES DISTORTED (*B. B.*).—We cannot tell why the toes of your chickens turn the wrong way, unless they are kept on an improper floor, such as wood, stone, or brick. If they are, either remove them, or, if that is inconvenient, cover the flooring with dry dust or road grit some inches thick. If there be no reason of this sort, we should say, at any rate, they will grow up so slightly deformed as to cause it to be immaterial at an exhibition.

FOWLS FOR EGG-PRODUCTION (*Kettering*).—Pencilled Hamburghs lay a large number of eggs. They did so in this case, as we consider the number you have named a large result. We know none that would lay more, but some would lay them larger. Brahmas, Spanish, and Crève-Cœurs are all good layers, and do well in confinement. The two last lay very large eggs.

FLOORING OF A POULTRY RUN (*E. M.*).—The flooring of the house should be of hard earth, the rest of the run, earth; in one corner a heap of road grit, in the other a heap of bricklayers' rubbish. Fowls in confinement should have as often as possible, sods of growing grass cut with plenty of mould to them. Give barleymeal instead of whole corn. The kitchen scraps are good. Potatoes are not so.

CROSS BETWEEN BLACK HAMBURGH AND BLACK GAME (*T. B.*).—If you breed as you propose, we believe you will have some very good Black Hamburghs among the produce. You must expect a good many single combs, and must not breed from them again.

OATMEAL (*W.*).—We hope to give the information shortly.

GROUND OATS (*Oxoniensis*).—The sample you enclosed is food spoiled. The oats we spoke of are ground, husks and all, so fine that they mix up into a paste without any appearance of bran. We bought them for years of Mr. Agate, Slaugham Mills, near Crawley. We do not know whether they are to be had there now or not, but they are largely used in Sussex. We are told it is necessary to have stones dressed on purpose to grind oats sufficiently fine for poultry food. Fowls will not eat such as you enclose to us, nor will such mix. We hope shortly to be able to give an address where a better sample may be had. We cannot tell you where you should buy Scotch oatmeal.

CRUSHED OATS (*H. J. O.*).—Whether damped or dry, they are more nourishing for fowls than pollard.

CARLISLE SHOW.—Mr. J. Mashiter, Ulverston, sent a Brown Red cockerel and pullet (Class 36), and has had a Brown Red cock and hen returned—"I find I have taken prizes under the name of S. H. Stowe, in Dorkings, and Rouen and Aylesbury Ducks.—S. H. STOTT, *Rochdale.*"

DUCK'S EGGS DISCOLOURED (*C. F. F.*).—The eggs are faulty, because the Duck is out of health, and her secretions are at fault. The proof of it is patent. You have two Ducks both treated alike; one lays good eggs, the other bad ones. It is, then, from no general cause. Catch her, shut her up, and feed on oats mixed in a shallow vessel with growing sods and gravel. Feed sparingly.

EGYPTIAN RUNTS (*W. M.*).—We have seen Runts brought straight from Egypt, they were white in colour, and had the appearance of English Runts, only smaller. Very probably they were what English Runts were until bred to vast bulk as fancy birds. It would be a gain, regarding Pigeons in a commercial sense, if a smaller and prolific Runt could be generally cultivated, as the fancy birds are the reverse of prolific.

FLYING TUMBLERS (*X. Y. Z., Hull*).—1st, Your Pigeons never could have tumbled, as they certainly would not have lost that power. After being shut up, Tumblers on being let out always fly and tumble prodigiously. 2nd, The eggs will not be affected beyond the first pair. We have tried it constantly.

CANARY NOT SINGING (*Idem*).—Most likely your bird is covered with red mites, and so out of health. If the cage is old burn it. Then dust sulphur in the feathers of the bird.

CANARY MANAGEMENT (*Several Correspondents*).—We hope Mr. Blakston next week will commence a series of papers upon the subject.

CANARY'S HEAD SCURFY (*C. H. Butler*).—Rub the part affected with a small piece of fresh butter or sweet oil, and supply the bird with green food as soon as it can be had. In place of chickweed give watercress, the heart of a cabbage, a piece of apple, or loaf of lettuce if any can be obtained.—W. A. B.

CANARY'S SKIN IRRITATED (*Ridiculus Mus*).—Discontinue the hemp, and supply with such green food as can be procured at this season. *Vide* reply to "C. H. Butler." Add linseed and summer rape to his Canary seed. Use the bath frequently, and keep up a low temperature.—W. A. B.

PARROTS MOULTING (*H.*).—Warmth and extra nourishment are indispensable. You should alter the food thus, according to an authority on the subject—"Hempseed and Indian corn given separately, each twice a-week, bread and milk, with a few chilies cut small once a-week. On the seed days a little saffron steeped in the water. If great difficulty in the moult, give captain's biscuits soaked, and made hot with cayenne, about three times a-week, and put some liquorice in the water." If the moult goes on quite favourably, and the bird appears cheerful, but little alteration from the common diet need be made, warmth is the great requisite.

CONSERVATORY AVIARY (*Canary*).—A conservatory is not a good place in which to breed Canaries. The better plan is to fit-up a room for the purpose. Put-up the birds early in March, but much depends upon the state of the weather, situation, aspect, &c. As a rule, there ought to be no young Canaries till the old ones can see to feed them at six o'clock in the morning.—W. A. B.

A HIVE'S PROSPECTS (*P. F. L.*).—The stock appears to have gone through the winter in good condition, and you may therefore fairly expect one or more swarms in May or June. These you can place in such a description of hive or hives as may best please you; or you may, if you prefer it, try working your stock on the depriving system by cutting a 3 or 4-inch hole in the crown of the straw hive with a penknife, and cementing thereupon with good mortar a wooden platform (which should be clamped to prevent warping), of sufficient size to accommodate an adequate super.

EMPTY WHITE COMB.—*Jane* is anxious to procure some empty white comb to put into glass supers. She will, therefore, be much obliged if anyone will send her some, or let her know where she can procure any. She will send a post-office order or stamps in payment. Her address is at the office of this Journal.

REMARKS.

15th.—Rain began at 9 A.M., but only a few drops fell; a dull day.
16th.—Dull day, except a little sunshine about noon.
17th.—Fine mild morning.
18th.—Fresh wind after 5 P.M.
19th.—Very fine till 5 P.M., shower, damp evening; gale at night.
20th.—Fine breezy day, shower 11.25 to 11.40 A.M., fine sunset.
21st.—Very fine morning, rather dull afternoon, shower in the evening.

A very mild week, temperature equal to that usual in the first week of April. Barometer rising fast on the 21st.—G. J. SYMONS.

COVENT GARDEN MARKET.—FEBRUARY 22.

THE markets here have been tolerably firm during the past week, and former quotations fully maintained. Cornish Broccoli is now becoming plentiful and is a great acquisition. A considerable demand has been made among the waterside houses for ordinary Potatoes for shipment to France during the last fortnight; a few frame Ashleaved are to hand, to 1s. to 2s. per lb.

From observations taken near London during forty-three years, the average day temperature of the week is 49.1°, and its night temperature 32.3°. The greatest heat was 70°, on the 4th, 1860; and the lowest cold 14°, on the 3rd, 1862. The greatest fall of rain was 0.48 inch.

RAISING AND PLANTING-OUT SUCCESSFULLY EARLY PEAS.

OF all the important kitchen-garden plants none are in greater variety to perplex the cultivator, being but slightly different in their character, than early Peas. This is sufficiently exemplified in the numerous seed catalogues, almost every nurseryman advocating his own kinds, yet each of these, apparently to a great extent, only some formerly well-known variety slightly altered by local influences. However, it is to be hoped in time to come, for the benefit of the private gardener, that, as much as possible, the number of nominally new varieties may be restricted to the most trusty kinds.

A few days ago I planted out my first earlies. The kinds are Sutton's Ringleader and Dickson's First and Best. I adopted what I may call (at least it is so to me), a comparatively new method of raising early Peas. A little more than three weeks ago I had a lot of boxes prepared. These were about 2 feet long by about 1 foot broad, and 4 inches deep. I had placed on their bottoms three rows of nicely-prepared inverted turves, almost fresh, and fitting neatly to each other. On the top of the turf, in all the boxes, I sprinkled a slight coating of good soil. Then, all being ready, on the top of the rows of turf the lines of Peas were sown. This done, I had the seed covered with a couple of inches of good soil, and the sowing was complete. I had the boxes placed on the floor of a vinery on the move, and they remained there till the Peas had pushed fully an inch above ground, after which time they were removed to a cooler Peach house to harden off the young plants.

On a tempting fine day last week I wanted a number of boxes for other purposes, and not having too many I thought in such weather I could not do better than transplant some Peas to their quarters out of doors. Accordingly I at once prepared a place for planting, by well forking and levelling the ground, which had previously been prepared in the autumn as for most early crops. The situation selected was at the back of a south border, nearly at the base of a Peach wall. As soon as the ground was ready, I had a line stretched at a distance of 6 feet from the bottom of the wall, and by it I cut out a trench the same as for laying Box, only a little deeper, so as to receive some additional fresh loam at the time of planting. I next began to lift the Peas out of their boxes, for these had been just taken out of the Peach house, and with the assistance of a flattened curved piece of iron which I found at hand, I easily managed to remove the first row without injuring the roots. This was the only row that gave me any anxiety in taking it out, for the remaining two rows were lifted out without any difficulty with my hands. Thus, without the slightest injury to the roots, and in the most simple manner, all the Peas were transferred from the boxes to their new quarters. The pieces of turf when taken out were dense masses of loose, beautiful, white roots, and, put into the ground as they were, success may be expected.

One row having been put in as described, I had ready as many hand-lights as would reach to the end of the line, and on consideration I thought I could not do better than put in a second row a foot or so distant from the first one, so that I might, as much as possible, take advantage of the temporary glass. I also thought on the closeness of the plants, but they can easily be staked out. I therefore forked-up ground enough as before, and put in another row, as in the previous case, only a foot nearer the wall. Both rows having been planted, they received a gentle watering, and the hand-glasses were at once put over them. The tops of the lights have been taken off every day since planting, and I have noticed that the progress of the plants has been regular, so that, after all our severe weather, I look forward to have a nice lot of fine early Peas.

The above plan of treating early Peas, as far as the use of the turf is concerned, I have not seen anywhere tried before. However, the method is most excellent, and as the rearing of a good stock of fine early Peas is a matter of great importance to a large number of your readers, I have thought it worthy of notice.—Robert Mackellar.

FORCING PELARGONIUMS.

When successfully grown, I know of no plants that will repay their cultivator better than those belonging to this branch of the Pelargonium family. Their treatment is very simple, and easy to understand, involving little labour, and hardly any expense, but in its results affording much pleasure and profit. These Pelargoniums are more valuable, perhaps, to the gentleman's gardener and grower for sale than to the amateur; still the latter, if he has a heated glass structure, may, with a little care and attention, grow them successfully. From what I have seen of several gardens for some time past I do not consider the varieties referred to are so generally grown as their good qualities entitle them to be. I think they cannot be excelled by any other class of plants for furnishing a rich display in the conservatory throughout April and during part of May; I do not mean isolated specimens here and there, but a batch of two or three dozen well-grown, neatly-staked, and tastefully-arranged plants. Or, if they are required to furnish only cut flowers for sale, or for supplying a family in London (and this is what most gardeners are required to do at the present season), a gardener cannot find in any other plant a more generous and a less capricious friend.

The varieties which I have found most useful for the purpose are Alma and Crimson King among the dark-coloured kinds, the latter especially carrying some very large beautiful trusses excellent for cut flowers; Queen of February and Alba Multiflora among the light-coloured ones; Phyllis, too, another light variety, will force, but is not so well adapted for the purpose as those previously named.

The cuttings may be struck any time between February and the end of September; February and July being, perhaps, the best times for the purpose.

I shall suppose that the cuttings are struck in February.

In selecting them it will appear almost needless for me to say that the stiffer and dwarfer they are the better, and I would not mention this were it not that no man can grow a good plant from a drawn lanky cutting. The cuttings should be inserted singly in thumb-pots, in soil composed of loam and silver sand in equal proportions, and placed under hand-glasses in a brisk sweet heat.

When the cuttings are struck and beginning to grow, the centre should be pinched out in order to induce them to form shoots. When they have done so they should be shifted into pots a size larger, using the same compost, and be replaced in the same situation, shading and keeping them close to the glass for a week or ten days. They may then be removed to a pit having no more heat than that which can be husbanded from the sun, and the amount of which will be considerable by the time the plants arrive at this stage. Whilst they are here do not admit much air, and shut up early in the afternoon. When the shoots produced from the first stopping have developed three or four leaves the points should be again pinched out to induce the formation of more shoots, after which the plants must be shifted into pots a size larger, using some well-decomposed manure in the compost. Shade the plants, and keep them close until they overcome the effects of the potting. Afterwards, they must have an abundance of air by day and a little by night. A light shading with thin tiffany for about three hours in the middle of the day, during midsummer, will benefit them. Since their last stopping the plants will again have produced more shoots, which may be pinched back as before, and now for the last time. I may remark, with reference to stopping the plants, that to secure a good regular head of bloom it is absolutely necessary to stop each shoot at the same time, not, as is too often the practice, stopping a few to-day and a few more in the course of a week or two. All weak or ill placed shoots had better be removed whenever perceived.

The plants should be potted for the last time about the end of July or the beginning of August in a compost consisting of two parts turfy loam, one part leaf mould, and one part rotten cow dung, with a good sprinkling of silver sand. The pots must be efficiently drained, using the riddlings of turf to cover the crocks, and never giving the plants a large shift. Afford plenty of room at all times if possible. Attend carefully to their watering; they will require a liberal supply of water—often twice a-day—during the summer. Keep the plants close to the glass throughout their growing season, but not too close in winter, on account of the fluctuating temperature—extreme heat by day and extreme cold at night—which I believe to be the principal cause of "spot" on the leaves.

The plants should not be introduced into heat until it is certain that the flower buds are formed on each shoot—a fact which is easily ascertained by a practical hand, even before the buds can be seen, by noticing the plump appearance of the ends of the shoots. The plants should never be subjected to too high a temperature, and on no account should they be kept far from the glass. While developing their blossoms they will be benefited by frequent waterings with clear manure water. At this time they may be neatly staked with green stakes, and on the morning of a fine day taken to the conservatory, where they will amply compensate for all time and labour spent on them.

When the plants have done blooming, place them out of doors on an open space of ground, gradually withholding water from them in order to ripen their wood thoroughly. About the middle of July they should be cut back to two or three eyes on each shoot, and be placed in a close pit to be started, as is usual with Pelargoniums. When they have sufficiently broken, put them into the same sized pots; they should not be potted or stopped after this. Fumigate frequently to keep down aphis.

Treated thus, Pelargoniums of this class will flower well for four or five years. After securing a stock it is well to propagate a dozen or more as desired every year, in order that a corresponding number of worn-out older plants may be thrown away.—O. Thomas, *Drayton Manor Gardens.*

RUMEX OBTUSIFOLIA.

I am beginning to think that Rumex obtusifolia will become a very ornamental plant, and may be styled the "Poor-man's Caladium." I have had some very striking forms of variegation in this plant, and about half of them will come true from seeds. The variegation is from pure white to golden yellow, in irregular markings, and sometimes the two hues combined with their intermediate shades; and occasionally a pure white or yellow leaf is produced, and is very beautiful with its red or pink veins.

I have grown Rumex obtusifolia as a pot plant, and although only a Dock it would be difficult to find a handsomer plant of the character for a cool greenhouse during March, April, and the beginning of May, after which time it may be planted out, to be repotted in the autumn. If well managed, in the second year one may produce magnificent specimens fit to adorn any nobleman's garden. I expect to be sneered at for advocating the cultivation of such "rascally weeds" as Rumex obtusifolia.

Of R. acetosa and Acetosella there are numerous variegated sports, but none that I have seen are of sufficient constancy to warrant me in recommending their cultivation.—W. E., *Gardener, Cromwell House.*

THE CAMELLIA, AND ITS CULTURE.—No. 2.

I now proceed to speak of *General Culture.* A good base to work upon in the cultivation of any particular plant is furnished by ascertaining the precise conditions under which it exists in its native habitats. We are not bound to follow these conditions slavishly in all the details of practice, but whatever the modifications we introduce we should never lose sight of the natural life of the plant. No doubt the best way to deal with the Camellia is to plant it in a span-roofed house 30 or 40 feet high in the highest part. The top lights of the house should be moveable, and removed during May, June, July, and August, and a light shading be made to take their place during the day. If the lights cannot be removed, in spring and summer a light shading of tiffany should be run under the glass. Shading is essential during the flowering season and from the time the young leaves expand. The soil should be effectively drained when the beds are formed. A very slight heating-power will suffice, but we cannot altogether exclude this from our calculations.

But however desirable ground culture may be, the Camellia must remain a pot plant for the many. The chief points demanding attention under this head are—repotting, watering, and pruning.

Once a-year at least, in August, every plant should be turned out of its pot and thoroughly examined. If the soil has worked into the rubble at the base of the pot or tub in such manner as to impede the free egress of water, remove the old rubble, and substitute fresh. If any worms are seen pull them out. Examine the ball of earth closely to see that the water has in the past percolated every part of it. If it has not, pierce the ball in various parts with an iron pin in such a manner as not to injure the roots, and set it in a tub of water, leaving it there until thoroughly soaked through. Plants that require larger pots or tubs, of which we must judge by the quantity and condition of the roots, may be at once transferred to such. The new soil required to fill the outer circle of the larger pots should be pressed down firmly with the fingers or a stick, so that the outer circle of earth may be at once almost as solid as the inner circle.

Watering is a point of the very first importance. It is here that the dog is often starved, and, perhaps, as often surfeited. The ill name he has acquired is, I believe, in nine cases out of ten due to too much or too little water. A copious supply should be given during the flowering and growing seasons when real work is going on, but at other times great caution is needed. I am favourable to the practice of watering freely at long intervals as the plant becomes dry, rather than to the common practice of giving small doses at shorter intervals. The starved appearance, the yellow sickly leaves often met with, if not due to too poor a soil, are due to injudicious watering. Rain or pond water should be used in preference to any other, and water containing lime should be studiously avoided. The practised hand can tell when a plant wants water by rapping or lifting the pot, thus testing the condition of the soil by sound and weight; but by others, whether water is required or not may be pretty accurately judged of by the look of the plant, and by stirring the surface of the soil.

Either too much or too little water during the season of rest will cause the dropping of the flower-buds before expansion. These results, however, are not due to this cause alone, but to any fault of cultivation that induces debility. There are, too, some kinds which are naturally or constitutionally liable to this defect, and others the flowers of which expand with difficulty. The best advice I can give with regard to such is to have nothing to do with them, they are the surly dogs of the

pack, and there are plenty in the pack of equal beauty and more accommodating disposition.

Pruning is an important operation, and should be performed in spring just after the flowering season, but before the new growth commences. If the plants have been skilfully grown but little pruning is necessary, only just as much as will keep them in shape. It is not advisable to cut back into wood of more than one year's growth, as the dormant eyes on old wood do not readily push forth. They may, however, be stimulated to do so by the agency of ground heat; and under this head I would allude to and condemn the barbarous practice of cutting Camellia flowers with wood two years old adhering to the flowers for the sake of obtaining a long stalk. Scrubby, poverty-stricken, and misshapen plants are very apt to result from this practice.

It is well known that the Camellia as a pot plant grows slowly, and like most evergreens from temperate and cold climates it requires a lengthened period of rest. The first six months of the year are in this climate the natural period of flowering and growth; and during the second six months the plants should be kept in a state of comparative rest. During the season of growth we make the foliage and set the flowers; during the season of comparative rest we establish the quality of the flowers.

What gardeners term sporting is a characteristic of the Camellia. The Pæoniflora will often produce red and white flowers on the same plant. Press's Eclipse usually produces striped flowers, but occasionally a red or a creamy-white flower will appear. Many of the striped kinds will also produce at times self-coloured flowers.

When removing the plants from the open air in September, the flower-buds, if too numerous, should in part be removed.

The green fly occasionally attacks the Camellia, but is easily disposed of by tobacco smoke. The scale is a more troublesome though less common enemy. It may be removed by a brush. For the health as well as for the appearance of the plants they should be kept clean, and that useful domestic article known as soap is all that is required for the purpose. Syringing with soapsuds occasionally is an excellent plan, and if the suds pass to the roots it will benefit rather than injure them.

With regard to the best varieties of the Camellia opinions on this point will probably differ, according to whether the individual flower or the general decorative character of the plant is most valued. The Double White combines these qualities, but there are others which possess them singly. Many of the Anemone-flowered varieties are among the most valuable for decorative purposes, and they flower profusely and grow more rapidly, ultimately forming large umbrageous trees. The species known as reticulata is gorgeous as a conservatory plant, but the florist would likely pronounce the flowers loose and untidy in appearance. I shall, therefore, recommend a list of twenty-five varieties from each separate point of view.

As florists' flowers I select:—

Cup of Beauty	Jenny Lind
Vicomte de Nieulante	Storyii
Reine des Beautés	Mrs. Cope
Augustina Superba	Bealii
Princess Bacchiochi	Sarah Frost
Mrs. Abbey Wilder	Adriana
Saccoiana Nova	Rafia
Countess of Orkney	Ubertina
Souvenir d'Emile Defresne	M. D'Offoy
Alba plena	Dante
Fimbriata	Jubilee
Valtavaredo	Aulica
Imbricata	

As conservatory plants I should choose the following:—

Lavinia Maggi	Fimbriata
Marchioness of Exeter	Chandlerii
Comte Boutourlin	Imbricata
Countess of Derby	Elegans
Catherine Longhi	Conspicua
Lucrezia Gazzarrini	Donckelaeri
Queen Victoria	Reticulata
Prince Albert	Corallina
Duchesse d'Orléans	Formosa
Henri Favre	Picturata
Mathotiana	Eximia
Bonomiana	Monarch
Alba plena	

In conclusion permit me to reiterate the opinion, that the Camellia, far from deserving the ill name it has acquired, far from being a difficult subject to deal with, is one of the least expensive in its habits, and one of the most tractable in its nature to be met with in the whole range of flowering plants. But before venturing to deal with it, it is only reasonable that we should ascertain its nature and requirements. What can we expect if we persist in keeping the dog unduly shut up, or in feeding him on unsuitable or insufficient diet?—William Paul, *Paul's Nurseries, Waltham Cross.*

VINES' DEATH UNEXPLAINED—PERVERSITY OF PEARS—HEATED BORDER FOR EARLY VINERY.

"A Constant Reader's" Vines (see page 124), are planted outside and taken through the wall—has he looked to see if the rats have not barked them just where they enter the house? I had a young Vine or two served in that way last year; they did not push, but the others grew very well.

The Pear you named for me (Knight's Monarch) was grown against a south wall. I had 150 similar to the specimen sent, and I intend propagating the variety rather largely, as there are only a few late Pears which are really good here (Yorkshire). For instance, I cannot ripen well Beurré de Rance and Ne Plus Meuris, yet Knight's Monarch and Glou Morçeau are good. The vagaries of Pears are very strange. Out of about fifty varieties grown here there are not more than twelve really good. All my Pears and Apples are on walls, and so are the Plums. Can you give me a hint or two as to ripening the two Pears I have mentioned?—J. W. K.

[Were the stems outside the house sufficiently protected from the frost whilst the stems inside were being forced? We had several Vines once killed in this way, and we knew of a similar case near here this winter. There are many situations in which Beurré de Rance does not succeed well; we should, however, have thought that Ne Plus Meuris would have done well. It succeeds as an open standard in the London district. We can only suggest to you to expose your fruit well to the sun, and especially to allow all late Pears to hang as long as possible on the tree.—Eds.]

Was the dressing applied hot to "Constant Reader's" Vines, as sometimes men will heat the dressing to make it work better? It should never be applied hotter than it would become from being placed on a flue or on the pipes. Are the Vines more than one year old? as, if so, it would not be a case of unripened wood. I see nothing particularly objectionable in the dressing or in the boiling. I always boil my dressing, as it blends the materials so much better; but compounds, such as the Gishurst, are sometimes of uncertain strengths. The same remark applies to tobacco paper. I use homegrown tobacco stalks chopped fine and well boiled. For Gishurst compound I substitute soft soap, together with a little soot and lime, which mixture, if put on at a temperature of 50°, would never cause any mischief. I have applied it to the Vines in five houses, to Peach trees, Figs, &c., for several years without any ill effects. Was nothing more used in the dressing than the ingredients stated at page 124? as I have heard of nux-vomica, urine, and sugar of lead being used, and the mixture of these and other materials might produce an injurious chemical action.—F. P., *Gardener, Hillington.*

"Constant Reader" does not explain whether the dead Vines are alternately with the live ones in the house, or whether they are all at one end, nor does he say how the border is situated—a matter of much consequence in early forcing.

I started my first vinery on December 1st; it contains eight Vines, and five of them have made good, strong, short-jointed wood, shown plenty of bunches, and are now in full flower. Of the other three Vines which are situated at the cooler end of the house, the first, a Sweetwater, has made weak shoots, and has not shown a single bunch. The second is Trentham Black, and the third Black Hamburgh. The last two have not made nearly such good wood, and have not shown so many bunches, nor are the bunches so large. Besides, they are at least three weeks later than the other five Vines, owing to the coldness of the border; for the fireplace, which is underneath the house, goes as far under the border as the roots of the five Vines extend. This proves the benefit of having the border heated for early forcing; for not only the Vines are more forward, but the crop is better in quality and quantity in the part of the house where the border is heated. I am much in favour

of having constant heat in the border when Grapes are hanging late in the season, but the border, of course, must be dry and the temperature of the house cool, the atmosphere being also dry.

I have two Lady Downe's Vines in the second vinery, situated one at the end of the house where the fireplace of the first vinery is underneath, and the other about the middle of the house where no artificial heat reaches the border. The Grapes were ripened last July, but those on the Vine which is situated in the unheated part of the border have not kept nearly so well as the others, although the treatment was exactly the same in both cases. The Grapes on the Vine above the fireplace look as plump and as full of bloom as they did last August.

The cause of the death of "CONSTANT READER'S" Vines may be the lime contained in the dressing glueing up the buds, or the dressing being too strong (for he does not say how much water he used); or it may be starting the Vines so early with the border unheated and the canes weak, the rising sap being too weak to force the development of the buds.—W. JONES, *Bodlondeb, Bangor.*

GROUND LEVELLING AND PRACTICAL GARDEN PLOTTING.—No. 13.

DRAWING PLANS.

To draw and transfer *fig.* 36 to the ground, form the rectangle A B C D, also the diameter lines E F and G H. Draw lines 1 2, 15 16, 17 18, and 39 40, which form the inside rectangle. On the diameter line E F draw the two triangular beds. Draw lines *i k* and *m n*. On the diameter line G H draw the two squares at equal distances from centre o; draw the diagonal lines *a b*, *e d* on one side, and *e f*, *g h* on the other side; draw lines *r s*, *t u*, *v w*, *x y*, and corresponding lines on the other side. Between lines A D and B C draw lines 39 40, 37 38, &c.; between lines A B and C D draw lines 1 2, 3 4, &c.

To transfer the figure to the ground, the distance between points A and B is 55 feet. Insert a stake at each point. From point B to point C is 84 feet; insert a stake at point C. Line C D is equal to line A B; insert a stake at point D. Line D A is equal to line B C; lay a line from stake to stake. On each side of the stake at point A measure 5 feet (which is the width of the side walk), and insert pegs as at points 1 and 39. On each side of the stake at point B measure 5 feet, and insert pegs as at points 15 and 40. On each side of the stake at point C measure 5 feet, and insert pegs as at points 16 and 18. On each side of the stake at point D measure 5 feet, and insert pegs as at points 2 and 17. Lay lines from peg 1 to peg 2, and from peg 15 to 16, from 17 to 18, and from 39 to 40. Where the lines cross each other are the angles of the inside rectangle. Insert a stake at each point, as at points *r w*. On each side of the diameter line E F, on line 1 2, measure 5 feet, and insert a peg at each point, as at *l l*; from points *l l* measure 13 feet to line E F, and insert a peg as at point *z*. Find the corresponding triangle on line 15 16, insert a peg at each point, and lay lines from peg to peg. From the pegs at points *l l*, on the side lines of the triangle, measure 7 feet 3 inches; insert a peg at each point, as at points *c g*. Find the corresponding points *e b* on the corresponding triangle. From the peg at point *r*, on line *r w*, measure 3 feet, and insert a peg as at point *f*. Lay a line from peg *e* to peg *f* as shown. From the peg at point *w*, on line *w r*, measure 3 feet, and insert a peg as at point *h*. Lay a line from the peg at point *g* to the peg at point *h*; where these two lines cross each other is the centre of the square; insert a peg at that point. On each side of that peg, on lines *e f* and *g h*, measure 6 feet; insert a peg at each point, as in the small circles. Lay a line from peg to peg, and the square is lined. On each side of the diameter line E F—that is to say, from the stakes at points E F, measure 11 feet 6 inches, and insert pegs as at points *i n* and *m k*. Lay lines connecting pegs *i* and *k*, also pegs *m* and *n*. On each side of the diameter line E F measure 2 feet, and insert pegs as at points 27, 28, 29, and 30, and lay lines connecting them. On each side of the diagonal lines *e f* and *g h* measure 2 feet, and insert pegs as at points *r s*, *t u*, *v w*, and *x y*, and lay lines connecting them. Find the corresponding points on the other side, and lay the corresponding lines in the same manner. From the stake at point A, on line A D, measure 16 feet, and insert a peg as at point 37. From the stake at point B measure the same distance on line B C, and insert a peg as at point 38. From the stakes at points A and B measure 22 feet, and insert pegs as at points 35 and 36. From stakes A and B measure 26 feet, and insert pegs as at points 33 and 34. Again, from stakes A and B measure 32 feet, and insert pegs as at points 31 and 32. Find the corresponding points on the other side in the same manner. Lay lines connecting pegs 37 38, 35 36, 33 34, 31 32, and also corresponding lines on the other side. On each side of the diameter line G H—that is, on each side of the stakes at points G H, measure 2 feet, and insert pegs as at points 7 8 and 9 10. Again, on each side of the stakes at points G H measure 8 feet, and insert pegs as at points 3 4, 13 14. Lay connecting lines

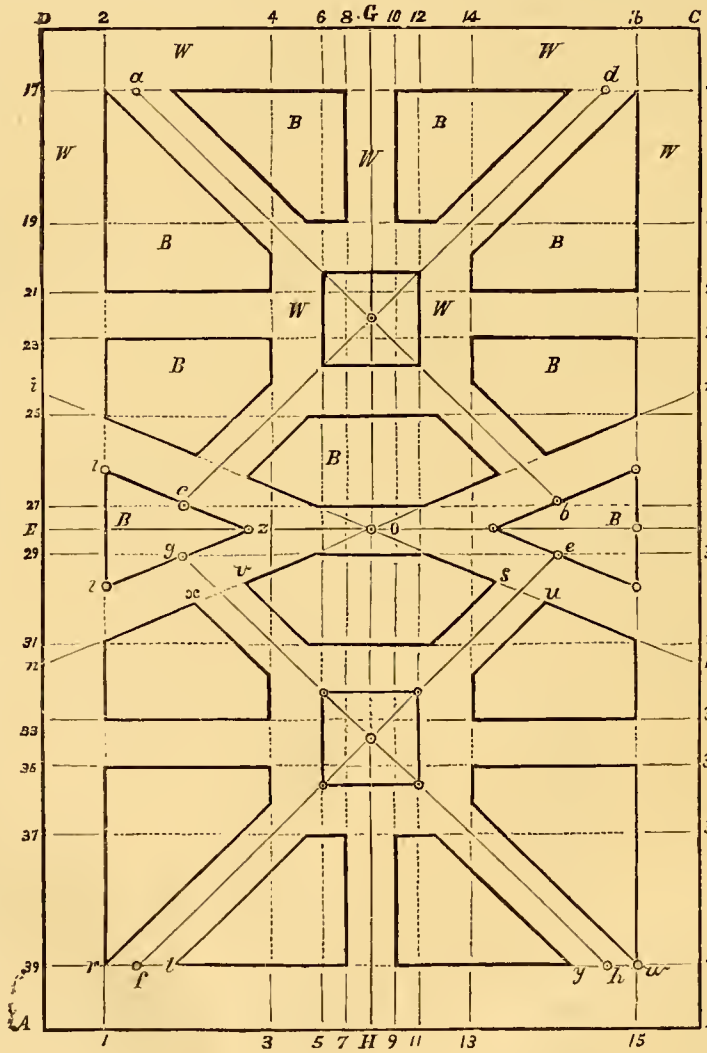

Fig. 36. Scale 16 feet to the inch.

between lines 7 8, 9 10, 3 4, 13 14, then all the lines are laid. The beds are intended to be edged with Box edging. The squares would answer well for vases. B, beds; w, walks.—M. O'Donnell, *Gardener to E. Leeming, Esq., Spring Grove, Richmond.*

FRENCH HORTICULTURISTS' RELIEF FUND.

A meeting was held yesterday, at the rooms of the Royal Horticultural Society, South Kensington, to consider the mode in which British horticulturists can best aid their suffering brethren in France, after the fearful hardships and devastation they have undergone through the war with Germany. Mr. G. F. Wilson, F.R.S., was in the chair, and there were present Mr. William Paul, Dr. Masters, Mr. Moore, Rev. H. H. Dombrain, Dr. Hogg, Mr. Standish, and Mr. Turner. Mr. Harry Veitch, Mr. Thomas Osborn, and Mr. Bull also took part in the movement, but were unable to be present at the meeting, The following resolutions were unanimously adopted:—

"1st, That it is desirable to make a subscription, and to solicit contributions in kind in aid of the French horticulturists who have been ruined or injured by the war.

"2nd, That a Committee be appointed to carry out this object, consisting of the gentlemen present at the meeting, with power to add to their number, and that the Rev. H. H. Dombrain be requested to act as Honorary Secretary."

We shall draw attention more at length next week to this desirable object, meanwhile directing our readers' notice to the fact, and strongly urging them to unite in making this laudable object a real success.

ROYAL HORTICULTURAL SOCIETY.

March 1st.

Fruit Committee.—G. F. Wilson, Esq., F.R.S. in the chair. Mr. James Batters, gardener to J. W. Fleming, Esq., of Chilworth Manor, Romsey, sent a very fine specimen of Queen Pine, weighing 4 lbs. The plant on which it was grown was twenty-two months old. It was much admired and received a special certificate. Mr. Douglas, gardener to F. Whitbourne, Esq., Loxford Hall, Ilford, sent a bunch of Mrs. Pince's Black Muscat, from a plant grafted on the Lady Downe's, and also a bunch of Lady Downe's from the stock plant. The fruit of Lady Downe's was of good colour and indifferent flavour, and Mrs. Pince was deficient in colour, but superior in flavour. Mr. Osman, gardener to H. Holland, Esq., Stanmore Hall, Middlesex, sent a dish of Loquat, the fruit of Eriobotrya japonica. The fruit was small but very highly ripened, and of excellent flavour, many of the members expressing an opinion that they were the best-flavoured examples of home-grown Loquat they had seen. A special certificate was awarded. M. Piccarillo, of Wigmore Street, sent cones of the thin-shelled Pinus Pinea, from Naples. The seeds of this variety have thin skin, and may be easily broken between the finger and thumb.

Mr. Cannell, of Woolwich, sent a model of a new boiler of his invention, and another was sent by Mr. G. Smith, gardener to Thomas Brassey, Esq., of Normanhurst Court, Battle, but the Committee decided that no opinion would be given upon any boiler a model, of which no practical experience had been obtained.

Prizes were offered for the best bunch of early Grapes, and for the best bunch of late Grapes. In the former class no first prize was awarded, the second went to Mr. Tribe, gardener to J. Sharpe, Esq., Waltham Cross, for Black Hamburgh. For late Grapes Mr. Sage, gardener to Earl Brownlow, Ashridge, was first with Alicante in very good condition, also showing Mrs. Pince a little shrivelled, not for competition. Mr. Bannerman, gardener to Lord Bagot, Blithfield, was second, with Lady Downe's, fine, also showing excellent bunches not for competition. Mr. Lynn, gardener to Lord Boston, was third with Alicante.

The first prize for the best dishes of Asparagus, Sea-kale, and Rhubarb went to Mr. Bray, gardener to E. Sandford, Esq., Nynehead Court, Wellington, for good samples of each. Mr. Miles, gardener to Lord Carrington, was second with fine Rhubarb, good Asparagus, but the Sea-kale coarse.

Floral Committee.—Mr. Denning, gardener to Lord Londesborough, sent a group of Orchids, among which were several fine specimens of Dendrobium nobile, one in particular being nearly 4 feet across, and a dense mass of blossom. Besides these there were Cattleya Trianæi, Cymbidium eburneum, Phalænopsis Schilleriana, Oncidium splendidum, conspicuous by its long spike of flowers, with a yellow lip 2 inches in diameter; O. leucochilum, and others; Odontoglossum cordatum in fine bloom, Pilumna fragrans, noticed in our report of the last Meeting, the pretty Dendrobium lasioglossum, D. capillipes with small orange yellow flowers, and Angræcum citratum. Mr. Denning also sent a very pretty unnamed Cheilanthes with finely-divided fronds.

From Mr. Williams came a varied and pretty group of Orchids, Palms, and other plants, in which were excellent specimens of Cypripedium villosum, Odontoglossums, Dendrochilum glumaceum, new hybrid berried Solanums, Iris reticulata, Cyclamens, Amaryllis, Camellias, the beautiful azure-flowered Tillandsia Lindeni, and other plants, together with a Trichopilia with white flowers, tinged with orange in the throat.

From the Society's garden came a fine plant of Dendrobium speciosum, and a new Lycaste, very free-flowering, and having drooping, dull fawn-coloured flowers, with an orange lip.

Messrs. Veitch, of Chelsea, sent a group containing fine specimens of Cypripedium villosum, Lycastes, Dendrochilum glumaceum, and other Orchids, together with Aucubas in berry, Pancratium fragrans, and Amaryllids; also Mormodes minax from Chiriqui, a rather showy new Orchid, purplish rose, with dark crimson spots and blotches, and the hybrid Lælia Pilcheri raised from L. Perinni and Cattleya crispa, the latter plant being shown in competition for Major Trevor Clarke's prize.

Messrs. Rollisson & Sons, of Tooting, sent a group in which were several Cypripediums of which C. villosum was very fine, Vandas, Phalænopsis Schilleriana, Dendrobium Wallichi, a variety of nobile, much finer than the latter in colour, Amaryllis, Palms, &c.

Mr. Lawrence, gardener to Bishop Sumner, Farnham Castle, sent Cattleya Trianæi Lawrenciana, a most splendid variety and beautifully flowered, also a fine specimen of Dendrobium Kingianum. Mr. Z. Stevens, gardener to the Duke of Sutherland, Trentham, exhibited several varieties of Azalea amœna. As shown, the plants had larger flowers and differed in the shades of colour, affording a pleasing variety. Mr. R. Dean, Ealing, sent Primula auriculæflora to show its merits as an early-flowering Primrose; and Mr. Knight, Floral Nursery, Hailsham, Princess Louise Victoria Hybrid Perpetual Rose, which is stated to be very free both in growth and flowering, and suitable as a climbing Rose.

Mr. Turner, Slough, exhibited a basket of Mr. Rutter Golden Tricolor Pelargonium, very fine. From Mr. Orchard, gardener to F. W. Harris, Esq., The Priory, Wimbledon, came seedling Violet Purple King, a cross between the Czar and the common Russian, having large, very sweet-scented flowers. Messrs. E. G. Henderson exhibited Eupatorium riparium, forming a plant 4 feet across, and bearing a profusion of charming heads of little button-like white flowers which would be extremely useful for bouquet-making. Mr. Ware, Hale Farm Nursery, Tottenham, exhibited two fine baskets of Sempervivum tabulæforme, the lively green saucers or platters which the plant resembles having a very good effect, also baskets of the charming little double Hepatica triloba rubra, pans of Scillas, a numerous and very beautiful collection of spring flowers, and a basket of variegated Ophiopogons. Mr. Moore, gardener to C. Leach, Esq., Clapham Park, sent a remarkably fine specimen of Dendrobium speciosum, and Mr. Pilcher, gardener to S. Rucker, Esq., Wandsworth, Masdevallia elephanticeps (?) with an extremely brilliant orange scarlet flower veined with deep scarlet. Odontoglossum Rossii, very fine, came from Messrs. Backhouse, of York, also Odontoglossum retusum-latro with rich orange blossoms. From Mr. Bull came Helcia sanguinolenta, and Odontoglossum Alexandræ with a fine spike.

Prizes were offered for the best six Camellias in pots, but there were no exhibitors. Messrs. Lane, however, sent a numerous collection, mostly small and well-bloomed plants. Prizes were likewise offered for cut blooms. The first prize went to Mr. Howard, gardener to J. Braud, Esq., Bedford Hill, Balham, who had fine examples of Fimbriata, Valtevaredo, Donckelaari, La Reine, Countess of Orkney, Chandleri elegans, Jubilee, Elegans, Alba plena, Aulica, and Imbricata. Mr. Baxter, gardener to C. Keiser, Esq., Broxbourne, was second, and Mr. A. Wilkie, Oak Lodge, Kensington, third. Mr. Trussler, gardener to D. J. Kay, Esq., Hoddesdon, also sent some good blooms. By far the finest exhibition, however, of Camellias was that from Mr. W. Paul, of Waltham Cross, who had no less than six large boxes of splendid cut blooms. Donckelaari, Alba plena, Corallina, and Imbricata each filled a box, and there were besides two stands containing a number of the best varieties.

Of shrubs in flower there was only one collection, coming from Mr. Wilkie, Oak Lodge, for which a second prize was awarded. It consisted of Rhododendrons, Azalea amœna, Lilac, &c.

Of Lily of the Valley the best six pots came from Mr. Howard, gardener to J. Braud, Esq., of Balham. These filled large pans, and formed a grand show. Mr. Searle, gardener to R. C. Steel, Esq., Hammersmith, was second, and Mr. Wilkie third.

First-class certificates were awarded to Mr. Denning, gardener to Lord Londesborough, for his new Fern, to Messrs. Backhouse for Odontoglossum retusum latro, to Mr. Turner for Tricolor Pelargonium Mr. Rutter, and to Mr. Pilcher for his Masdevallia.

Special certificates were awarded to Mr. Ware for his collection of plants; to Mr. Denning for his collection of Orchids, also for Dendrobium nobile and Oncidium splendidum; to Messrs. Veitch for a collection of plants; to Messrs. Lane for Camellias in pots; to Messrs. Rollisson for a group of plants, and for Cypripedium villosum; to Mr. Trussler for cut Camellias; to Mr. Moore for Dendrobium speciosum; to Mr. W. Paul for cut Camellias; to Mr. Williams for a miscellaneous group; to Mr. Lawrence for Dendrobium Kingianum and Cattleya Trianæi Lawrenciana; also for Dendrobium speciosum from the Society's garden.

General Meeting.—Major R. Trevor Clarke in the chair. After the election of thirty-one new Fellows the Chairman said Mr. Bateman would make some remarks on the losses of our French horticultural brethren.

Mr. Bateman said he would first make a few observations on the Orchids. The Masdevallias were eminently cool Orchids, as they grew on the limits of perpetual snow; they were also eminently mimetic Orchids, and one known to us only by drawings was M. elephanticeps, so named from its flowers bearing some resemblance to an elephant's head. The plant shown under that name was, however, probably only a variety of M. coccinea, and therefore M. elephanticeps was still a desideratum. The fine specimen of Odontoglossum Rossii from Messrs. Backhouse was next noticed, also the specimen of Oncidium retusum latro which was not only curious in the colour of its flowers, which was similar to that of Epidendrum vitellinum, but had also a curious trick of pushing, but never coming to the point of flowering. Notwithstanding every effort had been made in the Society's gardens it had obstinately refused to do so, but Messrs. Backhouse had succeeded; and no doubt in the future, when the bulbs gained strength, the spike would be of much greater length. The beautiful Cattleya from Bishop Somner's gardener, Angræcum citrinum, and some other Orchids having been briefly noticed, attention was next directed to a Berberis which a few days ago had formed a splendid golden corona in one of the houses at Kensington, and it was remarked that if it were desired to form it into a handsome plant, it was only necessary to keep its head cut off.

Mr. Bateman said he now begged to call attention to the serious losses French horticulturists had sustained in the war, and after drawing a picture of what would be the results to the nurserymen and market gardeners round London if a similar zone were trampled on by contending armies to that which has been the field of operations round Paris, said a Committee had been formed to aid French horticulturists. The Council, with the Fellows' permission, would, in addition, hand over any surplus seeds. The valuable Orchids at the Jardin des Plantes had been literally pulverised, but the Society would send any duplicates they possessed; Kew would assist; but still he urged those who had plants to spare to do the same. It would only be necessary to send to the Society the names of such plants in the first instance, and for himself he expressed his confidence that English horticulturists would contribute something handsome for their suffering brethren in France. In addition, a bazaar would be held in the gardens the week after Easter under the patronage of the Princess of Teck, the Duchess of Argyll, and others, and he invited contributions of articles, and especially of bonquets.

The Rev. M. J. Berkeley said, that after a careful examination, the Gastronema shown by Mr. Bull at the last meeting, appeared to be only a variety of G. sanguineum, or Cyrtanthus sanguineus, of the "Botanical Magazine," *t.* 5218. Mr. Ware's beautiful collection of spring flowers was next noticed, and especially the true Leucojum vernum which it contained, and in connection with it the early-flowering Crocus Imperatenius, to which the Chairman had drawn attention last year. A Wigandia in a diseased state, from Messrs. Henderson, Mr. Berkeley said, appeared to be affected with precisely the same disease as that which is so fatal to Verbenas, and the cause of this was ascribed to an unsatisfactory condition at the roots, for, on turning the Wigandia out of its pot, these were found to be in a bad state.

Mr. Berkeley then read a paper which had been communicated to the Agri-Horticultural Society of India last December, descriptive of a mode of rendering the Litchi stoneless by scooping out the pith and afterwards inarching, by which means, after each operation, the stone became less and less. Dr. Hogg had informed him this was by no means a new idea, for a similar method was mentioned in one of the old authors, but he (Mr. Berkeley) confessed himself incredulous of the success of the process, and on grounds which he stated.

The Chairman then made some remarks on the prizes which he had offered to the exhibitors gaining the greatest number of marks for subjects illustrative of the phenomena of hybridisation, and said, as soon as he could arrive at a definite conclusion as to the best manner in which they could be competed for, he would make the result known in the horticultural journals.

A Meeting was held on the same day as the above, to consider Mr. Marshall's new exhibition scheme (see pages 49 and 122). Mr. Marshall was in the chair, and after inviting suggestions, and there being a short discussion on the details, he proposed that the conditions should be printed and circulated among exhibitors, and opinions invited. Dr. Hogg said, as all seemed agreed on general principles and the only differences were on matters of detail, he would propose that a Committee be appointed to confer with the Council. He would not advise a large Committee. The Chairman invited him to name the members, to which Dr. Hogg demurred, but eventually the following were nominated—viz., Messrs. Baines, W. Paul, Williams, Moore, Turner, Fraser, Ward, and Dr. Hogg. It was then agreed that the proposed regulations should be printed and sent out, to be returned to the Committee previous to the next meeting, March 15th.

Additional Prizes.—G. W. Ricketts, Esq., offers first and second prizes of 20*s.* and 10*s.* respectively for two erect-flowered and two drooping-flowered Gloxinias, to be competed for on May 17th, also for Carnations.

LEAF-COLOURS IN AUTUMN.

A paper on the colours of autumnal foliage by Mr. H. C. Sorby, appears in the last number of the *Quarterly Journal of Science*. The chemical substances which give rise to the varying tints of autumn he divides into five classes or genera:—1. *Chlorophyll*, or the green colouring matter, which is very rarely found pure, even in fresh leaves. It is insoluble in water, but soluble in alcohol or bisulphide of carbon, and the spectrum has a well marked absorption band in the red. 2. *Xanthophyll*, or the yellow colouring matter; this is insoluble in water, but soluble in alcohol and bisulphide of carbon: the spectrum shows absorption at the blue end. It is found in various fruits, flowers, and roots. 3. *Erythrophyll*, or the red colouring matter. There is a strong absorption in the green part of the spectrum; the various kinds are usually soluble in water and dilute alcohol, but not in bisulphide of carbon. It is found in red flowers and leaves. 4. *Chrysophyll*, or the golden yellow colours, soluble in water and diluted alcohol, but insoluble in bisulphide of carbon. 5. *Phaiophyll*, or the group of various browns, soluble in water, but not in bisulphide of carbon. These are mostly due to the oxidation of chrysophyll. Unfaded green leaves are coloured mainly by chlorophyll, but the tint is very much modified by xanthophyll and by colours of the chrysophyll group. The various tints of autumnal foliage are produced by combinations of different members of the above groups; and Mr. Sorby gives the following scheme of their relative abundance:—During complete vitality and growth, we have different kinds of chlorophyll and chrysophyll producing more or less bright green; during low vitality and change, erythrophyll and xanthophyll make their appearance, producing more or less green-brown, red-scarlet, or bright orange-brown; while during death and decomposition phaiophyll and humus (brown-black) usurp their places, and gradually cause a uniform dull brown colour.—(*English Mechanic and World of Science.*)

THE FROSTS versus VEGETATION.

Mr. Ronson having asked for information (page 88) as to the effects on vegetation of the late severe weather, I am induced to offer a few particulars. For many miles in extent round here exposed culinary vegetables have in most cases suffered severely, and with me, such as Savoys, Kales, and Brussels Sprouts, are materially injured, infinitely more so than the same kinds were by the memorable severe weather of 1859-60. Broccolis and young Cabbage plants are completely destroyed; the latter, however, would doubtless have escaped injury but for an insufficient covering of snow, which, by the way, appears to have fallen more sparingly in South Warwickshire than in many parts, especially in the south of England.

Here I may remark that the importance of protecting frozen plants from the adverse influence of bright sunlight, has been forcibly exemplified by an instance that lately presented itself to my notice, in the shape of several hundreds of young Cauliflower plants pricked out under large hand-lights, and which, inadvertently, had been afforded no other protection from the alternating frosts and sudden thaws, in consequence of which every plant is *hors de combat;* whereas, had some slight covering been thrown over them, even after they had been considerably frozen, prior to the thaw, I believe the majority of them would have been saved, if I may argue from the result of the practice I fortunately adopted in protecting those I have under my own charge.

I hear sad accounts on all sides of injury to stored roots, such as Potatoes and Mangold Wurzel, and to Apples, where sufficient protective means were not, or could not be afforded. Evergreen shrubs and trees, however, appear to have sustained comparatively little injury in the grounds here, except in two or three cases; fully-exposed Laurustinus is materially injured. The lowest reading of Negretti's registering thermometer was 30° below freezing on the morning of the 31st of December, and I learn that 4° below zero was registered about five miles from here in a low-lying vale, where at all times during frosty weather a lower temperature is registered than with us.

The following are the readings of my thermometer from December 23rd to January 1st. It is fixed in an open part of the garden, and at 4 feet from the ground.

Dec. 23rd,	19°	below freezing point.	Dec. 28th,	7°	below freezing point.
,, 24th,	23°	,, ,,	,, 29th,	5°	,, ,,
,, 25th,	26°	,, ,,	,, 30th,	25°	,, ,,
,, 26th,	5°	,, ,,	,, 31st,	30°	,, ,,
,, 27th,	15°	,, ,,	Jan. 1st,	24°	,, ,,

STONE FRUIT FAR NORTH.

I was not aware till lately that you wished to have a report of the stone fruit grown here. My experience is so limited that my contribution, I am afraid, will compare very unfavourably with those of most of your correspondents; yet it may prove useful to north-country growers whom I am very anxious to encourage.

A south wall here, fronting one point east of south, and built in compartments of brick and of stone alternately, 9 feet

in height, and extending 48 yards in length, had been planted upwards of twenty years ago with six trees, allowing 8 yards for each tree. These were selected, I believe, from the Horticultural Society's "Fruit Catalogue," and were very successful. The Peaches intended to ripen in succession were Acton Scot, English Bellegarde, Noblesse, and Royal George. They gave an excellent succession from about the earliest season that it is possible to have Peaches on the open wall in this county until the latest period at which the Peach will be found to possess its usual high flavour. In October this ceases to be the case, and it is better to rely on Plums as a dessert stone fruit for that month than to endeavour to prolong the supply of Peaches. The Acton Scot bore well, and was of excellent quality, ripening about the 10th of August, but the tree is small, and the fruit medium-sized. We now expect that the Early York will supersede it. The Bellegarde, on the contrary, was a robust-growing, large tree, and bore most wonderful crops of from forty to sixty dozen, and one year produced eighty-five dozen. After some years of this heavy cropping, the trees were injured by a very severe frost, and we have now a succession of young trees taking their place. Amongst these the French Bellegarde, a beautiful dark-coloured fruit, promises to ripen well. The Noblesse bore and ripened well; nothing can exceed it in quality. We have now a smallish white Peach, sent as a Noblesse (which it is not), that is delicious. Royal George has long been the favourite Peach in this county, but it should be known that it is the latest variety that will succeed here, and that many sorts are at least one month earlier.

Our Nectarine was and is the Elruge. It is small, but bears very well, and ripens freely. Hardwicke Seedling is a larger and earlier fruit, but, excepting in a very fine season like last summer, when we had great heat, it is inferior. Violette Hâtive has not yet had time to prove itself.

Our Apricot was Moorpark, a delicious fruit. We have also grown Hemskerk, equally good, but smaller, and not so free a bearer. We have grown Breda, which here is quite inferior. I have seen some prodigious crops of Apricots in this neighbourhood: 125 dozen were gathered from a tree in the garden of the clergyman of this parish; but no variety that we have met with equals the Moorpark.

I have yet to state that some of our trees are on brick and some on stone walls, and some are planted so that one half of the tree is trained on brick and the other half on stone, but we have failed to detect either the blossom or the fruit being ever earlier on the brick wall than on the stone wall; that such should be considered to be the case appears, therefore, to be a delusion.

A good October Plum, to hang on the wall till November, is a desideratum. Coe's Golden Drop is apt to fall off when of the size of a small bean. Autumn Gage, a great bearer, is insipid. A white Quetsche is too early, and a dark one is inferior. Blue Impératrice promises well. Late Orleans has been considered our best October Plum. At Gordonstown, near here, the baronial residence of Sir W. Gordon Cumming, Bart., there is a large tree of this variety on a south wall, and for many years past it has not failed to produce an abundant crop of fine fruit lasting all the month of October.

Of Cherries, May Duke is a great and constant bearer; although early, it hangs long (under a net) on the tree. It succeeds much better on the wall than as a standard, but it bears and ripens freely on a north wall, as at Cullen House, the seat of the Earl of Seafield. We have some new earlier varieties, such as Belle d'Orléans, but we have not yet sufficient knowledge of them. The common White Heart Cherry of this country, of which there are large standard trees in almost all the old gardens, is a most delicious fruit. We have also a Bigarreau Cherry quite common and quite hardy. Next to these, or perhaps exceeding them in importance, is the Hungarian Gean, of which there is both a black and a red variety, bearing annually by thousands. An English gentleman, who was here two years since, was so charmed with them that he ordered ten trees from Mr. Grigor, Nurseryman, of Forres, who carefully propagates this variety. At Sea Park, the residence of Captain E. Dunbar Dunbar, where there are some large trees, the fruit annually is something wonderful to behold.

We protect all our stone fruit from frost, which, perhaps, is not very severe, owing to the proximity to the sea, by laying posts, with the butt end on the ground, about a yard from the wall, and the upper end resting against the top of the wall, They are put all along the wall, at about 4 feet apart, and a herring net, with meshes about an inch square, is put on double along the whole, and reaching from the top to within a yard of the ground. It is put on as soon as the blossom expands, and is left until the fruit are the size of large peas. Old herring nets are very abundant and cheap here.

Figs ripen well during August and September. A variety that has been for many years in this garden has been proved to be the same as the Brown Ischia, obtained for us from Chiswick by a Fellow of the Royal Horticultural Society. There is grown in the neighbourhood a larger sort, of a very dark colour, and equally good.

At Grant Lodge, near Elgin, the residence of the Countess of Seafield, I have seen a standard Mulberry tree completely laden with ripe fruit; in several gardens in this county such trees have been tried without success. When trained on the wall, continual application of the knife must be avoided. The shelter from the north wind, that rendered the trees at Grant Lodge so successful, has now been partly removed; but it is on record that a Mulberry, as a standard, where well sheltered from the north, with a good southern exposure, would be nothing new in our gardens.

Perhaps I should mention that we have Rivers's Early Favourite Plum and July Green Gage on a south wall, to succeed the Cherries and to precede the Peaches. We trust to standards for midseason Plums, as mentioned in a former notice.—JOHN MACCULLOCH, *The Gardens, Duffus, Elgin.*

SLOW COMBUSTION AND ECONOMY OF FUEL.

IT will interest many of your readers who have small houses under their own supervision, and to whom cheapness of fuel and a minimum amount of attendance are desirable, to know something about the firing burnt in this part of Wales. It amused me much when I saw it first. I allude to the Welsh "balls," as they are called. They are made of the small parts, or dust, of the anthracite coal of which "R. S." speaks so highly (see page 26). I can thoroughly endorse all he has said in its favour; and he is quite right in suggesting that the fireplace should contract from the top to the bottom, and the door should be different from that usually employed.

Now, the balls are far more economical than the fuel that "R. S." uses, and so slow is the combustion, that a fire can be made to keep in for from six to twenty-six hours by using different quantities of clay. This varies in colour, but that of a dun colour is the best, and it is found in low-lying ground at the depth of from 1 to 3 or 4 feet from the surface; this generally, but not always, being a black bog, 4 to 6 feet deep, and resting on a rough gravelly bottom. It is quite impervious to water, and scarcely any grit is to be found in it. It costs from 3*s.* to 4*s.* per good cartload, and can be kept in store for any length of time, if placed under cover. I should like to know if it can be obtained in England.

I will now suppose that the clay and coal are ready, and if under cover so much the better, for the materials can be made up in wet weather as is generally done here. The coal is sifted and put round to form a basin, precisely the same as a mason would do in making mortar. The clay is then placed in the middle, in the proportion of from one-eighth to a thirteenth part of the coal, according to the time the fuel is wanted to burn; the more clay, the more quickly it will burn. One-tenth is the proportion generally used here. The clay is chopped up fine, sufficient water is thrown on to make the heap of the consistency of mortar, and the whole is mixed together, well kneading it, by turning and treading, until the clay is thoroughly mixed with the culm. It is always best to use this fuel wet. When it is used in the house, as every person does, it is worked into balls and put on the fire, being about the size of a goose's egg, with the riddlings, if any, under them. When the fire is banked up for the night, a few balls are put under with a plaster 2 or 3 inches deep over them, and a hole is made in the top as a vent. We never hear of lighting a fire in this part—in fact, it would be as great a novelty to see a lucifer match in a cottage as a piece of roast beef on a Sunday.

There are other clays used when that which I have noticed cannot be had; one is a white clay similar to pipe clay, but not nearly so good, and three times as much of it are required. Those living near a river that deposits slimy mud on its sides, use that as a substitute. "A. B." (page 67) will find that these clays will be a great addition to his small coal and cinders, of which we have used many loads this winter, and if he could add a third part of small hard coal, the mixture would last much longer, and burn with greater certainty. The same ob-

jection applies to the anthracite coal and the balls as that which "A. B." makes to his small coal and cinders, for one must have wood or soft coal to "set the fire going;" if it is desirable to put on a fire in a cold morning, it will not be forced. The stoker must wait patiently after he has lighted the fire for it to burn up of its own accord, if poked it will not burn.]

As regards price, I think the fuel described will exhibit a favourable contrast to soft coal; we buy the coal at 6*s.* a-ton, and the clay and making cost 2*s.* per load. This is the extreme price here for making it. It is considered that one load of the "balls" will last as long as three loads of soft coal, the price of which is from 12*s.* to 14*s.* per ton. The small amount of ashes which come from the balls is a great advantage in a small stoke-hole; they partake of the character of burnt brick, and are an excellent material for applying to heavy land. There is no danger of sparks, and the annoyance of much smoke is avoided, for the cottages here have their chimneys of the shape of a small round hamper with the bottom out, rising about a foot above the thatch, and having a little mortar round it to keep it on; but I never heard of any disaster from fire.—J. T., *Maesgwynne, Carmarthenshire.*

SOLANUM CILIATUM.

THIS highly-ornamental species has been reintroduced by Messrs. Carter & Co., nurserymen and seedsmen, High Holborn, from Porto Rico. It was cultivated here fifty years since, and was portraited as long ago as 1813, by Dunal, in his "Histoire Naturelle des Solanum, &c."

It is either an annual, or has to be cultivated as if it were

Solanum ciliatum.

so, by being sown yearly. Its stem is herbaceous, from 12 to 18 inches high, having numerous yellow prickles; leaves subcordate, sinuately lobed, ciliated (hence its specific name) with prickles on their ribs; leaf-stalks short; flowers white, five-lobed; berries nearly spherical, more than an inch in diameter, orange-scarlet when ripe. These render it highly ornamental,

clustered among the dark green foliage, and especially fit it, being a dwarf plant, for table decoration.

THE WAR AND FRENCH GARDENING.

A week or two ago we gave an extract from a letter to Dr. Hogg, from Mr. Henry Vilmorin, of Paris, in which he mentioned his two brothers, Maurice and Phillipe, as being drafted into the army, and serving with the Mobiles. Those of our readers who know the family will be grieved to hear that Phillipe, the youngest of the Vilmorin family, and a fine noble lad of eighteen, has fallen a sacrifice for his country in the great struggle against the Germans. He was shot through the head at Commeré, near Le Mans, in January last, while courageously leading his company into action. M. Henry and M. Maurice Vilmorin have escaped unhurt.

The following description of the effects on the Jardin des Plantes of the bombardment of Paris is from "A Special Correspondent" of the *Times*:—

We drove through the usual gay and cheerful-looking throngs along the Quais to the Jardin, but here all was changed. The iron gates were shut, and the usually animated scene was desolate in the extreme. So we drove round to the house of M. Decaisne, whose celebrity as a botanist is too well known for any further comment to be necessary, and under his most kind and interesting guidance I visited a scene which was full of painful interest.

The gardens had apparently been a point of especial bombardment, and no fewer than eighty-three shells had fallen within their comparatively limited area. We went out to the glass houses to judge for ourselves of the effects. On the night of the 8th and 9th of January four shells fell into the glass houses and shattered the greater part of them to atoms. A heap of glass fragments lying hard by testified to the destruction, but the effect of the shells was actually to pulverise the glass, so that it fell almost like dust over the gardens. The consequence was that nearly the whole of this most rare and valuable collection was exposed to one of the coldest nights of the year, and whole families of plants were killed by the frost. Some of the pants suffered the most singular effects from the concussion; the fibres were stripped bare, and the bark peeled off in many instances. One house into which we went presented a most lamentable appearance of bare poles; scarcely a leaf was left. All the Orchids, all the Clusiaceæ, the Cyclantheæ, the Pandaneæ, were completely destroyed, either by the shells themselves or by the effects of the cold. The large Palm house was destroyed, and the tender tropical contents were exposed to that bitterly cold night; yet, singularly enough, although they have suffered severely, not one has yet died. Imagine Kew Gardens under a heavy fire, and Dr. Hooker standing disconsolate in the midst of them, his most cherished plants in ribands, and his glass houses a mass of powder, and we can form some idea of what M. Decaisne suffered during those fifteen nights, when shells came bursting under his window, sending splinters into his flower garden, and shaking his house to its foundations with every explosion. Feeling that, at all costs, he was bound to stick to his post, he passed the whole of his time actively engaged in covering up his plants in blankets, and straining every nerve to keep the cherished favourites of a lifetime from the ruthless missiles that were searching every nook and corner of the establishment. Two shells fell into the zoological gallery, one into the gallery of mineralogy, where it destroyed some beautiful pieces of palæontology. Three fell into the laboratories and museum, destroying a valuable collection of rare shells, which had just been classified. A long building had been turned into a hospital, and a shell had burst in it, blowing out every window, and crashing through the wooden wall; fortunately, all the beds were unprepared, the patients had not arrived, and no lives were lost. A sick man in an adjoining hospital was less fortunate, and was killed in his bed by a shell. The houses, historical as having been the residences of Cuvier and Buffon, did not escape, but fortunately, although several of the shells were found to be full of combustible materials, nothing was set on fire. All through the whole of the fortnight during which these gardens were subjected to this rain of shells, Messrs. Decaisne, Chevreuil, and Edwards remained at their post, unable to rest, and have since, at their own expense, repaired the damage done, trusting that whatever form of government France may choose it will not repudiate its debts of honour. The British public have nobly come forward to relieve the distress of the suffering population of Paris; I would now make an appeal to the comparatively small section of society whose glass houses may, perhaps, be supplied with plants which may replace those which have been destroyed. M. Decaisne is making out a list of his losses, a large proportion of which might possibly be supplied from Kew, while owners of private collections might also be glad to testify their sympathy and interest in the cause of science by contributing whatever they may be able to spare as soon as the amount and nature of the loss is ascertained. I feel no doubt that it will be enough to make the facts known, for the British public to respond with the same generosity which they have manifested in other instances.

The animals fared better than the plants—not only have none of them been eaten by the population of Paris, as the latter fondly suppose, but although several shells burst among them they have escaped uninjured. Of course, when food was so scarce for human beings, the monkeys and their companions were put upon short allowance. This fact, coupled with the extreme rigour of the season, increased the rate of mortality among them, and one elephant died, but was not eaten. The two elephants and the camel that were eaten belonged to the Jardin d'Acclimatation, and had been removed in the early stage of the siege from their ordinary home in the Bois de Bologne, for safety, to the Jardin des Plantes, where, however, it would appear, it was not to be found. The birds screamed and the animals cowered, as the shells came rushing overhead and bursting near them, as they do when some terrific storm frightens them; latterly they seemed to become used to it; fortunately the part of the garden which they inhabit is somewhat removed from the museums, at which the fire seemed more especially directed. The gates of this favourite resort were kept closed, because the price of firewood is so high and the scarcity of it such that the people are unable to resist the temptation of coming into the garden in search of fuel, and for the present it is found wise to shut them out; indeed, so much greater is the necessity for fuel than for food at present that the provision trains have been stopped by order of the Government to allow the coal trains to pass.

NOTES AND GLEANINGS.

At a meeting of the Committee of the Seed Trade, held at Anderton's Hotel, on February 22nd, Dr. Maxwell T. Masters in the chair, it was decided that a memorial should be forwarded to the Postmaster-General containing the following resolutions:—

"1. That for several years previous to October 1st, 1870, seedsmen had the privilege of sending by post small parcels of seeds and other articles under the then existing arrangements of the sample post, these parcels being generally so small in size as to be in much danger of being lost in the course of transit by rail, or other modes of public conveyance.

"2. That this privilege was a great boon both to the buyer and seller of seed, the seller being in the habit of sending to all parts of the United Kingdom and abroad many hundreds of such parcels annually. That to purchasers residing at remote distances from railway stations, or in places destitute of the ordinary means of transit, this privilege was one of the greatest importance, as parcels could be obtained through the post, safely, expeditiously, and cheaply, owing to the superior organisation of the Post Office mode of transit. That the enjoyment of this privilege tended in a great degree to develope an important branch of the industry of the kingdom—that of the production of seeds.

"3. That the postal arrangements now in operation interfere most injuriously with the transmission of seeds through the post; as purchasers residing in all parts of the United Kingdom, the Colonies, India, the United States of America, &c., are no longer able to receive such packages by post, unless paid for at letter rates, which are simply prohibitory, inasmuch as the cost of transit by this means would be equal to at least 20 or 25 per cent. of the average value of the seeds so forwarded. In this manner a considerable loss is entailed on the retail seed trade, as many of the persons engaged in selling seeds have gone to considerable expense to meet this particular requirement of the public—namely, that of obtaining certain seeds, delivered at a nominal rate, promptly and safely. That so expensive are the means of transit, otherwise than through the post, and so much danger is there of loss or delay, that were it not for the facilities offered by the Post Office, there is much reason to believe such purchases would not be made.

"4. That this Committee beg leave to advocate the establishment of a 'Parcels' Post,' by means of which there could be forwarded through the Post Office seeds, or other goods, in execution of an order. That such a parcels' post as that advocated by this Committee is in operation in other countries, and is found to be of great general convenience, and that the establishment of such a system in this country would prove a great boon, not only to the particular trade represented by the Committee and their customers, but also to other trades who have been great sufferers from the restrictions at present in force. That the transmission of parcels so sent might be subjected to certain restrictions as to weight and dimensions, and that the postal authorities might reserve to themselves the right to examine the contents of such parcels if deemed expedient to do so.

"5. That such a parcels' post is advocated by the Committee of the Seed Trade, not only because it would remove the numerous objections urged against the present postal restrictions, but also because it would tend to prevent any evasion of the regulations laid down by the Post Office authorities."

It is also resolved that a deputation from this Committee be appointed to wait on the Postmaster General, in conjunction with a deputation from the Manchester Trade Association.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Should the weather prove fine and the ground be found in a condition for sowing (when it crumbles beneath the foot it may be said to be so), the sowings of the principal crops may

be made. Make new plantations of *Artichokes*, and fill-up old ones. Sow Mazagan *Beans* in sheltered situations, and transplant those in the forcing house. *Beet* may now be sown. Sow *Red Cabbage* for autumn use. Sow a crop of *Carrots* out of doors, and thin-out those in frames. *Horseradish* should be planted, if there is not sufficient in already. Sow *Leeks* for the main crop. Sow *Lettuces*, and harden-off those in frames, to be planted out as soon as it can be done with safety. Stick early *Peas*, and sow several varieties for succession crops. Early *Potatoes* should be planted without delay. Sow *Parsnips* in drills a foot apart for the main crop. Sow a little *Savoy*, *Green Kale*, *Brussels Sprouts*, *Broccoli*, *Parsley*, and *Radishes*; and *Small Salads* must not be forgotten. Sow a few more rows of *Spinach* and Early Dutch *Turnips* in a warm situation.

FRUIT GARDEN.

Where circumstances have retarded the operations belonging to the orchard and fruit trees generally, no further time should be allowed to elapse. The application of fresh soil, pruning, nailing, and cleaning should each be completed with all reasonable dispatch. It is now time to look out for the opening blossom, and be ready on the first emergency to afford protection. Woollen netting, stout straw ropes stretched upon poles, or light frames covered with oiled calico, are amongst the available materials for the purpose. For the destruction of the Gooseberry caterpillar, now is a good time to rake away the earth from the stems of Gooseberry and Currant trees, and to dress them with soot and wood ashes, returning the earth as soon as that is performed. Prevention is better than cure, and this will save much hand-picking by-and-by.

FLOWER GARDEN.

The climate of England is, without doubt, the most favourable for the production of beautiful and verdant lawns, yet though we are assisted by climate in beautifying our flower gardens with a rich and verdant lawn, all efforts of ours will be comparatively futile unless proper attention be paid to the preparation of the ground. Of the two modes pursued in the formation of grass lawns, I am in favour of forming them by sowing a selection of Grasses, choosing those which are of a short and close growth. Sowing is done more expeditiously and economically than laying down turf, and in after years there will be no annoyances in the shape of Daisies, Dandelion, Sorrel, Hawkweed, &c. This is a good time for preparing ground for the purpose. Dig it carefully over, pick out all roots of perennial weeds, rake the surface, and bring it to the level required. Give it a good treading, and then roll it with a heavy roller to bring the ground to a regular and uniform consistency. Having done this, slightly stir the ground with the rake, sow the seed, and finally pass the roller over the surface. For a selection of Grasses suitable for this purpose, and the quantity necessary for an acre, I would recommend the following sorts for light soils:—Festuca tenuifolia, 2 pecks; Poa pratensis, 2 pecks; Anthoxanthum odoratum, 3 pecks; Lolium perenne tenue, 2 pecks; Agrostis stolonifera, 2 pecks; White Dutch Clover, 1 peck. For very strong heavy soil—Poa trivialis, 2 pecks; Festuca duriuscula, 2 pecks; F. ovina, 2 pecks; Anthoxanthum odoratum, 2 pecks; Cynosurus cristatus, 2 pecks; Alopecurus pratensis, 2 pecks; White Dutch Clover, 1 peck. When turf is in a bad state and difficult to mow in summer, let it be top-dressed with light soil, and some Clover seed sown upon it. Proceed with all operations that involve the necessity of wheeling or removing earth. Complete all planting, roll and sweep lawns, cleanse and turn gravel walks. Where it is necessary to eradicate weeds there is nothing like hand labour. In completing the arrangement of the flower garden, duplicate herbaceous plants may, perhaps, be found; these can be distributed about the pleasure grounds often with excellent effect. Prick-over flower beds, and get them in a wholesome state to receive the delicate plants intended for them. Prune Roses generally, and dress the beds with rotten dung. All trained trees and plants should receive attention. March winds are often destructive when the precaution of renewing old stakes and strings, rotted by the damp of winter, is neglected. Have soil and pots in readiness for potting Carnations, for which mix three parts of good turfy loam, two parts of well-rotted cow dung, and one part of rough sand and charcoal, and remove this compost into the potting-shed. The beds in which the choice varieties of Tulips are growing should be protected from heavy rains and frost; mats or thick canvas are proper materials for this purpose. The covering must be removed as the weather permits, otherwise the foliage becomes weakly and the stems drawn-up. By giving abundance of air the pillars gain sufficient strength to support the flowers without the assistance of sticks. Ranunculus seed, which ought to be sown now, should be carefully shaded from drenching rains. If covered with clean damp moss it prevents the surface from becoming dry and hastens the germination of the seed. Auricula seed should be sown in pans, making small ridges transversely on which the seed may be deposited. By watering between these the risk of the young plants damping-off is to a great extent avoided.

GREENHOUSE AND CONSERVATORY.

All the specimen plants in these houses should be carefully examined to see that the roots are in a proper state with regard to moisture, and the drainage clear. If you have the slightest suspicion that the interior of the ball of earth is in any case dry probe it immediately with a sharp-pointed quarter-inch iron rod, and give it a good soaking of water from the surface. To make assurance doubly sure, place the pot in a large saucer of water for twelve or twenty-four hours. After the severe weather we have lately experienced, and the extra fire heat used in consequence, many plants which will appear all right, are, nevertheless, very dry, and if they are not looked to in time the March winds will probably leave them dead or dying, when you little expect them to meet such a fate. Potting greenhouse plants should be commenced, not completed, at this time. Plants supplied with food in proportion to their progress thrive better than when over-potted. Ericas must be top-dressed or repotted. Tropæolums will require attention. Specimen plants of Pelargoniums require to have plenty of room, in order that the side branches may not touch each other. Push on Azaleas for decorative purposes in a warm, moist atmosphere; at this season few plants are more useful. Epacrises started now, so as to get their wood well ripened, may be had in full blossom in November. Of Amaryllids and Deutzia spectabilis, there should be a good supply; both may be had in bloom early in the season, and under good treatment they last long in beauty. Many Cinerarias will now be in full blossom, and in warm greenhouses will keep up a brilliant display for some time. Seed may be saved from some of the best kinds, which, when out of flower, may be set aside for that purpose.

STOVE AND FORCING PIT.

See that the plants in these structures receive no check. Increase the temperature gradually, a degree or two every week, and take care to shut up with 10° or 15° of sun heat on clear days. Keep a moist, growing atmosphere, and look well to the watering and potting of such plants as require it.

PITS AND FRAMES.

Maintain a kindly heat in the cutting frame; top cuttings which have taken root, and are beginning to grow. Divide and pot singly into 3-inch pots the old stools of herbaceous Lobelias. Fill several boxes with roots of Verbena venosa, and place them in heat.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

It has been a most favourable week for all out-door work. Some of our neighbours have been *sowing* their Onions and Carrots; our ground is not yet ready, and we have little desire to sow twice over. The ground might now soon be put in good order for sowing; indeed, as stated last week, it never was drier and sweeter at this season. Still, a press of other matters has prevented our getting the ground exactly to our mind, and we have a dread of sowing full crops of the above vegetables in cold soils even at the end of February. Half a dozen times in thirty years we have known Onions and Carrots fail from early sowing. The ground in these cases was in good condition. The seeds were good, as was proved by sowing earlier in heat, and later in the open air, but still the early-sown crop was a failure, and in some cases late sowing did not make up for it. If we were sure that such weather as we had up to the 25th were to continue, then we should say, Sow Onions, and even Carrots, and especially Parsnips; but if we have a sharp frost in the middle of March where would the tender chipped seedlings be? There are many things hardy enough for their seeds to stand a great amount of cold, and for the seedlings too to resist a great degree of cold when they are fairly above ground, that will at once give way just when the roots and stem emerge from the seed. It is rather singular, and we cannot account for it, though we have proved the fact over and over again, that seeds of hardy plants sown in spring, after being kept in comfortable bags or drawers all the winter, will be injured in spring by frost after germination has taken place, whilst seeds self-sown in autumn, or sown in autumn and re-

maining dormant all the winter, will not be at all influenced, or if so, only to a slight degree, by the spring frosts. In cold soils we have found it of little use to sow Mignonette out of doors until the middle or the end of April. Self-sown seeds will often stand the winter; and when we have several times sown at the end of October we have had fine lines of seedlings in May and June, which we would have looked for in vain if we had sown in February or March. The seeds which lie all the winter in the ground seem to be less influenced by changes of weather, and thus remain more dormant until the necessary heat as well as the other conditions for germination visit them; whilst seeds carefully saved in bags or drawers, when exposed to moisture and a little heat begin to germinate at once, and the little stems and rootlets are more liable to injury. We merely mention these facts, that our readers may not be in too great a hurry in this tempting weather to commit their seeds to the ground. The middle of March will do very well for Onions, the end of March and the beginning of April will do well for Carrots, and the middle of April will be time enough for Beet, Salsafy, Scorzonera, &c. Much earlier sowing will be attended with risk, especially if damp and frosty weather follow each other.

We have known a good many cases where seedsmen were blamed, and even changed, when they really supplied a first-rate article; but the seedlings were destroyed by frost just as they had chipped, and before they had a chance of appearing above ground. We are fully convinced that Onions and Carrots, when once the seed leaves are above ground, will stand an amount of frost which the seedlings will not do just after germination has commenced.

In *planting Potatoes*, &c., by doing the work in a sunny day time will be gained, not in regularly digging, but in scraping off and laying over the sets the fine, heated, dried, pulverised soil on the surface. We are supposing that the ground has been ridged or well dug previously.

Cabbages.—Our early crops are worse than we expected. We have taken up all the soundest out of the wreck, and planted them in rows together. We have had small plants, that survived in beds, taken up, potted separately, and put under glass with a little heat, and these, with plenty of air, are now so well rooted, that if next week be fine we shall turn them out into finely-pulverised soil, so that the disaster will be as little felt as possible. Smaller plants still we have planted over a slight hotbed of tree leaves in a rich rough compost of rotten dung and loam, and these, when established, we shall lift with little balls. We have also pricked off some seedlings just showing the first rough leaf, and which will soon be nice plants. We are always learning. We have been very successful of late years from plants sown in the middle and towards the end of July. We would be inclined to sow at that time for fine early Cabbages, but to sow also twice in September for later and surer returns. If our ground had been poorer, or if we had sown some six weeks later, we should have had more Cabbages to-day.

Part of the ground occupied with Cabbage stumps and some new Cabbages that have failed, we have had thrown out into beds and ridges; beds 4 feet in width for Celery, and ridges 4½ to 5 feet wine for *early Peas*, as Ringleader, Carter's and Chater's First, Sangster's No. 1, and that prolific Pea, Dickson's Early Favourite. The centre of the ridge was made into a hollow shallow trench before sowing to give the Peas every chance if we should have a dry summer, of which we have a dread, as our stores of water are as yet so low. The ground marked out for these ridges was first deeply dug and a little manure added, then the soil from the trench was thrown on them, the hollow made for the Peas well trodden, and the Peas scattered thinly in a broad trench after being red-leaded, then patted down and covered. We thus generally obtain heavy crops. We are obliged to make the most of little ground, and frequently we have Lettuces, Radishes, and early Potatoes in the trenches before the *Celery* is ready to plant out. For crisp, sweet Celery, decayed hotbed dung, with more tree leaves in it than dung, is best. We have grown Celery to enormous size, but now we are content with moderate, useful heads. When we used to send in huge blanched heads, there was little more went to table than from a nice moderate-sized plant. For our own use, except seeing that it was crisp, we would care nothing for Celery in its raw state, but it would be invaluable to us as a component of clear soup; and though anything but healthful when green, it is a great help to many, even in a medical point of view, when blanched. A small piece of ground as a bed, would enable the cottager to have a lot in little room. We generally grow it in beds, three and four rows across, and when the plants are tied there is no difficulty in the earthing-up. We have some nice red Celery now, but the Incomparable White has stood well. The great advantage of this is, that if you grow a plant 15 inches high you can send a foot of it blanched to table, and that is longer than generally goes there from the longest head, unless the proprietors of the establishment will insist on cutting up their own Celery. Very little earthing-up is required for this sort—a matter of great importance, but it must be sown early. The cottager, if he has no other means, ought to sow now in pots near his kitchen fire. It will repay the extra labour. To our taste no nut is so sweet as a piece of crisp well-blanched Celery.

FRUIT GARDEN.

We proceeded with pruning and nailing, and gave all the air possible to orchard houses to keep the trees back, so that the weather may be mild before the blossoms open. The later they are in opening the less will be the risk in unheated houses. Plants in pots require to be examined to see that they are not too dry. Forced Vines and Peaches will need to be regularly stopped, and the shoots thinned. Notwithstanding the absence of sun, the Peaches have set well—so well as to render a good deal of thinning necessary if the fruit stands well, but after such sunless weather, the fruit, though appearing all right at first, will frequently drop, the heart proving defective. However, there is no trace of this as yet, but it will be prudent not to thin too much until time prove them. The chief security in such sunless weather is to keep a rather low temperature in the house, so that the excitement given shall be in proportion to the light afforded. Strawberry plants are now showing well, coming strong and fine, and, therefore, looking for a pretty free watering with weak manure water.—R. F.

TRADE CATALOGUES RECEIVED.

J. Carter, Dunnett, & Beale, 237 and 238, High Holborn, London, W.C.—*Carter's Farmers' Calendar.*

Clark & Co., 42, Bishopsgate Street Without, London, E.C.—*Amateurs' Guide and List of Vegetable, Flower, and Agricultural Seeds.*

Sutton & Sons, Reading.—*Suttons' Farmers' Year Book and Select List of Grass and other Farm Seeds.*

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

Books (*H. T. H.*).—"Kitchen Gardening for the Many" can be had post free from our office for five postage stamps. It details Mushroom culture. "Fruit Gardening for the Many" details Filbert culture; it can be had in the same way for five postage stamps. (*J. W.*).—We do not recognise such a book as you describe.

Cuttings (*E. M. M.*).—Some nurserymen and florists occasionally advertise them, but we cannot tell where you can now apply.

Heating a Boiler by Gas (*P. H. B.*).—No one could foretell the cost, even if the seasons were always alike and you had told the price of gas, which you have not. We do not think gas heating suitable to your extent of buildings.

Select Hollyhocks (*J. W. B.*).—The following are good and cheap:—Fred. Chater, Gem of Yellows Improved, Alexander Shearer, Black Knight, Chairman, Lady Middleton, Rev. E. Hawke, Mrs. F. McKenzie, Purple Prince, Quadroon, Queen of the Whites, Stanstead Rival, Queen of the Buffs, Illuminator, Mrs. Chater, Willingham Defiance, In Memoriam, and Lilac Model.

Planting (*C. A. Dunn.*)—Any trees and shrubs in pots might be planted out now, and so may evergreen shrubs in pots; but fruit trees, Roses, and other deciduous trees and shrubs not in pots had better not be removed until September or October, as soon as the leaves begin to fall.

Geranium Leaves Spotted (*J. S.*).—The leaves have the appearance common to those grown in a rich soil, and kept in a close but cold moist atmosphere. There is no insect on the leaves. We think if you give the plants more air, and only water to keep the foliage from flagging, with a position near the glass, and a temperature of 45° or 50°, they will recover in a short time.

Nemophila insignis and N. maculata in Pots (*A. B.*).—Your plants being from seed sown last September, they will, though they are now showing flower, be suitable for spring gardening, but we should strongly urge the necessity of withdrawing the lights of the frame whenever the weather is mild, employing them only in very severe weather; indeed, harden them off at once so as to plant out by the middle of March. They will not flower much before May, unless you keep them under glass.

Centaurea candidissima Propagation (——).—We presume your old plants have side shoots 2 or 3 inches long; if not, place them in a gentle heat of 50° to 55° until they have; then take them off close to the stem, pare the base smooth with a sharp knife, and insert them singly in small pots in sandy soil. Making a hole in the centre of each pot, drop in a little silver sand, then introduce the cutting, fill-in round it with silver sand, and make firm. Place the pots in a bottom heat of 70° to 75°, and keep close, moist, and shaded from sun. Be careful to keep the

soil no more than moist, otherwise the cuttings will damp off. They will make good plants by the end of May.

SOLANUM CAPSICASTRUM SOWING (*M. G.*).—Sow early in March in sandy turfy loam with a little leaf soil, just covering the seed, and place in a hotbed of 70°. When the plants come up keep them near the glass, and when the rough leaves appear pot the seedlings singly in small pots, and continue them in the hotbed, shading from bright sun until established; then harden them off and remove them to a light airy position in a greenhouse. Shift as the plants fill the pots with roots, stopping the side shoots at the third joint, but training the leader erect, and so as to form pyramids. Seedlings do not flower freely, consequently the berries during the first two seasons are not numerous.

ABUTILON STRIATUM SOWING (*Idem*).—Sow the seeds in sandy loam with a little leaf soil added, and place them in a hotbed, potting-off the seedlings when a few inches high, and when they are established remove them to a greenhouse, repotting as they fill their pots with roots. The plants will not flower this season, therefore in winter keep them rather dry, prune in spring, and repot when the fresh shoots are 2 or 3 inches long.

PYRUS (CYDONIA) JAPONICA SOWING (*Idem*).—Prepare a pot or pan with good drainage, and fill it to within half an inch of the rim with light turfy loam. Scatter the seed evenly on the surface, and cover it with fine soil. The pan may be placed in a gentle hotbed until the seedlings appear, and should then be removed to a cold frame. When the seedlings have two or three rough leaves, plant them out in a sheltered situation in lines 6 inches apart, and 3 inches asunder in the rows, shading from bright sun for a few days, and watering as required.

GERANIUMS AND CALCEOLARIAS FOR BEDDING (*Idem*).—*Golden Variegated:* Mrs. Pollock, Golden Chain, Lady Cullum, Cloth of Gold, Luna, and Sunray. *Silver Variegated:* Bijou, Brilliant, Queen of Queens, Lady Plymouth, and May Queen. *Zonal:* Beauté de Suresnes (deep rose), Rose Rendatler, Crimson Perfection, Blazer, Little Excellent, Waltham Seedling, Sunlight, Christine Nosegay, Le Grand, Excellent, Queen of Nosegays, and White Perfection. *Calceolarias:* Aurea floribunda, Amplexicaulis, Prince of Orange, Prince of Orange (Yellow), Beauty of Montreal, Gem, and Sparkler.

BORDER SOWING WITH ANNUALS (*A. C.*).—As you do not wish to go to any great expense we would sow in lines, and you will have room for twelve at 1 foot apart. Next the edge we would have—1, Lobelia speciosa, which will need to be sown in heat, and its growth encouraged, planting out in May; 2, Sweet Alyssum; 3, Golden Feather Pyrethrum, 4, Saponaria calabrica; 5, Mignonette; 6, Nasturtium, Tom Thumb Scarlet; 7, Large-flowering Ten-week Stock, violet; 8, Tagetes signata pumila; 9, Perilla nankinensis; 10, White Branching Larkspur; 11, Blue Branching Larkspur; 12, Prince's Feather.

PLANT PROPAGATION (*J. L.*).—1, Erica carnea is increased by parting the tufts, though the long shoots root freely if they are detached and in the ground, leaving about 3 inches of the growing points outside. 2, Winter Aconite is raised from seed sown as soon as ripe in any sandy soil, and by offsets as soon as the flowering is past. 3, Melilotus leucantha is raised from seed sown in sandy soil in gentle heat. You give the popular name of 2, its proper name is Eranthis hyemalis; 3, is popularly known as Melilot; 1 is known as Early-flowering Heath.

PLANTING VINES (*Idem*).—You will not gain anything by now planting young Vines where you intend your new vinery to be. No doubt the Vines would become well-established as regards roots, but the canes would not ripen, so that you would need to cut down and have a year's growth before you could hope for fruit.

GRAFTING A VINE—FUMIGATING PEACH TREES IN FLOWER (*A. B. C.*).—Foster's White Seedling will succeed admirably on the Royal Muscadine. The only effect is in its accelerating the ripening. Fumigation with tobacco will not injure the flowers of Peach or Nectarine trees, care being taken to deliver the smoke cool, and have the flowers dry. Calceolarias will flower quite as well if they are planted out where they are to flower, at the close of March or early in April, protection being given them in frosty weather.

VINES ON THE BACK WALL OF A GREENHOUSE (*Poplar*).—Your Vine ought to have been pruned in December. We would now remove any loose bark, and wash it with a solution of soft soap at the rate of 2 ozs. to the gallon, adding enough flowers of sulphur to bring it to the consistency of paint. You will require but a small quantity for one Vine; therefore, only use a proportionate part of the soft soap. Apply the mixture with a brush. Bring down the cane and train it horizontally at 1 foot from the ground, and it will break at almost every eye; rub off all except those shoots which are, as nearly as possible, 18 inches apart, and train these upright to produce shoots for fruiting another year. If your cane is planted in the centre of the house, train a shoot from the base for covering the part for which you will not this year have a shoot, and in the autumn you can train it horizontally, and shoots from it will in due time come for covering the other parts of the wall. Do not prune the Vine now, but as soon as it grows rub away the eyes of the lengths not wanted, and when there are leaves cut away any superfluous length. A bottom heat of 70° is suitable for Geranium cuttings.

PLANTING GOLDEN FEATHER PYRETHRUM (*Ignoramus*).—For an edging the plants should be 9 inches apart. We have double rows and plant quincunx fashion, allowing 6 inches between the rows, but the plants are 9 inches apart. Keep the flowers closely picked off.

HYACINTHS IN GLASSES (*Idem*).—The flowering being past, your best plan will be to plant them out in a sheltered situation out of doors. They may recover so as to bloom in the out-door borders, where they are very pretty in spring. The bulbs are of no use for growing in water again.

ANNUALS FOR EARLY SOWING (*Idem*).—Sweet Alyssum, Bartonia aurea, Candytuft, crimson or purple, lilac, and white; Clarkia pulchella and alba; C. elegans rosea and pulcherrima; Collinsia bartsiæfolia, C. bicolor, Erysimum Perofskianum, Eschscholtzia californica, E. crocea, Gilia tricolor, G. tricolor alba, Branching Larkspur, Leptosiphon densiflorus and its variety albus, Limnanthes Douglasii, Lupinus nanus, Lupinus vellow, rose, white, and blue; Mignonette, Nemophila insignis, N. maculata; Saponaria calabrica and its variety alba, Silene pendula and its varieties alba and ruberrima, Venus's Looking-glass, Virginian Stock red and white, Viscaria oculata, and Whitlavia grandiflora.

ORCHARD-HOUSE CLEANING (*A Subscriber*).—You must not syringe the timber with a solution of soft soap, as it would fall on the glass and spoil it. We would give the house a thorough cleaning, and leave the trees alone now that the buds must be swelling. The solution of soft soap and quassia chips may injure the bloom buds. The whole of the timber we would wash with hot soft-soap solution, and thoroughly clean the glass with pure water.

RE-TUBBING TREE FERN (*H. M.*).—Now is the best time. In doing so we would not reduce the ball, but merely loosen the sides, and transfer it entire to a larger tub. Be careful to make the drainage good.

INDIFFERENT HORSERADISH (*A Three-years Subscriber*).—Judging by the piece you enclosed we should say your ground is poor and too heavy for this root. Could you not lighten the soil by trenching it 2 feet deep, and adding sand or ashes? We would make a fresh plantation every year, and use the roots after two years' growth; they will then be three times the thickness of that enclosed, quite white, and tender. Plant full-sized crowns 18 inches deep. That you sent is very woody and of bad colour. You do quite right in striving to please, but some cooks cannot be pleased, and such as a rule receive far too much encouragement from those who ought to discountenance the grumbling of one servant against another.

AMARYLLIS GIGANTEA.—"*W. C.*" four years ago purchased a bulb of Amaryllis gigantea weighing more than a pound, and it annually makes plenty of growth. It is started and grown in heat, but will not flower. Those having succeeded in flowering it will oblige by stating particulars of treatment.

HEADING PLUM TREES (*Constant Reader*).—The leading shoot, or the central one, should be cut back to within 1 foot of the base of last year's growth to induce the production of shoots for covering the wall, but the terminal shoots of the principal side branches should not be shortened but left at their full length, unless more shoots are required for covering the wall, when it may be necessary to shorten their leaders to obtain shoots where such are required.

ORANGE TREES CASTING THEIR LEAVES AND FLOWERS (*J. L.*).—There can be no two opinions as to the cause of this; it arises from a bad state of the roots, no doubt occasioned by the damp atmosphere and want of warmth. You seem to think the roots are all right, but we question that. We think the soil is too wet, and the roots not in a healthy state. Remove the surface soil down to the roots, and top-dress with light, rich, turfy loam, adding a third of fresh horse droppings. The drainage of the border in which the pots are sunk we apprehend is not good. A top-dressing of cocoa-nut refuse will serve as well as the loam, and some think better. Do not overwater at the root, and maintain a temperature of 50° at night. The Ferns can have no prejudicial effect, only the rockwork may, if it communicates with the border, render the latter too wet, and be in effect the evil you complain of. See that the drainage of the pots is good. Why not make a good border and plant the trees out? They do far better than in pots or tubs.

LAPAGERIA ALBA FROM SEED (*T. H.*).—The seeds should be sown now in a compost of fibrous peat, covering them with fine soil, and after watering gently, place the pots in a hotbed of from 70° to 75°. Keep the soil moist, and when the plants appear admit air moderately, and place them near the glass. Continue them in the hotbed, or transfer them to another if the heat in the first declines, and when the plants are a few inches high remove them to a cool stove or warm greenhouse. We think it best to sow the seeds singly in 3-inch pots, and transfer the plants to larger when the roots show at the sides. The most suitable compost is turfy brown peat, torn in pieces with the hand and used rather rough, though for young plants it should be smaller than for established plants. The drainage should be extra good, as the watering must be copious; indeed, it is not possible to overwater if the drainage is efficient.

REMOVING SHRUBS (*A. G.*).—You would be acting illegally in removing the trees and shrubs without the consent of the landlord. In taking up the shrubs be careful to preserve all the small roots you can, and if you could lift them with a ball of soil all the better, but any soil falling away freely should be removed, as it would be lost in transit, and increase the weight without doing any corresponding good. Take up the deciduous trees and fruit trees carefully, preserving all the fibres practicable. There is no better material in which to wrap-up the roots than dry straw, the roots being placed together and then covered with straw to keep them from the air. The top will need to be secured carefully with bast matting and string to guard against breakage. In addition to covering the roots with straw, they should be wrapped in mats if they are to be transmitted by rail, so as to make neat packages. You may safely move them at this time of year. Could you not remove them in a cart? You would in that case save much of the trouble of packing, but it is necessary in any case to cover the roots with mats, so as to protect them from the drying influences of sun and wind.

PLANTS FOR THE BACK WALL OF A GREENHOUSE (*Amateur*).—The back wall of a greenhouse is not in general a good place for plants. A good yellow-flowering plant is Acacia oleifolia elegans, which has been in flower with us since last September. Habrothamnus elegans has deep rose-coloured flowers, and is fine. There is no scarlet-flowering plant that would suit except Camellias, and Monarch, bright scarlet, large, with fine foliage, would suit. The best blue is Heliotrope—Voltaireanum being good, and Monsieur Hamaitre fine for winter-flowering. Twelve select greenhouse plants are Acacia armata, Chorozema cordatum splendens, Correa Brilliant, Cytisus racemosus, Nerium rubrum plenum, Pimelea spectabilis rosea, Polygala Dalmaisiana, Rhododendron jasminiflorum, Vallota purpurea, Libonia floribunda, Eriostemon linearifolium, and Eutaxia floribunda.

TACSONIA VAN-VOLXEMI GOING OFF (*T. H. T.*).—We should attribute the falling of the leaves to the cold, and it may be that the plant is at rest. We should ascertain the state of the wood, and if that is all right we would prune early in March, and encourage growth by keeping rather close and warm for a short time. If the wood is dried-up the plant is dead, and you will have no alternative but to replant. Our plant in a cool greenhouse is now growing freely, and has been growing all the winter, showing flower at every joint. It is planted out in the border in turfy loam with a little leaf soil. It has not had any water since October, except that which drained from the pots on the stage over the border.

MALE AUCUBAS (*Idem*).—Both male and female plants are produced from the berries. Plants raised from berries of one plant are partly male plants and the rest female plants. The males are of more slender growth than the females, and the leaves have a tendency to droop, but there is no certain mode of distinguishing the male from the female plants until

they flower, or form buds for flowering. The flowers of the female may be impregnated, though the male flowers appear much earlier, by collecting the pollen when dry on clean white paper, and keeping it in a dry cool place until the female plants flower, then dusting the pollen over them.

Wild Decorative Plants (*A Welshman*).—We cannot advise you, not knowing the flora of your locality. Why not judge for yourself and employ any ornamental plant that you observe? We once saw a table well decorated with the leaves and flowers of Herb Robert, Geranium Robertianum.

Age of Vines for Vinery Planting (*Mary*).—One-year-old are to be preferred if well grown.

Planting a Vinery (*R. Rayne*).—You may plant Vines in the vinery, to be taken longitudinally along the stove house, and to be brought back into the vinery to winter. Three would do, and these we would make two Muscats and one Hamburgh. The Vines in the vinery ought to answer very well. If you wish them to have the whole house in summer and to have plants chiefly in winter, then have eight Vines. If you want flowering plants in summer, then five or six Vines would be enough. For succession we would have—Dutch Sweetwater, Royal Muscadine, Black Hamburgh, Black Muscat of Alexandria, Black Prince, Trentham Black, Bowood Muscat, Lady Downe's, and Trebbiano.

Paradise Apple and Quince Stock Propagation (*C. T. H.*).—Paradise stocks are increased by layers at this season, it being necessary to have good "stools" to begin with, and these it will take you some time to establish. Layers made now will be fit to detach in November, and may be planted in lines 2 feet apart, and 6 inches from each other in the lines. In two years they will be fit to graft. Cuttings may also be put in now firmly in sandy loam, taking them off about 8 inches in length, with a small portion of old wood, and removing all the eyes except the three uppermost; all, except that part with the eyes is to be placed in the soil. Water, if necessary, and cover with a hand-glass, removing it in July. Shade from bright sun as required. Your best plan would be to purchase a few stocks. Quince stocks are raised from cuttings, taking the young wood, and cutting it into lengths of 10 inches. The treatment is the same as for Apple cuttings. They may also be raised from layers and by suckers. The cuttings will be rooted by autumn, and may then be planted out the same as the Paradise stocks. It would serve you better to purchase rather than to propagate.

Name of Fruit (*D. B. T*).—Golden Noble.

POULTRY, BEE, AND PIGEON CHRONICLE.

RESULTS OF POULTRY-KEEPING.

I will state my experience as a beginner.

I have three Brahma pullets and one cockerel, hatched in May last year. The first pullet commenced to lay on November 24th, the second on December 14th, and the third on December 17th. During this period, the pullet that first commenced to lay has been broody for a fortnight. The total quantity of eggs they have laid up to the present date (February 11th) is 155, a result, I think you will admit, much more favourable than that referred to by your correspondent, Mr. R. Wilson. My feeding has been barleymeal in the morning, and Indian corn or barley in the evening, at a cost for each fowl of about 1½*d.* per week.—E.

JUDGES CLAIMING BIRDS AT POULTRY SHOWS.

Some of my friends have directed my attention to a letter inserted in the Journal of last week, from Mr. James Watts, of Hazlewell Hall, reflecting on the claiming of pens of poultry by one of the Judges at the late Wolverhampton Poultry Show, prior to its being opened to the public. Permit me, as one of the Judges, to state I was not inculpated in this transaction in any way, for so far from my ever making the office of poultry-judge a matter of pecuniary gain, at all the Wolverhampton Shows, under the management of various poultry committees, I have at once willingly complied with their desire that I should arbitrate for them, but of my own free will it has always been a gratuitous duty, and though comparatively a trifling amount, my unavoidable cab and railway expenses have also been defrayed out of my own pocket. The simple fact is this, that I never bought or sold a single bird at any one of these Shows.—Edward Hewitt.

THE WAVERLEY POULTRY AND PIGEON SHOW.

The Waverley Poultry Association's fifth Exhibition was held at Melrose on the 22nd and 23rd ult. Of Poultry and Pigeons the entries were larger than at any previous show, but there were very few specimens of small birds. While the birds were under the care of the Committee they were well attended to, and were seldom left by Mr. Park, who acted in the place of Mr. Turnbull, the Honorary Secretary, who was ill.

Of Silver-Grey and Dark *Dorkings* there were some good birds, though the entries in these classes were not numerous. In the *Spanish* class Mr. Waugh, of Melrose, showed a grand cockerel, and there were several other very good male birds, but not one good hen. The winning *Cochins* were both Buffs. The White and Partridge varieties were too small to compete successfully. In *Brahmas* the winners were of the Dark variety. The second-prize birds were larger than the first, but the latter were most exquisite in colour and lacing, the former being also rather rusty in hue. There was but one class of *Game*, which we consider a mistake, but there were some good birds, although several pens seemed to be sadly overshown. The winners were Black Reds, the first-prize birds being in splendid bloom, and perfect in shape and handling, though in the latter respect they were scarcely equal to the second-prize birds, although these were not up to them in appearance. There were not many entries in the *Hamburgh* classes, but the winners were as good as could be desired, the Golden-pencilled pullets being excellent in marking. Among the Golden-spangled Hamburghs one of the hens was found to be trimmed, and was immediately disqualified. The first-prize pen in this class was an even pair of birds, well shown. The Silver-pencilled were good, but the first-prize Silver-spangled were a grand pair. In the Variety class a valuable pair of Crêve-Cœurs were first, Silver Polands second, and Black Hamburghs third, but a nice pair of Black Polands were too late for competition.

All the classes of *Bantams* were well filled, but many pens were somewhat out of condition. Of the Black Red Game Bantams, one pen, which otherwise would most assuredly have won, were discovered to be very neatly shortened on the fourth and fifth pinion feathers of each wing, and were disqualified at once. The first-prize pair in that class were excellent. There was scarcely one really good Black Red cockerel with the proper quota of broad feathers in his tail, some showing a vacancy at the top, and others at the bottom, and whether by accident or design we know not; but if the latter, we would advise the exhibitors of that variety never to take feathers out of a Game fowl's tail, as nothing tends more to destroy the symmetry and compactness of appearance so desirable in the breed. In the next class a very pretty pair of Piles was first, good Brown Reds being second. Of the Bantam single cocks, the first-prize bird was a grand Black Red cockerel, and the second a very good Duckwing. Several handsome pens of Bantams were too late for competition.

There were not many entries of *Ducks*. The Aylesbury were very good in quality, but the Rouens even better. The first prize in the Variety class was taken by Mandarins, and the second by Black East Indian. There were some good birds in the cottagers' class. The *Turkeys* and *Geese* were of the highest merit, both as regards size and plumage.

In the *Pigeon* classes the Fantails were good in style and carriage. The first-prize Pouters were Blue-pied, and the second White. The latter were of great length, but not in showing condition. The first-prize Nuns were a grand pair, and in nice order, but an excellent pair was left out, being evidently out of health. The winning Jacobins were both Reds; the first-prize birds were very good in hood and chain. In English Owls only the first-prize pair and the second-prize cock were of the true type, most of the others being too straight in beak. The first-prize Tumblers were Almonds, good in all points, and the second Kites. The winners of the first prize in the Variety class were a very handsome pair of German Letz. The second-prize went to a nice pair of Black Austrian Pouters, the third to good Black Trumpeters, and the fourth to a very neat pair of White African Owls.

Dorkings.—*Silver-Grey*.—1, D. Hardie, Hawick. 2, J. Cunningham, Jarbreoch, Kirkcudbright. *hc*, Earl of Haddington; T. Raines, Stirling. *c*, F. L. Roy, Nenthorn. *Dark*.—1, D. Gellatly, Meigle. 2, T. Raines. *hc*, D. Hardie.

Spanish.—1, D. Waugh, Melrose Mill. 2, Sanderson & Oliver, Morpeth. *hc*, D. Waugh; E. Fearon, Whitehaven; R. Douglas, Langholm; A. Walker, Kilmarnock.

Cochin-China.—1, — Jacob. 2, E. Fearon. *hc*, J. W. Will, Errol; E. Fearon; J. Radoch, Rusley, Glasgow. *c*, J. H. Dawes, Moseley Hall.

Brahma Pootra.—1, W. Brownlie, Kirkcaldy. 2, L. Stewart, Edinburgh. *hc*, T. Raines. *c*, T. Simpson, Melrose; L. Stewart.

Game.—1, J. Brough, Carlisle. 2, D. Hardie. *hc*, J. W. Will (3); J. Henderson, Musselburgh. *c*, A. Dewar, Linton, Cluny; D. Harley, Edinburgh; J. Logan, East Shiels, Carnwsth.

Hamburghs.—*Golden-pencilled*.—1, W. R. Park, Melrose. 2, A. Pratt, Kirkcaldy. *hc*, J. W. Will; W. R. Park. *Golden-spangled*.—1, R. Dickson, Selkirk. 2, H. Pickles, jun., Earby. *hc*, J. W. Will. *Silver-pencilled*.—1, H. Pickles, jun. 2, R. Blackburn, Choppington, Morpeth. *Silver-spangled*.—1, J. W. Will. 2, Ashton & Booth, Mottram. *hc*, W. R. Park. *c*, F. L. Roy; Miss Donn.

Any other Variety.—1, W. R. Park (Crève-Cœur). 2, H. Bowker, Keighley (Silver Polands). 3, J. P. Fawcet, Whitby (Black Hamburghs). *vhc*, E. Fearon, Whitehaven (Polish). *hc*, W. Bearpark, Ainderby Steeple (Silver Polands); R. Parsons, Bedlington (Polands); W. R. Park (Crève-Cœur). *c*, J. Logan (Hoodans).

Game Bantams.—*Black Red*.—1, G. Hall, Kendal. 2, J. W. Will. *hc*, D. Hardie; T. Raines; W. Brownlie. *Any other Variety*.—1, Bellingham & Gill (Pile). 2, J. W. Will (Brown Red). *hc*, J. Archibald, Earlston (Brown Red); W. Brownlie (Duckwing); D. Harley (Brown Red).

Bantams (Any other Variety).—1, Mrs. Hardie (Black). 2, Miss R. C. Frew (Black). *hc*, J. Archibald (Japanese); S. & R. Ashton, Mottram, Manchester; A. Johnston, Bathgate. *Cock*.—1, G. Todd, Monkwearmouth, Sunderland (Black Red). 2, T. C. & E. Newbitt. *hc*, G. Miles, Newstead (Black); J. Ferry, Cowpen, Morpeth (Brown Red). *c*, W. Goddard, Earlston (Black Red); J. Gibson, Melrose (Japanese); W. Scott, Jedburgh.

Ducks.—*Aylesbury*.—1, J. Scott, Newhall. 2, J. W. Will. *c*, J. Grieve, Broomhill, Melrose. *Rouen*.—1 and 2, D. Hardie. *Any other Variety*.—1, S. & R. Ashton.

Selling Class.—1, W. R. Park. 2, J. Scott, Newhall. *hc*, E. Fearon.

Cottagers' Class.—1, J. Beattie, Rink, Selkirk (Brahmas). 2, Mrs. Waugh, Melrose (Spanish). *hc*, Sanderson & Oliver, Morpeth (Spanish); W. Linton, Selkirk (Crève-Cœur). *c*, R. Renton, Dingleton (Spanish); T. Brown, Melrose; E. Strickling, Brackenthwaite, Whitehaven.

Turkeys.—1, Earl of Haddington. 2, A. Johnstone, Bathgate. *c*, J. Logan (Cambridge.)

Geese.—1, D. Hardie (Toulouse). 2 and *hc*, J. Logan (Toulouse).

PIGEONS.

Fantails.—1, A. Crosbie, Melrose. 2, M. Crosbie, Gattonside. *hc*, Miss B. P. Frew.

Pouters.—1, M'Gill Skinner, Edinburgh. 2, F. M'Crae, Aberdeen. *hc*, J. Coutts, Ellieston, St. Boswells; G. B. Phillips, Ayr.

Nuns.—1, R. Paterson, Melrose. 2, W. Bearpark. *hc*, J. Turnbull, Melrose.

Jacobins.—1, W. E. Easton. 2, F. Moore, Burnley. *hc*, R. Paterson; J. G. Spence. *c*, J. Campbell.

TURBITS.—1, R. Paterson. 2, A. Crosbie. *hc*, R. Paterson; W. E. Easton. *c*, F. L. Roy.

OWLS (English).—1, R. Paterson. 2, W. Goddard. *hc*, J. Coutts; J. G. Spence.

TUMBLERS.—1, F. Moore. 2, F. M'Crae. *hc*, W. Goddard; A. Johnston.

ANY OTHER VARIETY.—1, A. Crosbie (Letz). 2, W. Goddard (Austrian Ponters). 3, T. Rule (Trumpeters). 4, W. Goddard (White Owls). *hc*, W. Taylor, Durham; T. Rule (Trumpeters); W. Bearpark; W. Goddard (White Owls); A. Johnstone, Bathgate (Porcelains).

SELLING CLASS.—1, W. Goddard (Ice Pigeons). 2, J. Campbell (Carriers). *hc*, G. B Phillips (Magpies). *c*, A. Hutton, Carolside (Jacobins); J. Turnbull (Fantails).

CAGE BIRDS.

CANARIES.—*Yellow Don.*—1, G. Laidlaw, Galashiels. 2, J. Muirhead, Galashiels. *hc*, R. Laurie, Melrose. *Buff Don.*—1, G. Laidlaw. 2, W. Bogie, Melrose. *hc*, A. Polson, Galashiels. *Yellow Flecked.*—1, A Polson. *Buff Flecked.*—1, E. Hunter, Tillicoultry. 2, A. Polson. *Common.*—1, C. Mann, Newstead. 2, J. Gibson, Melrose.

CAGE BIRD (Canaries and Goldfinches excepted).—1, J. Turnhull. 2, Miss E. Waugh.

GOLDFINCHES.—1 and 2, R. Paterson. *hc*, W. Bogie.

The Judge was Mr. E. Hatton, Pudsey, Leeds.

FARM BREEDING AND MANAGEMENT OF POULTRY.

WE have been requested to state that in the report of the discussion which followed the reading of a paper on this subject by the Rev. G. A. Brooke, at a recent meeting of the Midland Farmers' Club, the remarks of Mr. T. B. Wright were given in an abridged form, and consequently in one or two instances did not fully represent the views of the speaker. We therefore readily comply with a request, and give the remarks of so good an authority from another and more complete report.

Mr. WRIGHT said that the first point which occurred to his mind was that it was impossible to lay down any strict rule as to the breed which should be recommended to be universally kept. Difference in climate, soil, and convenience had to be considered. Some poultry required great ranges, while others did well in confined spaces. Such varieties as Game or Hamburghs would be worthless if kept in a confined space. With regard to keeping poultry generally, one of the great difficulties was that two runs or yards were requisite—one for the old and the other for young birds. Without such accommodation it was almost impossible to keep them profitably or satisfactorily. Many of their agricultural friends had out-barns, where the chickens could be sent when old enough to leave the hen, where they could be fed at little cost, and thrived admirably. Where they had not two walks it was well for friends to join—the one to keep the old breeding stock and the other the young birds. With regard to which was the best variety of fowls for farmers' use, in anything like a favourable situation the Dorkings were to be recommended. In the number of eggs they laid they were not equal to either the Hamburghs or the Brahmas; but for the table there was not a breed equal to them. They were very fair foragers, getting their own living as far as possible, and very well repaid the food they ate. They came to market great weights at a tolerably early age—a couple of pullets, for instance, weighing from 10 to 11 lbs. at eight months old. In damp localities Dorkings would not do, as they were in such situations liable to roup; the latter tendency arising generally not so much from the nature of the fowl, and their liability to that disease, as from want of care on the part of persons who keep them. If Dorkings were not so much crowded together, they would be very much less affected by roup. With regard to roosts and the care of poultry, he had been very fortunate in hatching a considerable number of chickens every year. He had only a small roosting place, and till he could kill them off they were very crowded. Notwithstanding that, however, he had rarely any disease among them; and when disease did appear it was always introduced by fresh birds from another district. What he did was to have the roosting places swept out every morning, and the floor sprinkled with sawdust and MacDougall's disinfecting powder; and he recommended every poultry—and he might say stock—keeper to use the latter, as a preventive of disease. As to feeding, a variety of food was to some extent necessary; and he thought that some errors were committed in regard to feeding. For his own part he never used Indian corn, as it made the poultry fat and gross, and the eggs had not the right flavour. The food he had used for a long time had been a small but good sample of English wheat, and barley; the latter, when steeped, being an excellent thing for bringing fowls into high condition. He soaked the grain one day, putting it afterwards into an iron dish in the oven or near the fire until it was sprouted a little. With regard to large kinds of poultry, which wanted plenty of bone-forming material, bran, sharps, and meal were very useful; but the best thing he had found for his young Dorkings, in addition to other food, was a good sample of small white peas, which were not expensive keep. In regard to other varieties of fowls, for an amateur who wanted beautiful objects about his place, there was nothing superior to the Silver-spangled Hamburghs. They were constant layers and non-sitters; while, for the table, he was quite certain that no poultry could surpass a couple of young cockerels of this variety, hatched in April, and killed about November or December, weighing about 10 lbs. or 11 lbs. The pencilled were very beautiful, but more delicate; but one of the most useful of all fowls, especially to the inhabitants of our towns or villages, was the old-fashioned Copper Mass, Moonies, Golden Pheasants, or "Red Caps," as they were called in some localities, which, he was sorry to say, had been deteriorating for a number of years. If a large supply of eggs of good size was wanted, no variety was better. If some of their friends could induce the Cochins to abandon their propensity to sit, they would be doing good service. He had had them sitting for months on a heap of stones. They were not, as a rule, very good for the table. A young Cochin cockerel, about five or six months old, would have consumed a wonderful quantity of food, but after that age they were not good, and the pullets were never so. Brahmas might find favour as an amateur's fowl. They were handsome, and laid well; but they were not table fowl, he should say. Malays were a valuable variety, and he was surprised they had not received more attention. They were not handsome in appearance, but, as a table fowl, most excellent. He thought crosses of all kinds in poultry were decided mistakes. They had been told that the best of all crosses was that between the Brahma and the Dorking. For two years he took the opportunity of testing this point fully with some of the best strains, and when the birds were killed they were not so heavy by 3 or 4 lbs. the couple as some pure Dorkings which were hatched at the same time. The crosses had broad, deceptive, flat backs, but no breasts. He thought this was the case with regard to all crosses. Unless there were plenty of rain in the spring, and the worms appeared, poultry never throve so well; and the last three seasons had been against them in that respect. A great mistake was made in the manner of killing poultry. Much of the poultry which came to town was killed, plucked, and sent to market at once. They should be fasted nearly a day before killing, and hung a week or a fortnight according to the state of the weather, when the meat would be much better and much more nutritious.

RABBIT SHOWS—THE UNITED KINGDOM RABBIT CLUB.

MUCH has been said, little has been done, respecting Rabbit shows of recent date. Suggestion follows suggestion very rapidly, but no suggestion is adopted as the final basis upon which a modified exhibition is to be founded. The proposed Society is a very good idea, and I hope the project will be responded to by all the fanciers of London, who seek their standing in the provincial towns, owing to their not having a suitable exhibition of their own. I do not doubt such a society will be successful in attaining its object, but it is necessary that an enterprising gentleman should take the matter in hand. I beg to propose that a committee be formed; that a selection of one or two gentlemen be made from each town where the idea is entertained, so that all may be fairly represented; that the preliminary steps be taken by the projectors; and that they shall nominate the gentlemen (if willing) who are to officiate as the committee. I believe no place could be more suitable for the show than the Crystal Palace, but of course this is an after consideration.

Respecting the Colchester Show, I perceive by the list that a sum of £12 is given for prizes, and I am indeed surprised only £3 should go to the Lops, whereas the remaining £9 is to be equally divided among the three variety classes.

"Is the Rabbit fancy on the decline?" is a question often put, and readily answered. The statistics of the numbers of entries, not including the varieties and lengths of the respective Rabbits exhibited, would not fail to convince the most prejudiced gentleman that the "fancy is steadily increasing every year." Although I see no decline in the fancy, yet I perceive no desire for improvement, such as is exhibited by poultry and other fanciers. I know no reason why the Rabbit fanciers should not count among their numbers gentlemen with enterprise equal to those who wield the affairs of other societies.—A. G. C., *London*.

I AM greatly delighted that my suggestion, as to the formation of a United Kingdom Rabbit Club, has met with the approval of all respectable fanciers; and in taking the first step, I have invited all the Rabbit fanciers in York to meet me on Tuesday, March 7th, in the saloon of the Lecture Hall, when I shall be prepared to explain my scheme; also, to receive suggestions, consider rules, and to enrol members. I shall be glad if those fanciers in the United Kingdom who cannot attend this preliminary meeting, and who are favourable to the cause, would at once write to me and state their opinions as to how such a club shall be worked, the rules, &c. I hope to receive hundreds of letters from all parts, and be warmly supported by the fanciers. I have a strong conviction that if this Club be founded upon a simple and sound basis, it will add greatly to the numbers and to the respectability of the fancy.—M. MILLINGTON, *York*.

BEES NEAR WOLVERHAMPTON.

IT is an old observation that dry summers are productive of honey and wet ones productive of swarms, and this no doubt as a rule still holds good. Our summers of late (probably owing in part to the extensive draining and felling of timber

which has been carried out), seem to have become much drier than they were formerly; and in this district the excessive drought of such seasons as 1868 and 1870 exercises a very prejudicial influence upon the ensuing summer by destroying the crop of Dutch clover, which is the principal source from which the bees collect their honey harvest. In 1868 I obtained a large quantity of first-rate honey, but the drought of the summer almost entirely destroyed the clover for the following season, so that although the weather in 1869 proved very propitious, the bees were for a great part of the summer almost entirely idle, and only collected sufficient honey to supply their daily requirements. The result was that they refused to enter the supers, and all the combs in the stock hives and nadirs were completely filled with brood; and although the bees had ample accommodation they exhibited an almost uncontrollable tendency to swarm. For several weeks I overhauled my storified hives every seven days, and was obliged to excise royal cells time after time to prevent the issue of swarms. At last a copious honeydew made its appearance upon the beech trees, on which the bees were eagerly occupied from morning till night. They at once entered the hitherto-neglected supers, and speedily laid up a considerable store of honey of a very dark inferior quality, bearing a strong resemblance in colour and consistency to common treacle.

In 1870 the bees at once took to their supers, within a few hours of the time when they were put on, and I obtained a tolerable harvest of beautiful clover honey; but I fear the drought which prematurely closed last season has destroyed the clover roots for this summer, and so impaired the prospects of the coming season. In localities where the permanent turf abounds in white clover, the prospect is much more favourable. In 1869, when our clover, sown to succeed barley, was entirely ruined, in Cheshire and other favoured localities the bees were able to amass large stores of excellent honey, whilst we were entirely dependent upon honeydew.—J. E. B.

REGICIDE BEES.

You printed an article at page 131, describing the death of a queen in consequence of strange bees getting into a hive. It said "a few." How can they cause the death? Do they turn regicides, or does their presence make the others become so? —J. L.

[The intrusion of strange bees into a hive will frequently induce an attack upon the queen. It is, however, a debateable point whether the assault is made by the strangers alone, or if the regicidal spirit be also communicated to the native bees.]

NEW BOOK.

The Honey Bee. *By* Dr. Bevan. Third Edition. Edited by W. A. Munn, &c. London: Van Voorst.

We have now lying before us a new volume, which professes to be a third edition of Dr. Bevan's work on the honey bee, "revised, enlarged, and illustrated by William Augustus Munn, F.R.H.S., &c." Knowing that the book originally published by Dr. Bevan has long been held in high estimation by the public as a valuable text book and exponent of English bee-knowledge up to the time at which it was written, though now far behind the wants of the age, we were prepared to welcome an edition that would give by way of notes or addenda a full account of the progress of apiarian science. But so far as information respecting recent discoveries and acknowledged improvements in apiculture is concerned, the book now submitted to us for review is utterly worthless. Its so-called revision has resulted in rendering it a medium for advertising and puffing the merits of a cranky and unsightly-looking hive, which was patented by Major Munn in France a few years ago.

This hive was never either admired or approved of by us, and though it may serve for some experimental purposes, a glance at its cramped combs and ridiculously small frames will be enough to convince anyone who knows aught of the habits and necessities of bees, that it is quite unsuitable for the purpose of abundant honey-gathering. Major Munn would like it to be believed that he was the inventor of the frame system; he even takes credit for it, and asserts that whether frames be square, oval, or triangular, they are all founded on the bar frame which he introduced in 1834, and that the square is that which all bee-hive makers have copied from 1844. This is mere assertion, and without any adequate foundation. It is preposterous to say that Munn's hive has been copied either in Europe or America, or that its invention gave any impetus to scientific bee-keeping. We are only informed now of his attempt to use square frames; his triangular ones were merely devised to enable him to lift his combs into observation-frames, and so far was he from considering them truly moveable, that he at first fixed them to the hive by means of hinges. Dzierzon was the first to develope the use of moveable-comb hives into a system, and that he did not copy Munn is evident from the fact that he has consistently stuck to simple bars, and neither uses nor recommends frames of any kind. All Major Munn's tall talk about "a hive within a hive," "natural habitat," &c., is nonsense. Long before his day Huber employed a hive of moveable frames; and as similar frames, but improved in construction, were encased in wood fifty years ago by the late Dr. Dunbar, of Applegarth, for the double purpose of preserving internal heat and protection against cold—the "hive of hives," or "hive within a hive," is a very old affair indeed.

Frame hives are very convenient to the scientific apiarian, but it may well be doubted how far they conduce to the natural well-doing of bees. Langstroth in America and von Berlepsch in Germany invented almost simultaneously the modern moveable-frame hive, and there is not the slightest reason for supposing that either of them had seen or heard of Major Munn's contrivance.

It is to be regretted that in the new edition of Bevan's work the result of a lawsuit, whereby an attempt to upset Langstroth's patent on the ground of want of originality, should have been mis-stated. It really ended in establishing the validity of Langstroth's claims, and he afterwards obtained an extension of the term for which the patent was granted. The Major in his advertisement says that he feels "somewhat reluctant to challenge any criticisms on his alterations and additions," and well he may, for the only warrant we can find for them is an "idea" which, he states, was once mooted between Dr. Bevan and himself, that the survivor should carry on the experiments they had so often discussed by letter in regard to "my bar-frame hive."

What, then, has this survivor done, or rather undone? The first thing that strikes us is a new arrangement of chapters. For no good reason the old and most natural has been upset, and the frequent references in the various chapters to other chapters bearing on the same subject, which was one of the most valuable features in the original work, have been coolly omitted, apparently for no other end than to be spared the trouble of rewriting them. By the aid of this new arrangement the Major has managed to introduce into different places the greater part of a pamphlet published by him in 1851, and which, but for this circumstance, might soon have passed into oblivion like its predecessor. We observe also that very unnecessary alterations have been made in the language of Dr. Bevan, and sometimes, as in the case of the circular theory of cells (which we believe to be the correct one), the Major reverses the Doctor's opinions without giving his readers the slightest hint that he has done so. Major Munn has not only suppressed matter containing valuable information, but he has, by interpolations in no way distinguished from the original text, made Dr. Bevan give expression to sentiments of which he would have been ashamed. Save us all from such friends. The public now, with this mixture of Bevan and Munn only in their hands, cannot tell what belongs to one and what to the other. Discoveries that belong exclusively to Munn will be attributed to Bevan, and this will be a great pity, for to Munn belongs the credit of revealing things hitherto unknown to the best apiarian authorities. For example, he tells us at page 65, "The sole object of a colony leaving with the old queen is that she may perish after her last laying." Page 69, "Queen bees apparently cannot feed themselves." Page 74, "After the second year's commencement swarming must take place, or the death of the old [queen] will." Page 78, "Whenever this piping commences there is always a queen bee imprisoned within the large drone-like cells in the centre of the combs." Page 195, "I have evidence that the queens are compelled to make their flights twice in each year of their lives, which is but for two after all." Such nonsense, and so contrary to what are facts, ought never to have been associated with the name of Dr. Bevan. And when, we would ask, did bees become unable to elongate brood cells? or give up the practice, in the first instance, of closing them with wax? Perhaps it was at the same time that the "inclined floors" of bar-frame hives were found to be a "sufficient guard," and the collateral system met, in some measure, the requirements of the queen by leaving one side for the daughter to reign, whilst the mother "can continue her egg-laying, and augment he numbers before she perishes in the natural course of things." We cannot advert to all the Major's grand discoveries, but there is one which must not be passed over—viz., "endosmosis." It appears that larvæ require food, and in our ignorance we imagined they devoured it after the manner of other animals. It is not so; incredible as it may appear, the larvæ are nourished by absorption; the process is called "endosmosis."

We are sorry to say that we have as little faith in the truth of this great discovery as in the utility of the Major's invention. The man who fails to correct mistakes is very liable to make them. Though the text of Bevan has been much altered, "*faux couvain* (as Schirach calls it)," still appears in the chapter on diseases of bees. Why did not the Major point out Dr. Bevan's mistake, and tell his readers that "*faux couvain*" is the French translator's equivalent for "foul brood," and what Schirach really wrote was the German "faulbrut." The description which the Major gives of the disease called foul brood, its causes and mode of cure, is absurdly inaccurate. He would have done well before wasting his ink to have taken instructions on the subject from T. W. Woodbury, Esq., of Mount Radford, Exeter.

We hope it is not this gentleman referred to in the advertisement, by the name of "W. E. Woodhurry, Esq., of Exeter;" as the correct designation is known to every apiarian of any standing, whether at home or abroad. We are sure that if the manuscript or proof-sheets

had been submitted to this gentleman, he would either have corrected the numberless errors that appear in the third edition of Bevan, or recommended that the interpolations should be thrown into the fire. Whilst they relate nothing that is really new, they are radically defective in giving little or no information upon many important subjects connected with bee-keeping. When the learner has read and digested the whole work, he will find that he has both been misled and left in ignorance of much that every well-instructed apiarian knows. He will find that senseless alterations, like that at page 82, where "if the swarm be gathered," is put for "if the place," or as at page 265, where Bevan is made to say in regard to bees seeing better when flying than when crawling, "but this is unlikely," have quite perverted and contradicted the teaching of Dr. Bevan. He will be led to suppose that the evidence for the doctrine of parthenogenesis is based entirely on fallacies, and that Munn has given the doctrine a fatal blow by this single statement, "a few drones generally remain until late in the autumn."

We close the book before us without any regret, save for its publication. It brings our knowledge no farther down than the period when Major Munn first published his pamphlet, and the illustrations added to it are very bad. We would recommend those who wish to possess themselves of a copy of Bevan, to get the work as it emanated from his own hands.

Woodbridge Poultry, Pigeon, and Canary Show.—The entries for this Show close on Monday next, March 6th. We understand, should this be a success, the Show will be continued annually. A liberal prize-list offers encouragement to exhibitors.

OUR LETTER BOX.

Fowls Roosting near a Kiln (*W. G.*).—We have no reason to believe it injurious, nor do we believe it is. If the sulphur predominates too much, increase the ventilation. We do not believe artificial heat is ever beneficial. Our theory is to supply heat internally by means of food.

Price of Eggs near London (*R. W.*).—We have no doubt that near London or any very large town eggs may be sold at 1*d.* each all the year round. But it is with them as with everything else produced before its season; if you expect to make the largest average you must produce things at the scarcest time, as it is then they realise most. Thus eggs from the 1st December to the 1st February frequently make 3*d.* each, and when it was once known yours were to be depended upon they would always make 1*d.* each. You will never get two thousand eggs per week on four acres of land.

Feather-eating Hens (*W. W.*).—Some fowls have the hateful propensity you mention, but we have never found it except where they are shut up. We have never had it among fowls at liberty. We cannot help thinking yours must have been in confinement when they began. We advise you to rub all those that have been plucked with compound sulphur ointment. If they are unable to leave their roosting-house at daybreak and yet have daylight, they then begin to peck. If they have full liberty let their house be quite dark, so that they cannot see each other. When they are let out let them be scattered about as much as possible. It is probably only a small number of the birds that indulge this propensity; note them, catch them, and shut them up singly. Baskets will be large enough for them. Hens are far more addicted to pecking than cocks. We believe the bird that seemed inclined to pick himself was more disposed to scratch on account of itching.

Destroying the Vitality of Eggs (*C. H.*).—There are many modes. Some pass a needle straight through the egg, others resort to a vigorous shaking; some give the end a tap just hard enough to crack the shell. To put the egg in boiling water for a moment is effectual; but the best plan, if you want no fertile eggs, is to keep no cock.

Crêve-Cœur's Claws (*J. L.*).—A Crêve-Cœur fowl with five claws is a cross-bred bird.

Silver-pencilled Hamburghs' Markings (*A Beginner*).—The feather would be better if the markings were more cleanly cut. Such a feather as you enclose has a tendency to make what is called "mossy plumage," lacking distinctness. The earlobe should not be large, the size of a four-penny-piece is large enough. We should prefer the bird from which the feather is taken greatly to one deficient in comb and earlobe. The breast should not be as dark as the back, but it should be well pencilled. The more regularly the flight feathers are marked the better; white ones are a disqualification.

Bran as Poultry Food (*Hermit*).—We have the greatest objection to bran as food; it is worthless, and therefore it is immaterial whether it is mixed with hot or cold water. It is about equal to a meal of sawdust for ourselves. Give ground oats or barleymeal morning and evening, and some whole corn for the midday meal.

Cochin Pullet Unable to Move (*Lemon Buff*).—The pullet is in all probability egg-bound. It is a common complaint with pullets, especially with their first eggs. Pull out a flight feather, dip it in oil, pass it down the egg-passage till it meets the egg; keep on lubricating the feather and introducing as much oil as you can till the egg comes away. You may ascertain by feeling that the egg is in the passage, but it must be done gently, as a broken egg is almost always fatal. You must be very careful you put the feather down the egg-passage, as otherwise the operation is useless. If old Cochin hens are very fat, reduce the food; they will not lay while they are very fat.

Breeding Sebright Bantams (*E. T.*).—If the lacing be quite distinct the lighter colour may be only the result of the two breeds, Golden and Silver being kept together; this is frequently done. But if the lacing is getting faint and indistinct you want fresh blood. Your friend has advised you rightly, but it is a long and troublesome process, and we advise you to get a Sebright cock, a dark one, from some one who breeds carefully and makes up his breed as he goes on. From the frequent introduction of these black hens it is almost certain you will buy fresh blood. All you have to do is to see you get a dark one.

Ground Oats for Fowls—"*T. H.*" informs us that they are sold by Mr. C. Dowlen, Flanchford Mill, Reigate, Surrey.

Fowls Dying Suddenly (*S. H.*).—The time of feeding (9 A.M.) is not the cause of death. Probably the birds are too fat; you say they are "full of flesh." Give them barleymeal mashed with water; the mixed barley and rye just before roosting time. Do not give the fat you name.

Chickens' Legs Cramped (*J. J.*).—Keep them dry and warm, give a dessert-spoonful of castor oil if constipated, and feed on oatmeal moistened with ale.

Blue Rumps in Carriers and Dragoons (*F. C. Hassard*).—A full answer to this question was given in our number for January 26th, which see.

Mating a Whole-coloured Blue Jacobin Hen (*K. P.*).—If we understand you aright, your bird is entirely blue-head, wings and tail included. We are utterly at a loss to help you, not knowing anyone who has such birds. A pair of whole-coloured Blacks were exhibited at the great show at the Crystal Palace last December; perhaps the owner could help you. If you matched with an ordinary coloured Blue bird, we fear the produce would be broken-capped, and impure flights and tail, yet the experiment would be worth trying, and patience might be at length rewarded. We cannot undertake to put a price to birds. A pair of good birds would be valuable; one is useless.

Canaries at the Crystal Palace Show.—Several letters relative to our criticisms have reached us, some agreeing with our remarks, some dissenting from them, but we cannot insert them. We will readily insert opinions, however contrary to our own, upon any characteristics of Canaries, but we cannot insert criticisms upon criticisms, which necessarily lead to replies.

American Cheese Boxes for Nadirs (*A. J. F.*).—We should be glad if any of our readers who have used these boxes would state if they require any special cleaning.

REMARKS.

22nd.—White frost in the morning, fine day.
23rd.—Very fine day.
24th.—Dull morning, and during the day, windy at night.
25th.—Cold dull day.
26th.—Dull morning, fine afternoon, windy after 9 P.M.
27th.—Rain with wind in morning, wind increasing to a gale at night.
28th.—Wet in morning, fine about noon, rain again at 2.45 P.M., and till night, barometer rising sharply.

Another mild week, temperature considerably above the average, and again nearly equal to that of the first week of April.—G. J. Symons.

COVENT GARDEN MARKET.—March 1.

We have but little alteration to report; the improvement noticed last week has continued, and the present fine weather has materially altered for the better the character of those articles raised under glass, imparting to them both quality and colour. A fair amount of business is doing. The Potato trade is steady at the following rates per ton—Flukes, 100*s.* to 120*s.*; York Regents, 80*s.* to 100*s.*; Scotch, 70*s.* to 90*s.*

From observations taken near London during forty-three years, the average day temperature of the week is 50.0°, and its night temperature 32.7°. The greatest heat was 67°, on the 19th, 1826; and the lowest cold 7°, on the 10th, 1847. The greatest fall of rain was 0.68 inch.

POTATOES.

HAVING disposed of the Yankies, and waited to see if anyone had a word to say for them, and having had my opinion confirmed by so good an authority as my friend Mr. Rivers (I may add, by Mr. Radclyffe as well), I must now have my say on the English varieties I have tried, and here I get into troubled waters. I wish to be fair and impartial, to "nothing extenuate or set down aught in malice," but withal it is not easy. There is, first of all, an immense confusion in the nomenclature of the varieties. There is, secondly, the confusion created by Potatoes receiving names as distinct sorts, when they are only selections; and there is, thirdly, the undeniable fact to battle with, that soil, situation, and climate make such radical changes that it is almost impossible to predicate positively concerning many varieties.

With regard to nomenclature, it is remarkable how the same variety receives different names in different localities, and very often in the same locality; thus I believe that Webb's Imperial, Dawe's Matchless, and Glory of England are one and the same Potato; while round Potatoes have an infinite number of names. Great confusion arises also in this way—a gardener in a neighbourhood has taken great pains with his Potatoes; he acts on the principle of selection, saves only good seed, and at last obtains a superior stock; this becomes known, his neighbours get it, and, having no better way of marking its distinctness, they add his name, and then by-and-by the original name is lost, and the gardener is best remembered. He leaves the neighbourhood, little thinking that his careful culture has added another element of confusion. I will take one example: when Mr. T. C. Sage was at Sir Edward Dering's, in this neighbourhood, he paid much attention to Potatoes; he obtained a good strain of Myatt's Prolific, he carefully selected his seed, and at last obtained the very finest strain of that variety I have ever seen. Several in this neighbourhood have obtained it; to distinguish it we have marked it Sage's strain. Well, Mr. Sage has, unfortunately, left the neighbourhood, and by-and-by we shall, I venture to say, find this kind called Sage's Prolific, or some such name; and possibly it may eventually fall into the hands of some grower for sale, who, ignorant of its history, and believing it to be something new, may send it out under that or some different name. It will be seen, then, from the tenor of these remarks, that I do not believe that one-third of the new, or so-called new, Potatoes are seedlings, but selected strains. Of those that are seedlings, amongst Kidney Potatoes I believe we may trace a good deal of the Fluke and Ashleaf strain, and that where this cross has been made, the more there is of the Ashleaf and the less of the Fluke, the better the Potato will be. Instead, then, of entering into descriptions of those numerous varieties which I have grown, and a great many of which I shall never try again, I shall merely select such as I have thought ought to have something said of them; and, first of all, as I believe, *facile princeps* amongst Potatoes

The Lapstone—A cross between Myatt's Prolific and the Fluke, I should say three parts of the former and one of the latter, deriving from the former its earliness, and to some extent its delicacy. It is a Potato that will only thrive in good soil. Mr. Douglas, who can grow anything that will grow at all, says that about Ilford, Leyton, &c., they cannot grow it. I have found it do best in garden soil, although I have known it grown successfully in fields, but then the soil was good; it will not thrive in very light or very heavy soil. It is not a poor man's Potato, but I know none that can compare with it for a gentleman's table.

Carter's Ashtop Fluke is a very handsome-haulmed Potato, and the tuber is well shaped, but it has, to my taste, too much of the Fluke; many would not consider this an objection, and would be inclined to give it a trial.

Headley's Seedling, or Headley's Nonpareil.—This was sent out last season by Mr. Alfred Fryer, of Chatteris, and this season by an eminent London firm. I was inclined at first to think very highly of it, but have modified my opinion. I have detected a twang in it which does not please me, and tasting it the other day at my friend Mr. Banks's, I noticed the same again. I am sorry, for it is very handsome and prolific. For general use I am sure it must be a favourite.

Royal Ashleaf.—This is probably a selected strain of Myatt's, raised by J. Ashwin, Esq., and Mr. Rivers having carefully grown and selected the stock, it is now better known as Rivers's Royal Ashleaf. It is an early Potato, better in some soils than others. Mr. Radclyffe is a warm advocate for it, but I prefer Myatt's Prolific, which comes in about the same time.

Haigh's Kidney.—This has been sometimes strangely given as a synonyme for the Lapstone; it is not so, although raised, I believe, by the same man—Major Haigh, a shoemaker (not a military man), in Yorkshire. It is later than the Lapstone, not quite so good, but withal a very excellent Potato, and follows the Lapstone.

Yorkshire Hero.—A very handsome light-skinned Potato of which my friend Mr. Radclyffe thinks very highly. It is unquestionably a good Potato. Unfortunately I had a poor crop of it, and saved it for seed, the greater portion of which I lost by frost.

Myatt's Prolific.—Of all the early Potatoes I have tried none can compare with this, and a good many which come out under various high-sounding names are, I fully believe, only strains of it, modified somewhat by soil and situation. I have never seen so fine a strain of it as that to which I have already alluded as being in Mr. Sage's hands at Surrenden. In flavour and appearance I place it at the head of all the early kinds.

Webb's Imperial, Dawe's Matchless, Glory of England.—These are one and the same, I believe. It is a Potato which with many persons holds a very high place, very prolific, attaining a large size, and handsome in appearance, but I could never see that it possessed the first requisite of a good Potato—fine flavour. It will, however, in many

soils, from its greater hardiness, take the place of the Lapstone.

Red-skinned Flourball (Sutton's).—An enormous cropper, and a very large even-sized round Potato, too large for steaming purposes, but a good Potato for baking—better for this than any I know, except one, the name of which escapes me, which I had sent me some years ago by Mr. Thomson, then of Archerfield. Those who like a "baked tater" will be glad to grow this.

Beaconsfield (Turner).—A very handsome Potato, similar in appearance to Headley's Nonpareil, and evidently of Fluke origin. I tried it for some time, and felt inclined to rely upon it for a main crop; and where the Lapstone cannot be grown, it will be found very useful.

Harris's Nonpareil (Cutbush).—A handsome and well-flavoured Kidney Potato, a very good cropper, and apparently tolerably hardy in constitution.

King of Potatoes.—I have never been able to grow this Potato to give me any satisfaction, yet I hear it constantly praised as a fine variety.

Paterson's Victoria.—I again tried this Potato this year, as so many wondered that I could not give a better character of it, but I am unable to alter my opinion. To me it has a coarse flavour; it is well-suited for field culture and for market-gardening purposes, but I should not care to grow it for my own use. It is very prolific, and the tubers are very close home round the haulm.

Blandford Kidney.—Already grown under other names. It did not do well with me, so that I am unable to speak of its merits.

Bryanstone Kidney, raised at Lord Portman's at Bryanstone, near Blandford. Mr. Radclyffe sent me two tubers of it, but, as I said before, everyone of them went bad, so I have had no opportunity of testing it. My friend thinks highly of it.

Prince of Wales.—To the pigs, if they will eat it. Questionable if they have any taste.

Dunbar Regents.—Of all late round Potatoes, this and some other strains of Regents I consider to be the very best. A good cropper, good in flavour, and floury, suitable for most soils, and likely to please most palates.

Such are the notes I have made. I am prepared to find them controverted, for tastes differ, and localities affect different varieties, but they are honestly made from my point of view. I have received one or two kinds this year which look promising—Carter's Main Crop, a very smooth-looking, round red Potato, with very shallow eyes; and Cambridgeshire Kidney, from the same firm, which looks well; but I have now done with trials of Potatoes. I am contented, for my own growing, with Myatt's Prolific, the Lapstone, Haigh's Kidney, and Yorkshire Hero. And I have found about here a very dark-purple Kidney Potato which promises well, and seems to come in very late. For kitchen use I should take Headley's Nonpareil, Red-skinned Flourball, and Dunbar Regents.

Since the above was written I have seen Mr. Lewis's note on Early Rose. I pride myself on having Potatoes well cooked, and although I think better of Early Rose than of any of the other Yankee notions, yet in wet seasons and close soils it will not do.—D., *Deal.*

ASPECT FOR TEA ROSES.

As the articles concerning Roses which so frequently appear in "our Journal" are principally from the pens of amateurs, so the advice given is not always applicable to the practice of the professional gardener. The amateur, controlling and frequently doing much of the work of his garden himself, is more likely to advocate a system of culture or management best suited to his own taste or convenience than one adapted to the numerous requirements of a large garden. The truth of this reasoning has lately been exemplified in some communications on Tea Rose culture, one writer preferring an east wall to train his plants to, while another cares for no wall, but thinks an open bed best. Both methods may be very good, but neither is sufficiently comprehensive for practical purposes.

All who have had much work with the regular routine of dressing vases and maintaining a supply of cut flowers, must be aware of the great value of Roses, and especially of the classes known as Tea and Noisette Roses, for such a purpose. In order to have a supply of these desirable flowers as long as possible, it has been my practice to plant some of the same kinds against walls facing all sorts of aspects. Thus, I have had such kinds as Gloire de Dijon and Souvenir d'un Ami on walls facing north, south, east, and west, some plants being fully exposed to sun and wind, others somewhat sheltered by surrounding trees, and I have even planted them in obscure corners partly shut in by trees, so that I could be tolerably certain to have some of these charming flowers throughout the season for bouquets and vases.

The culture of Roses is so simple and easy that it is surprising they are not more grown than they are. Many an outbuilding or wall might have its naked unsightly surface turned to good account for such a purpose. All that is necessary is care in guarding the plants from blight or insects, protecting them in very cold or exposed situations in winter, and affording them a sound rich soil and generous treatment, for the Rose is a regular gourmand, thriving best under a liberal regimen of fat manure and rich liquids. Unlike the animal glutton, it never becomes so obese as to appear unsightly; on the contrary, its stout rampant shoots clothed with luxuriant foliage yield a proportionate profusion of magnificent stout-petalled flowers.

This high feeding can only be practised where there is plenty of wall space on which to train the luxuriant growth; where the plants are in confined situations the reverse of this treatment must be applied. In the latter case I would advocate an almost starvation system, only giving the plants just sufficient nourishment to keep them healthy, the aim being to secure miniature plants which will afford a supply of those pretty little flower buds so useful to intermix with larger or expanded flowers in bouquets.

But apart from the great usefulness of the flowers for such purposes, Tea Roses have many valuable properties, entitling them to a high rank as decorative plants. In the choicest varieties much elegance of form, both in foliage and blossom, refinement of colour, and delicacy of perfume are developed. The flowers, too, are produced so freely and continuously, that Tea Roses might be styled the Perpetual Roses with more justice than the class now known as such. Let us not mind about aspects, then, but rather try to utilise every spare foot of wall space in the production of flowers so charming, so useful, and, above all, of such easy culture.—Edward Luckhurst.

THE EARLY VINERY—GRAPES IN POTS.

The Early Vinery.—So much has been written on this subject that I cannot be expected to bring anything new to light, but I will just note a few facts which may assist the amateur. While Grapes may be grown in any glass structure, there are certain forms of structure most suitable for producing given results, and early Grapes, by which I mean Grapes ripe in April.

Our early vinery, which I had built, has given me great satisfaction. It has at one end an Orchid house, at the other the late vinery, so that it is well sheltered from cutting winds. It is 14 feet wide, has a front sash 2 feet in height, and the back wall is 14 feet high. There are four 4-inch pipes round the front and ends, and one 4-inch pipe at the back wall; every sash on the roof is moveable, so that an inch opening can be left for air at the top, and the same in front. I never give air in front until colouring commences. The wires to which the Vines are tied are not nearer the glass than 15 inches, so that in hot weather a current of air passes between the foliage and the glass. The leaves should never come in contact with the glass, for when they do I have seen them frosted in a clear cold night, and turn yellow. I have over one of the pipes troughs or steaming-trays, which are kept full throughout the growing season; these steaming-trays afford moisture to the air of the vinery, and warm water for syringing.

Our late vinery is the same as the early vinery, only there is one 4-inch pipe less in the front. It is 14 feet wide; there is at back a 4-feet path of York pavement, and the border is 10 feet wide inside, and 10 feet outside.

The soil of the border was taken out to the depth of 2½ feet at the back, and in the outside portion 3½ feet, and there is a drain at the bottom 4 feet deep. The bottom of the border was made on a uniform slope, and paved with bricks, among which thin cement was brushed into every crevice. On this were built the pillars upon which the arched front rests. Above the pavement was put a foot deep of brickbats, the smallest being kept at the top; then a little lime rubbish free of dust, and on this turves 2 inches thick, grass side downwards. The compost I used was principally formed of a friable loam, which had been stacked six months; this was broken up while dry with a spade or fork, and mixed with half-inch bones

at the rate of half a hundredweight to the cartload, some charcoal, including wood ashes, and one cartload of old lime rubbish, and the same proportion of leaves, not too far decayed, to every ten cartloads of soil. This, then, is the soil in which my Vines grow. Our soil being light, I made my border under the general ground level rather than above it, as is sometimes seen. Of course, if my soil were clayey I should have made the border above ground. Ours at the highest point, just inside the front wall where the Vines are planted, is only 1 foot higher than the ground level. I should also advise means of affording bottom heat to be provided, but not for amateurs, as with them cost is a great consideration.

Grapes in Pots.—I propagate my pot Vines two years before they fruit; the eyes are selected from the early vinery, as such start into growth with more freedom and with less artificial heat than if taken from later-forced Vines. Six eyes are placed in a 6-inch pot, and plunged in a Pine pit with a bottom heat of 80°, while the temperature of the atmosphere is between 55° and 60°. As soon as they have made three leaves they are potted singly in 4-inch pots, and when the roots have covered the ball of earth the Vines are removed into 8-inch pots, which will suffice for the season. The soil used in propagating consists of equal parts of leaf mould and light loam, pressed into the pots firmly to prevent its absorbing much water.

The plants are placed in the early vinery, and the shoots trained to the wires. By the 1st of October the wood will be ripe enough to admit of the Vines being placed in the open air, and, by the end of the month, to be cut back to two eyes. All the care afterwards required till they are again taken to the forcing house will be protection from frost, and affording a sufficient supply of water to prevent the rods from shrivelling. I have tried many composts, but for the cultivation of pot Vines I prefer the same soil as that used for borders.

At the commencement of the second year the pots are first thoroughly soaked with water and set upon the hot-water pipes. The buds will begin to start in the course of a month, when the weakest are rubbed off; the remainder will grow strongly, so that at the point where the old and young wood join roots are freely produced. I then have the Vines shifted into the fruiting pots, which are about 14 inches in diameter, sinking the base of the young wood a little below the surface of the soil. The depth of drainage is about 2 inches, one half of it being half-inch bones. In repotting, the loose roots are extended towards the outside of the pot. The soil should be warm, moderately dry, and pressed sufficiently firm, but not so much so as to prevent the water from passing off freely. The pots are replaced on the hot-water pipes, and the Vines trained to the wires, the laterals being removed when they begin to overgrow the bud. During the season of growth I supply liquid manure twice a-week, and the guano used is just sufficient to colour the water, which is applied warm.

By this treatment I produce shoots 14 feet long and 1½ inch in circumference, and have them ripened by the 1st of July. They are then placed out of doors in a north aspect to give them all the repose that the season will allow, and they receive whatever pruning may be required.

The Vines are brought into the house in November and well watered, the surface of the soil in the pots being covered with sheep dung. I use an atmospheric temperature many degrees higher than that which is necessary in ordinary cases, so I start with 65° by day and a night temperature of 55°, and maintain the same uniform heat till the buds begin to move, when the temperature is reduced to 60° by day and 55° by night. This may be thought excessive, but it is no more than enough in November. I usually take from six to eight bunches from each Vine, averaging about a pound weight. During the swelling period the Vines are well supplied with guano water, a good handful of guano being placed in a four-gallon watering-pot, which stands on the pipes so as to keep the water warm. A good watering of this is given once a-day until the berries commence to colour. I stated in my former paper (see page 97) the sorts which I grow, and therefore it is unnecessary to notice these further than to mention my reason for forcing late Grapes. I have found Lady Downe's when so forced hangs longer than any other Grape in an early vinery, so it just comes in with the Muscat of Alexandria in August, as we like to have black and white at the same time.

General Management of Permanent Vines.—In our early vinery we have Hamburghs ripe to succeed those in pots. I start the Vines in December, watering with water quite warm, and it is by no means a small quantity which they require, as four 4-inch pipes 6 inches from the surface dry up the border considerably, and when one would fancy enough water had been given, at 6 inches below the surface the soil will be found dust dry; therefore, those who have Vines planted inside should be careful that the water passes down to the drainage, before concluding they have given enough. I do not surface-dress the border inside until I am sure the water has reached every root. The outside border takes care of itself. I have not so much as covered it yet, as the roots are still inside; when wanted in the winter dry leaves thatched with straw make a good covering for outside borders. I surface-dress inside with sheep's dung and half-inch bones. This dressing, the abundant waterings, and the four 4-inch pipes 6 inches from the surface, suit the Vines well. I once a-day damp the house with liquid from the stable tank. This is done early, so that all bad smell is gone by noon. Of course I am careful that the liquid does not wet the foliage of the Vines or other plants. The benefit it does is very great, apparently in consequence of the ammonia which it sets free in the atmosphere of the vinery, the leaves becoming dark green, and a leaf of Lady Downe's which I measured last summer was 15 inches wide. I do not approve of the young wood being too strong; from 1½ inch to 2 inches in circumference I call strong.

As already stated, the steaming-trays are kept full, damping the paths, &c., and air is given as early in the day as the weather will permit, shutting up early in the afternoon. I am not afraid even if the temperature of the house be 100° in the afternoon, but a little air is admitted all night. Vines started early should have the buds thinned, and as soon as the bunches can be perceived in the points of the shoots they should be thinned, and the berries also immediately after flowering. There is no greater error, when endeavouring to secure well-finished Grapes, than cropping too heavily, especially in very early forcing. I grow my Vines on the spur system; and as quality, not quantity, is the aim, only from ten to twelve bunches are allowed to remain. I stop the shoot one leaf beyond the bunch, and when it grows again I stop at the next leaf, and so on, and the same course is pursued with lateral shoots, taking the point out as they make another leaf.

I have grown Vines on many different systems, but this I consider the best. I have, after the first stopping, allowed all the laterals to grow, but this I consider untidy. I have also not allowed a leaf or lateral to make its appearance after the first stopping. Neither plan is bad, for I have seen splendid Grapes with no stopping, and so I have with severe stopping.

I recommend that the colouring should be a slow process, plenty of air with a little fire heat being given. I protest against the barbarous system of pulling off Vine leaves to let the sun play on the bunches, to ripen them as it is supposed. I would never take off a leaf until it ripened and fell off naturally. I know this recommendation is contrary to the advice of many Vine-growers, but I have proved that the practice is wrong, for I have seen bad results follow.

I have said nothing of diseases, such as shrivelling, rust, spot, bleeding, insects, and mildew, each of which would take a paper to itself.

In referring, at page 97, to the importance of a damp and dry atmosphere, I meant the troughs to be kept full of water; as printed, the sentence reads *not* full.—C. M. McCrow, *Nash Court, near Faversham.*

VERBENAS ATTACKED WITH SPOT OR RUST. VINE BORDER.

"S. W. J.," whose inquiry is on page 139, will find nothing like a mild hotbed for his Verbenas. A few years ago I had the misfortune to have a fine lot attacked in the way described; as I used Verbenas largely at that time, it would have been a misfortune to have lost them, and having an idea that a hotbed would bring most of them round, I prepared for them a pit that was heated with hot water, filling it with leaves, well trodden down, to within a foot of the glass. Before placing the plants in it I had them gently rapped out of the pots, and the crocks removed and replaced with pieces of charcoal. The plants were then returned to the pots, and those most affected dusted with lime; next day they were well syringed with warm water; they were then kept close for a week, and afterwards the syringe was used freely, giving a little air in fine weather. In about a month I found I had managed to save about one-half of the plants, and these were growing very freely; indeed, I had more cuttings than I wanted. I let a few of them grow,

and by the middle of March was rewarded with some fine potsful of flowers, which I had neatly tied-up to four sticks placed at the edge of the pot, with three rings of matting run round, in the same way as for Mignonette. Since that time I have used 32 instead of 48-pots, for striking, putting a cutting in a pot, using charcoal instead of crocks for drainage, and placing over the charcoal rough pieces of leaf mould till the pots are three parts full. I then fill up with white sand and sifted leaf mould in equal parts, and place the pots in a hotbed till the cuttings are rooted; afterwards I keep them in a cold frame till the pit is ready to receive them again. The pit, after having been emptied of the old leaves, which were then well decayed, was refilled with fresh leaves as soon as they could be collected; on these the pots were placed, and enough fire heat given to keep out frost and cause a circulation of air in dull weather. I quite agree with Mr. Robson, that failing a heated pit, there is no place so suited to the Verbena as a shelf in the vinery.

I find Verbenas, when bedded-out, thrive best in a clay soil enriched with good rotten dung in the autumn.

I have my suspicion that the cause of the disease in some instances is watering with water containing iron.

I grow a fine lot of Cucumbers in the pit after the Verbenas are taken out, by putting a ridge of good loam along the middle, on the leaves, and planting one good plant under each light.

In reference to "W.'s" report on the state of his Vines, I should adopt his second method, and, if possible, make a narrow border inside, planting young canes between the present, and in, say five years' time, entirely doing away with the old ones. He could then make or remake the border and plant under the rafters as usual, growing the Vines planted inside for a crop till those outside could take their place.—W. Clark, *Cheshunt.*

PLUNGING POTTED CHRYSANTHEMUMS.

I have noticed recently in the Journal a discussion on some of the details of the culture of the Chrysanthemum, and that special reference has been made to plunging the pots during the summer months.

The subject of plunging or not plunging pots containing growing plants is of more interest and importance than is apparent at first sight. People have arrived at the conclusion that if the pots are plunged much less water will be required, consequently there will be a great saving in labour, and that the ultimate result will be the same. But if the matter be patiently and carefully investigated it will be found that the roots formed in a pot that has been plunged are of a very different class from those formed in circumstances where the sun and air have been allowed to play freely around and underneath the pot; and an experience of some years has led me to the conclusion that flowers and fruit of better quality are obtained from plants and trees which have not been plunged than from those which have been so treated. I am alluding now more particularly to orchard-house trees and Chrysanthemums or other flowers which we find necessary to accommodate with a position out of doors. Even in Pine-Apple culture there is difference of opinion on this matter. Happening to call recently on a neighbouring gardener, I noticed that the pots in which his Pines were growing were not plunged in the tan bed, but merely standing on the surface, and on calling the attention of the gardener to it he informed me that he did not plunge the pots, as he thought better fruit was produced when they were not plunged. Again, if Vines are required for planting out or fruiting in pots, it is better not to plunge the pots during the growing season. Of course the eyes ought to be struck in bottom heat, but after the plants are repotted they should not be plunged again, but be placed in a position where heated air can have free access underneath and round the pots; and if the plants be afforded a high temperature and be freely supplied with water there will be no difficulty in growing canes of the strongest description, which will carry a large crop of fruit the first year from the bud; the class of roots formed will remain in better condition during winter, and be better prepared to start into active growth in the succeeding spring.

My experience with the Chrysanthemum has been somewhat extensive and varied, for I have had to cultivate it both under adverse and prosperous circumstances. The system pursued here with plants which are grown for the quality of the flowers is to place the pot upon two bricks so that a current of air may pass underneath it, and plants which are grown for specimens are likewise not plunged. The Chrysanthemums here are grown for exhibition, and, as a matter of course, much attention is bestowed upon them. They are not allowed at any time during the growing season to suffer from want of water. If the pots are plunged the roots sometimes find a way through the holes in the bottom, ramify into the surrounding material, and when the plants are removed into the show house or conservatory in autumn the most useful portion of the roots is destroyed; the plants consequently experience a check from which they do not recover until it is too late for the flowers to benefit, and the quality of these is much deteriorated. I had a decided proof of this last autumn. At the exhibition of the East London Chrysanthemum Society in three of the classes prizes were offered for Pompons, and in every one of the classes the first prize was awarded to plants which had been grown in pots that had never been plunged, and the superior quality of the flowers was at once apparent. The plants were not so large as some of the others of which the roots had not only been allowed to grow through the pots, but in some instances the lower branches had formed roots, the result of such treatment being immense plants out of all proportion either to the quantity or quality of the flowers upon them. On the other hand, some exhibitors who have had much experience recommend plunging the pots during the growing season. If the plants are grown in this way there will be a considerable amount of labour saved in watering if a dry season should set in. Due precautions should also be taken to prevent the roots from growing through the pots to a large extent. In the case of amateurs who do not employ a regular gardener, and whose business occupations call them away from home during the day, plunging the pots would be absolutely necessary to enable the plants to withstand without water a sultry day in summer.

There are very few gardens where this native of China and Japan is not cultivated, and any practical details concerning it must therefore be useful to a large circle of readers. We have not heard much about new introductions this season. Readers of the Journal must have missed the usual annual report of Messrs. Salters' nursery at Hammersmith, which was of great value to those who could not make it convenient to go and judge for themselves.—[The nursery has been destroyed by one of the new metropolitan railways.—Eds.]

There is still room for improvement in all the different classes of Chrysanthemums. Of the Pompon varieties there have been very few new sorts introduced of late years. In this class the form of the individual flowers has been brought to great perfection, but there is still room for improvement in the habit of the plants. Amongst the large-flowered Chinese and large-flowered Anemone varieties many new and improved forms have been introduced of late years, but it was evident that with the Messrs. Salter the Japanese varieties, with their singular and fantastic forms, were occupying the largest share of attention. The improvement has been very rapid, and continuing, as the Japanese kinds do, to flower so late in the season, they are highly valuable for decorative purposes, however much they may be wanting in that which constitutes a florist's flower. I noted last season, as one of the finest flowers of its race I had ever seen, a new Japanese variety named Jane Salter, one of Messrs. Salters' flowers, and which received a first-class certificate. I hope to see others take the cultivation of this flower in hand, as there is none more useful at the time it is in bloom, nor is there any better adapted for the neighbourhood of large towns, or to flourish under circumstances where plants of a less accommodating nature would barely live.—J. Douglas.

A LESSON ON STRAWBERRY FORCING.

In my experience of the early forcing of Strawberries, I can find no better plan in order to insure a fair crop of ripe fruit in the first week of March, than to encourage the plants to make fresh roots previous to leaf growth. This may be done by plunging the pots in a shallow bed of fresh tree leaves—oak leaves are the best—of sufficient thickness to give just a gentle heat. Press the leaves very tightly round the pot to prevent the escape of heat. The bed should be made up either in a frame or pit, and where the plants can be brought to within a foot of the glass. Let them remain about a fortnight, or more if necessary, for the formation of new roots, but take care to give air the whole time. The amount of air should be regulated by the heat of the bed, and the state of the weather. Afterwards transfer them to either the Strawberry house or the shelves of an early vinery at work, where the plants can have plenty of light, and they will soon throw up strong and healthy sprigs of bloom, and when the flowers open they will be so well

supported by the newly-made roots that very few will fail to set their fruit.

Compare the above method with that generally adopted—namely, putting the plants into the house at the time of starting without any of this preparation, and if I mistake not the plants will run to foliage with surprisingly long leaf-stalks, even though they may be close to the glass, and the blossom, instead of being thrown up well above the foliage, will be almost hidden by it, and the first and finest flowers which should produce the finest fruit will turn black in the centre, and die, in my opinion through insufficient root action. I am more disposed to believe that such is the cause, from the plants setting their fruit almost to a flower after root action has fairly commenced; but the damage is done, as the later-produced fruit is always the smallest, many not being fit to place on the table. Professional gardeners have long ago learned the lesson, and while some of them have profited by it, many of them do not attach that importance to it which its merits deserve. I also wish it to be understood, that I do not think imperfect root action is the only cause of Strawberry flowers going blind, but it is a very common one, and should be guarded against by every possible means.—Thos. Record, *Hatfield.*

FRENCH HORTICULTURISTS' RELIEF FUND.

My dear friend Reynolds Hole has called me in his charming "Book about Roses" a French consul, as I have had a good deal to say from year to year as to the new Roses sent over from them to us. I now lay claim to being so in another and more important sense. For many years it has been my happiness to be much among the nurserymen in the neighbourhood of Paris, and I have spent many pleasant and profitable hours with them. It was no wonder, then, when I heard of the siege of Paris being undertaken my thoughts should naturally recur to those whom I felt must be some of the earliest sufferers from the cruel devastation which has fallen on the neighbourhood of the fair city; and when, from time to time, I heard of the destruction that had taken place—when, especially, the letter of M. André appeared in a contemporary, that I could no longer sit an idle though not an unconcerned reader of those great sufferings, I consequently wrote and suggested that an appeal should be made in their behalf. I am thankful to say that this has been most warmly taken up. The Council of the Royal Horticultural Society has seconded the movement, and everything, as will be seen by the advertisement in another column, has been put into a fair train.

I have received letters from Paris, speaking in most grateful terms of this movement, and I now desire to make my appeal to all lovers of gardens to aid in this good work. I know you have all, my good and kind readers, done your part already. I know but little of the whole race of gardeners, professional and amateur, if they have not been already contributors to some of the many agencies at work for the relief of French distress; I do not want to divert, God knows, one single rill of that mighty stream of charity which is ever flowing in our dear country, but I want to tap another spring, believing it will in no way drain the others. Imagine what it would be for your own gardens to be torn and trampled by the troops of invading armies; your greenhouses and frames pulled to pieces to make firewood of; your well-trained trees cut up to make gabions; your dwelling-houses ransacked, and then tell me, Can you refuse to help those who have thus suffered? No, I am sure you cannot, and so I rely on your kind co-operation. Let none be deterred because they can only give a trifle, for every little makes a mickle, and the few postage stamps will be as acceptable from those who can give a little only as the well-filled cheque from those who are wealthy. The cause is a good one; give for that reason. If you want another, remember that it will be only another proof of the sympathy of England, which will be thoroughly appreciated by our French friends; and may I say that if ever I have been enabled to give any information that has been either agreeable or profitable, I may ask in return that you will favour this movement? As I am ready to receive subscriptions I had better, perhaps, not use my usual *nom de plume* of "D., *Deal*," but sign myself—H. Honywood Dombrain, *Westwell Vicarage, Ashford, Kent.*

A meeting was held on Tuesday last at the rooms of the Royal Horticultural Society, South Kensington, in furtherance of the object of raising a fund to relieve the French horticulturists who have suffered from the ravages of the war. The meeting, considering the short time the matter has been before the public, was a full one, and the liveliest interest in the success of the undertaking was exhibited by those present. Mr. G. F. Wilson, F.R.S., was in the chair; and there were present Mr. Charles Lee, Mr. H. Veitch, Mr. Cutbush, Mr. Bull, Mr. Laing, Mr. Williams, Mr. Turner, Mr. Standish, Mr. Robinson, Mr. Beale, Mr. Eyles, Mr. Richards, Dr. Masters, and Dr. Hogg. M. Wauthier, of Paris, was present, representing the Société Centrale d'Horticulture.

The Rev. H. H. Dombrain, the Honorary Secretary, read several letters he had received from Paris relating the great suffering our fellow horticulturists had undergone, and the total destruction of property which many of them had sustained by the late war. He also stated that he had been in communication with the Lord Mayor with the view of participating in the Mansion House fund, and that his application had met with a favourable reception; but the meeting were strongly of opinion that before any aid could be expected from that fund the horticulturists themselves should make a special effort to alleviate the sufferings of those in whose interest their sympathies had been excited.

Several subscriptions, varying in amount from 1s. to fifty guineas, were announced as having been received, and these, together with those contributed by the meeting, amounted to no less than £261 14s. The following deputation was appointed to wait on the Lord Mayor at the Mansion House—Mr. Wilson Saunders, Mr. Marshall, Mr. G. F. Wilson, Dr. Hogg, Dr. Masters, and Mr. Harry Veitch.

We have already stated how cordially we approve of this movement, and we trust that all our readers, however limited their means, will to the best of their ability unite in trying to alleviate the distress of those industrious and innocent sufferers, many of whom are known to us as personal friends.

A large number of circulars has been printed for distribution, and the members of the nursery and seed trades in the provinces are earnestly invited to lend their co-operation by circulating them in their several districts. Any quantities that may be required can be had on application to the Secretary, Rev. H. H. Dombrain, Westwell Vicarage, Ashford, Kent.

DOUBLE-FLOWERED PELARGONIUMS.

Mr. C. M. McCrow, in page 63, asks for the results attendant on plunging the above in borders, and I have much pleasure in communicating my experience. During the last two summers, I have tried the plants in borders with and without pots, and much prefer them in the latter. Last autumn I took up twenty plants from borders, placed them in pots just large enough to admit of the roots being crammed in, and set them in the same house as my autumn-struck plants, and although I lost upwards of a thousand good Pelargoniums through frost, only two of my old plants perished, and I could now take nearly one hundred good cuttings. I may add that the bloom of the plants not kept in pots was much finer than that of the others, and the plants did not require water in the summer, as they rooted very deeply.—J. Wallis.

PRESENTATION OF A TESTIMONIAL

TO MR. ROBSON, GARDENER TO VISCOUNT HOLMESDALE, M.P.

The Editors and the many readers of The Journal of Horticulture will be gratified by knowing, that their old and much-esteemed friend, Mr. Robson, late President of the Maidstone Gardeners' Mutual Improvement Association, was presented with a handsome and valuable testimonial by the members of the above Society and their friends, on Wednesday, March 1st, at the Rose and Crown Inn, Maidstone.

Mr. Frost, the well-known nurseryman (the President for this year), took the chair. Mr. Davis, the founder, and father, as he is commonly called, of this prosperous Institution, occupied the vice-chair. The members in all, including honorary and ordinary, amount to over four hundred. A great number were present on this occasion, many of them from a long distance. The Chairman in modest but appropriate terms spoke of Mr. Robson's well-known high qualities both as a gardener and private gentleman, setting forth in no exaggerated measure the desirability of commemorating in some slight way the valuable services of Mr. Robson, not only to the Maidstone Gardeners' Society, but to all gardening and gardeners.

The testimonial was then handed to Mr. Robson by the Chairman. It consisted of an elegant gold watch with a suitable inscription, a massive gold chain, a purse of sovereigns, and a book beautifully embellished with the names of the sub-

scribers to the Robson Testimonial. Mr. Robson, who seemed much affected by the kindly feeling evinced towards him by all present, returned warm thanks to all, dwelling on his own undeservedness of such a mark of esteem as he had just received. —A Gardener, one of the Committee of the Society.

CULTIVATION OF THE JONQUIL—RAISING CONIFERÆ FROM SEED.

Fashion is a great power, ruling the gardener as well as the milliner. At the present time spring flowers are as much the rage as bedding plants were a short time ago, and it might, therefore, have been expected that the Jonquil would have resumed the place it occupied among our floricultural forefathers; yet it is but seldom seen now-a-days in English gardens or English forcing houses, and, judging from my own experience, I believe the reason to be that its proper mode of cultivation is very generally unknown. After many years of failure I have at last met with success, and it may interest some of your readers to learn how it is to be attained.

The largest and best Jonquil bulbs, offered by seedsmen with other bulbs in September and October, cannot be made to flower decently in the following spring, either in-doors or out, by any method I have seen tried, and my gardener has tried everything he or I could think of. If planted in the open ground they will produce their leaves in the following spring, and a spindly flower here and there early in the summer, but if the bed has been deeply dug and well manured, and the Jonquils are left untouched for a couple of years to establish themselves in it, they will throw up their leaves in the autumn, and when they do this they will bloom profusely in the following month of April, and scent the whole garden. The leaves should become yellow in the month of June or July and die off; roots then transplanted will produce leaves and flowers in due season. The leaves show six months before the flowers, but they are perfectly hardy, and remain untouched by the winter's frost.

For forcing, the larger bulbs should be potted as soon as the leaves have faded, and the pots should be plunged in a cold frame till November, when the young leaves will be 6 or 8 inches high. Brought into the forcing house in succession they can be bloomed throughout February and March. I have no doubt that a similar mode of treatment would answer admirably with Polyanthus Narcissus, and though I have not yet tried the experiment, I mean to do so next season.

I want the advice of some one of experience in the following matter. In the case of Cedars and other large-seeded Coniferæ the number of plants I raise, as compared with the number of seeds I sow, is exceedingly small. Of course there is always a certain proportion of bad seed that does not sprout at all, but where the seed does germinate it seems a mere toss-up whether the extension of the stem forces the rootlets or the cotyledons out of the ground, while even when the cotyledons come up properly they are often strangled by the hard seed shell, from which they are unable to disengage themselves. I usually sow on the surface of a prepared bed, and cover with a light sprinkling of leaf mould, but I have tried deeper sowing without any lessening of these freaks of Nature, while there was, of course, a smaller per-centage of germination. A word from the wise in this matter would be much esteemed by—A. B. C.

ICE versus GLASS, AND OTHER THINGS.

Mr. Pearson advocates narrow glass. I am sure he is wrong. This winter has been a trial, if there ever was one—fierce frost, fiercer snow, fiercest wind, and yet I have not lost a single pane of either the 25 inches or 20 inches wide, but several of the 9 inches. The reason is evident; the wide panes spring, and the freezing at the laps does no harm. Then, the snow slides off the wide glass, whilst the rafters keep hold in the case of narrow panes.

Then about leaving potted trees out of doors in winter, I do not think it is a matter of any consequence, provided the soil in the pots has been kept dry during the autumn, and is also safe from frost. I have at present two long walls of piled seedling Peaches, and they seem to be perfectly safe; but two or three strong old trees left out through neglect have been cut to pieces, ripe brown two-year-old wood looking as if it had been boiled.

Then some one advises a correspondent to empty his hot-water pipes frequently in order to avoid "furring." Now, if there is lime in the water, the heat drives off the carbonic acid that held the carbonate of lime in solution, and down goes the lime, leaving the water so much purer; therefore, in such case, as little fresh water as possible should be put into the pipes. But why not say at once, Use rain water invariably for filling the pipes?

I see we are likely to have a good deal of aphis this year, for in spite of thorough washing as soon as the leaves fell, and again before starting, I have had beginnings on almost every tree; but, of course, I do not allow a day to pass without snuffing out any such visitors as may appear; last year I hardly ever saw one, certainly none till they came in from the outside.—W. Kingsley, *South Kilvington.*

Thanks to "R. F." (page 49), and to Mr. Pearson (page 63), for their excellent remarks on the subject of an evil at all times annoying to the gardener, and especially in winter. The breakage of glass is never agreeable, attended as it is with a considerable amount of drip, to say nothing of the trouble, annoyance, and cost of repairs.

Of the causes of glass cracking from frost, I consider "a wide lap" the chief, and I think sole one. Size of pane has no influence whatever on the liability to breakage by frost, the breakage being entirely dependant on the capacity of the lap for holding water, which in severe weather is converted into ice. The greater the lap the more water will lodge between the panes where the one overlaps the other, and the greater will be the quantity of ice, and consequent liability to breakage. This has never been better exemplified than in the present year. We have two Peach houses glazed with 26-oz. sheet glass, in panes 40 inches by 17½ inches, and the lap is one-eighth to three-sixteenths of an inch, in no case exceeding a quarter of an inch, and not one pane has cracked; but in some pits with the panes 15 inches by 11 inches there are several panes cracked from frost, because the laps are more than double the breadth of those in the Peach houses. Again, in a greenhouse, with panes measuring from 24 to 30 inches by 12 inches, there is none cracked by frost, for the lap is as nearly as possible a quarter of an inch; but in some vineries with panes which may be 12 inches by 9 inches, the breakage is very great, for the laps are not less than half an inch, and some three-quarters of an inch.

Thick glass, as Mr. Pearson says, is no safeguard, for it will break just as quickly as thin, if the lap is so great that water lodges in any considerable quantity. I have known quarter-of-an-inch rough plate broken by frost quite as extensively as 15-oz. sheet glass.

Of glass annealing I known next to nothing. It is, no doubt, a very important part of glass manufacture. Some glass I know is very inferior; but is not inferior glass, presuming it is properly annealed, more suitable for horticultural purposes than the best? For instance: Is not 3rds quality, 21-oz. British sheet at 4½*d.*, superior to the best quality at 10*d.* per superficial foot? The liability of the best quality of glass to scorch the foliage beneath it is said to be so great, and the expense so much more, that it is rarely tried, and where it has been tried it is considered disadvantageous. This being the case, is it not folly to glaze with more than 3rds quality glass? If the 3rds or 4ths qualities are so badly annealed as to be very liable to crack, or must all crack, as Mr. Pearson says, would it not be better, instead of using a better quality of sheet, to use rough plate three-eighths or even half an inch thick, which for squares containing 9 feet will not cost more per foot than the best quality 26-oz. sheet? Cheap glass is, in my opinion, a great evil, and especially thin glass, which I consider occasions a great loss of heat. The object of all glass is the retention of heat accompanied with the transmission of light to the plants, fruit trees, &c., enclosed; and the cooling of the enclosed atmosphere is dependant in a greater measure than many of us suppose on the thickness of the glass. Rough plate three-eighths to half an inch think, I find, makes a very considerable difference in the temperature as compared to a house glazed with 21-oz. sheet—fully 5° in favour of the rough plate, to say nothing of the more equable temperature. Thick glass does not reflect nor refract more of the sun's light and heat than thin, but only causes its diffusion, and on that account prevents scorching, which is dependant more on the what we call the clearness, but in reality smoothness of the surfaces of the glass, than on its mere thickness or thinness. Polished plate a quarter of an inch thick will scorch quite as much as the best quality of sheet glass. We have in use polished plate a quarter of an inch thick, rough plate (ground on one side) three-eighths and half an inch thick, rough plate

three-eighths and half an inch thick, and sheet, 26-oz., 21-oz., and 15-oz., with crown glass, and all the breakage from frost is in the last three descriptions, none of the other four being in any way acted upon injuriously by frost. It is only right to say, that of the 21-oz. not one pane per cent. is cracked, but of the 15-oz. most, and they are the smallest panes with the greatest laps, consequently I attribute all the breakage to the laps.

A lap of any sort I consider a great evil. Laps are causes of drip, let out a great amount of heat, and in time there is formed an ugly dirty band at the lap, or where the panes meet, and this is anything but neat, and is a great propagator of moss on the glass, which obstructs not only the sun's light, but heat, to a greater extent than many imagine. Mr. Pearson condemns "jumped" joints—*i.e.*, the edges placed together; but, then, as he says, "in stormy weather a roof so glazed admits water at every joint." This statement I can confirm; for the ends of a greenhouse, to say nothing of the roof, in which the glass is so arranged, admit a remarkable quantity of water in wet windy weather. Notwithstanding, I believe it is the true principle of glazing, and though I would not advocate wider panes than 15 inches for 21-oz. sheet, I would in all cases of glazing with more than 26-oz. sheet, or with plate glass rough, or ground and polished, have no sash-bars but simply rafters, 2 feet 3 inches to 2 feet 6 inches apart, for 32-oz. sheet and quarter-inch plate, whilst for three-eighths and half-inch plate I would have the rafters with 3-feet intervals. We have some polished plate in panes 4 to 5 feet, by 3 to 4 feet, and they are in appearance very much superior to those of which four would be required to make one of the other. The glass I would have half as long again as wide, and divide the lengths so as to have the panes equal in size. Where the panes met directly I would have a chamfered cross-sash but without the rebates, having it quite flat on the upper surface, and so let into the rafters that its upper surface would be level with the bottom of the rebate in the rafters, which need not be more than half an inch or five-eighths of an inch wide, and a quarter of an inch deeper than the thickness of the glass. The cross-sash need not be more than an inch wide—three-quarters of an inch would be sufficient—and should be so placed that the panes would meet exactly in its centre. Bed the glass in white lead, also the small cross-bar, and the lead will be forced through and fill-up any opening where the panes meet; and outside, over each joint, we have only to place a strip of lead-leaf no thicker than lead paper so as to cover the joint, and this being white-leaded on its side next the glass, and where it covers the joint, will endure, nobody knows how long. Outside we have continuous-"looking" glass, inside neat, French casement-like panes, no cold air blowing in, nor heated air passing out, and there is no lap for the water to pass under, consequently no ice, no frost-cracked squares. This mode of glazing would answer for smaller as well as larger panes, only if the glass be 21-oz. or 15-oz., it ought not to be wider than 15 inches for 21-oz., and 12 inches for 15-oz., and the cross sash-bar may be smaller, or dispensed with.

Mr. Pearson's preventive—namely, having the glass cut with a slight curve, I have no faith in. I remember its being lauded a quarter of a century back, and have seen more than one structure glazed in that way. It was thought it would prevent drip by taking the water to the centre of the panes, and so keep it from being blown inwards and running down the rafters in stormy weather. This mode was principally used for curvilinear roofs, but fell into disuse from the waste in cutting, the difficulty in repairing, and, as I remember, from the frequency of broken glass. Unless the lap is small there is not much difference between glass cut with a slight curve and that cut straight; both hold water enough to form sufficient ice to break glass in frosty weather. The capillary attraction of the lap is fully as great in panes cut curved as those cut straight, as regards the water under the lap, but that coming on the outside is conveyed by the upper cut-edge to the centre of the pane, and may run off, but if the lap is not full by capillary attraction, the water passes under the lap, and there remains until it is displaced by wind, or augmented by more till the weight is greater than capillary attraction will retain.—G. Anney.

CALCEOLARIA CULTURE FOR BEDDING-OUT.

I have been a successful cultivator of Calceolarias, for I scarcely ever lose a plant during the summer. I differ very much from Mr. Clark, who says, at page 137, "I insert them in large 60-pots, six in a pot, using equal parts of leaf mould, drift sand, and chopped moss, with plenty of drainage." This amount of trouble and time I should not like to expend. I use a plain wooden pit facing the south, 3 feet in depth at the back, and 2 in front; I fill it with decayed dung, placing over it 6 inches of loam beaten firmly. I insert the cuttings during the last week of September and the first week of October, keeping the boards shut down, and sprinkling every night and morning in fine weather. Should it be showery I tilt the lights and let the cuttings have the rain. It must be understood that the boards are on hinges, which makes it a very useful pit for bedding stuff, especially in the spring.

In this pit I keep my Calceolarias till the middle of March, pinching them once; then I remove them to the openest plot in the kitchen garden; there I open a trench 4 feet wide, placing the soil on each side as a bank for protection, at the same time wheeling in 4 inches of decayed dung, and forking it up with the soil at the bottom. In this I plant the Calceolarias, leaving them there till the second week of May, when I remove them to the flower garden, taking up each plant just ready to flower with a fine ball of earth; the check they receive in removing them throws them into flower. The only evil of which I have to complain is that they cease flowering so early in the autumn; and, like Mr. Robson, I should be glad if anyone would recommend some method by which constant flowering could be insured. I shall this season try cutting off the first blooms, for the plants come into flower long before the Geraniums. I should like to know if anyone has tried this method, for it would be a great boon if we could find one which would prolong the Calceolaria's flowering, for without it large flower gardens would not look much, as we have no substitute equalling it.

The varieties I use are Kayii, an old and well-known kind, and Aurea floribunda. The former is that which I would recommend to everyone who has experienced any difficulty in the cultivation of the Calceolaria; it is of strong, robust growth, and is an excellent companion to Stella Geranium. It is the variety I prefer for extensive flower gardens.

The reason I object to use glass lights over my Calceolaria cuttings is they become drawn up, and will not withstand the rough treatment they are exposed to in planting out in the kitchen garden. If grown properly they need no protection after the middle of March; a few deal boards placed across the pit will save them from the cutting wind. I have no doubt that the failures of which so many complain arise from what is called coddling, for however much air is given, the plants are always weakly under glass.

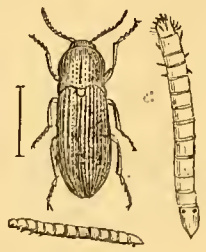
I visited a gardener friend last March, and in looking through the frames he pointed out to me the fine Calceolarias he had; they were so at the time, but they were very weak. He transferred them to a pit in the kitchen garden the same as mine, and there they received a severe check, but he brought them through it, and planted them out in the middle of May as fine plants with good balls, but in July he had not one-half of them alive, and his ribbon borders were consequently disfigured. For this reason I condemn glass lights for the growth of the Calceolaria, and anyone trying a boarded pit will find himself on the right side.—E. Eames.

SOME PREDATORY INSECTS OF OUR GARDENS.—No. 4.

Certain persons when they found that the worthy gentleman Mr. Micawber purposed going into the Medway coal trade, concluded at once that it would be decidedly necessary he should visit that agreeable river. Possibly they were right; but I am sure I was justified in coming to the conclusion that when I purposed writing something about the wireworm (about as definite a phrase as if one were to say, "the caterpillar"), I had better make personal acquaintance with one. True, I had remembrances of interviews with certain "grubs," in years gone back, reputed to be "wireworms," yet I could not have drawn a portrait of one of these from memory either with pencil or pen, nor did any notable fact remain in connection with the same, saving and excepting that one was shown to me by a gardener, whose naturally long visage gained so much extra length from the disgust with which he viewed this special enemy, that had I possessed a portable photographic apparatus I should have entreated him to remain motionless, that I might secure a "phiz" that was remarkable if not admirable. Books are all very well, but they have their errors. What was to be done? The weather precluded country excursions; could a "wireworm" be obtained close at hand? I recollected

that in my suburban garden plot, brick-surrounded and smoky as it is, I had seen during the previous summer indubitable "skip-jack" beetles, of small dimensions, and it followed as a natural inference, that it would be by no means unlikely that larvæ were feeding not very far off from where imagos had been seen. Out with the spade, drive it into the peculiar composition which in town gardens we call mould! Alas! recent frosts have rendered the ground rather unmanageable, and after some efforts I fell back for consolation on the "fox and Grapes" fable—there are no wireworms here, or, if there are, they won't be worth the trouble I am bestowing upon them. Deserting the garden for the library, I see no reason, nevertheless, for dropping my design altogether; something may be said historically upon the wireworm now, as this is the season of the year when in gardening operations it is occasionally unearthed, and as very shortly, with the returning warmth of spring, its ravages will be more considerable. At a future date some additional facts may be appended regarding this rather memorable insect.

The wireworm or wireworms, for they should certainly be spoken of in the plural, though, perhaps, greater enemies to the agriculturist than to the horticulturist, exert very injurious influences in kitchen gardens during some seasons. More particularly are they likely to show themselves in ground which has been recently converted from pasture to garden ground. And it is very necessary to bear in mind that other creatures besides the Elater larvæ have been, and still are, designated by this name. Millipedes and centipedes have been called wireworms, and also the larvæ of some of the Tipulæ. This is coming rather near the mark, but still incorrect. Wireworms are the larvæ of certain beetles belonging to the family Elateridæ, a section of the Coleopterous order, including some remarkable insects. In America there are phosphorescent species, mostly belonging to the genus Pyrophorus. One very common in Mexico and Brazil (P. noctilucus) is called the Cucujò. These are used as adornments for the hair, and shed sufficient light to enable one to read. Like the glow-worms, they can modify the light at will, by interposing a membranous film. This luminosity appears to come from what a writer calls its "phosphorescent bumps," though the abdomen emits a light also. But this circumstance is chiefly interesting when taken in connection with the fact that one of our British Elaters, if not more, has a similar power. Mrs. Cox has referred to this species as the wireworm, and alludes to the injuries it produces in hotbeds and greenhouses, where it does mischief, especially to Melons and Cucumbers. No doubt this is true in a measure, yet an investigation of the works of various authors who have published their observations on the different species of Elater, leaves us in some difficulty as to which should be most deeply stigmatised amongst them as injurious to garden or field produce. Modern entomological science, as we know, tends to the multiplication of genera, and the old genus Elater has been split up considerably. They are, in the perfect state, noticed by even the generally unobservant, and popularly known as "skip-jack," or "click" beetles. Some have received distinctive English names—merely the echoes, though, of their Latin appellations, such as the acuminated click beetle, the long-necked, the tawny-legged, the satin-coated, the marginated, the red-tailed, and so on. This matters not much, however, to the gardener, who heeds not very much minute distinctions; so long as the general habit of the species enumerated be the same, or nearly so, he will be content to say, modifying Byron's quotation, "Arcades ambo"—that is, translating freely, "blackguards are ye all."



Wireworms.

Really destructive as are the wireworms while in that stage, the beetles they produce are highly curious, their saltatorial propensity enabling them to execute manœuvres which are puzzling, yet easily understood when explained. Kirby, commenting on Cuvier, points out that his observation regarding vertical leaps, which he said could only be taken by birds and by man, is incorrect, since the Elaters very frequently (though not always) spring in this manner. Hold one of these fellows tight so that he cannot move, and he still produces his peculiar rap, and you are surprised at the wonderful amount of strength contained in so small an organisation. Were it not for this natural provision, individuals of this tribe when they fell upon their backs would have exceeding difficulty in regaining their legs, and a continuance in such a posture beyond a certain time is death to beetles, as to many other insects. A beak at the extremity of the prosternum is the main agent in the movement. The head and abdominal extremity touch whatever surface the beetle may be resting upon; then, as it unbends, this point strikes into the hollow of the ring next to it, and as the back comes down to the level, the jerk mounts it into the air to a distance of 6 or 8 inches or more.

The larvæ or grubs of the different species under consideration are assuredly wiry enough to merit the common name, or, at least, the first half of it; the second is less appropriate, since they have six very distinct legs. A figure which is given in Figuier's "Insect World," representing one, is probably much too dark, the colour being, I believe, greyish white usually, or a yellowish brown in some instances noticed. The wireworm has been compared to the meal worm, being slender, flat, and shining; the legs are short, adapted to the burrowing life it leads, and at the extremity is a tubercle, which serves as a fulcrum in case of need. Many years ago, Kirby, in his investigations into the economy of predatory insects, ascertained that in Norfolk and Suffolk Elater obscurus (of Marsham) committed extensive ravages. More recent observers in Scotland describe this as being still a very injurious species there. "Indeed," says McIntosh, "the presence of wireworms in soils cropped with autumn-planted Potatoes is more to be dreaded than the frost." The species named by Linnæus E. lineatus has been repeatedly commented upon as one of the farmer's pests, though its ravages have been remarked as extending also to gardens. In addition to the tubers of the Potato, Carrots, Turnips, Cabbages, and Beans, have in turn suffered from the subterranean work of the larvæ of some Elater. That choice and troublesome plant, the Asparagus, has its buds perforated under ground, while the offender not unfrequently escapes scot free, for owing to the mole-like life led by the wireworms, the work of their jaws is ascribed at times to worms, slugs, &c. It has been stated, too, that like the cockchafer, some at least of the species exist for several years in the larval stage, resting, at least partially, during the winter season. Not at all improbable is it, however, that under certain circumstances they feed on through the winter, as is known to be the case with many subterranean larvæ.

Deep digging has been recommended as tending to reduce the numbers of the wireworm, but it is only a very partial remedy, and of limited application. Trap-setting done at the proper season is of much advantage. The best plan seems to be that of placing slices of Potato on the points of sticks, and burying these beneath the ground to the depth of some inches. Every day or two they should be pulled up, and the "catch" disposed of by burning. Traps on the surface of the earth have also been tried with some success—not only pieces of Potato, but also slices of Turnip, and the stalks of Lettuces. A writer on gardening states, that by persevering in these modes he captured many thousands in a fortnight's time in a Carnation border, which was infested. Spirit of tar and the refuse lime of gasworks have been also used as destructive agents where they could be applied. But the oddest remedy, perhaps, is that which checks the ravages of the wireworm by cramming it to death with luxurious food. Rape cake broken into small pieces is drilled into the ground—say a few weeks before Carrots are sown, where that vegetable is in danger. This is most effective, so it is said, in dry seasons, and the larva devours this food until it dies of repletion. Perhaps so, yet I am half inclined to suppose that its death is hardly to be accounted for on the repletion theory, since over-gorging does not appear to prevail in the insect world. It may be that the oily bait is unwholesome to its constitution, though pleasant to its palate.—J. R. S. C.

ENTOMOLOGICAL SOCIETY'S MEETINGS.

The Anniversary Meeting of this Society was held in the rooms of the Linnean Society, at Burlington House, on the 23rd of January, when Mr. A. R. Wallace was re-elected President, and the routine business transacted. A satisfactory report of the Society's accounts was read, and the President delivered an annual address, reviewing the entomological proceedings and publications of the past year, and discussing at great length a paper on the geographical distribution of Coleopterous insects lately published by Mr. A. Murray, in the course of which the President dissented from most of Mr. Murray's views. A vote of thanks to the President for his address was passed, and the address has since been published and distributed among the members.

The February Meeting of the Society took place on the 6th of

that month, Mr. A. R. Wallace in the chair. After the appointment of Vice-Presidents, election of new members, &c., Mr. F. Bond exhibited some rare Moths from Scotland, including Pachnobia alpina, *Westw.*, Gelechia horeella, Larentia cæsiaria, and some very dark specimens of Thera juniperata; also a portion of the web, 2 or 3 yards long, spun by the gregarious larvæ of one of the small Ermine Moths, Hyponomenta Padella, likewise a specimen of Vanessa Atalanta in the winged state, which still retained the head of the caterpillar enclosing the head of the butterfly; also four singular specimens of the common Brimstone Butterfly, Gonepteryx Rhamni, in which the wings exhibited a greater or less mixture of the dark and light colours peculiar to the two sexes, as well as a series of photographs containing highly magnified representations of the eggs of various bird parasites, some closely resembling sea anemones, from slides prepared by Mr. Norman. The Rev. H. S. Gorham exhibited Oxytelus fulvipes, *Erichson*, a Beetle new to Britain, from Staffordshire.

Professor Westwood exhibited specimens of a minute water Bug (Cocixa ovivora, *Westw.*), which is very destructive to the ova of freshwater fishes in India, proving a great enemy to experiments in pisciculture in the east; also drawings of a singular species of Scale Insect (Coccus stellifer, *Westw.*), injurious to the leaves of Cypripedium niveum, from Siam. The male scales are extended into eight radiating plates tipped with white, and with a white rib down the centre of each. The Professor had fortunately extracted a winged male from beneath one of the scales.

Mr. A. Müller exhibited some curious galls on species of Oak from Tangiers, collected by Mr. Blackmore; and Mr. Butler read descriptions of a new genus and seven new exotic species of Butterflies belonging to the Pierides.

DINNER-TABLE DECORATION.—No. 2.

I now come to another feature in dinner-table decoration, and that is the use of materials different from those which the gardener usually employs; one of these is the use of large sheets of mirror glass laid flat on the table, the various kinds of ornament or requirements of the table being placed upon this glass. Here we have sheets about 5 feet long and a little less than 2 feet wide; these we find quite wide enough. There are other sheets which are shorter, in order to fit the length of table wanted, and as many of these as are necessary are laid along the centre of the table upon the naked cloth. I ought, however, to observe that the sheets of glass are fitted to slight frames sufficient to move them with, and rest upon a very thin boarded back perfectly flat, so that no weight likely to be put upon them will break the glass. The frame is about an inch thick at the edges, and not more than half that in width. On the side next the glass this edging in our case is simply painted green, as we invariably surround it with a bordering either of Lycopod or some made-up wreath of flowers or evergreens, generally, however, with the trough; and it has been thought good taste to stick in sprigs of a graceful small-leaved plant, say Panicum javanicum variegatum, sprays of Pampas Grass, or something of the kind, but nothing higher than 4 or 5 inches. These being reflected by the mirrors look well. At Christmas a wreath of Holly all round has also a good effect. The stands of flowers, the candlesticks, and other things proper for the centre of the table may all be placed in their usual position; but care should be taken to hide the joints of the frames where the portions of glass meet; a stand or something similar will help to do this. No further bordering on the table is needed; the frame, either of evergreens or flowers, to the looking-glass is generally quite sufficient. Besides the stands in their usual places, some small baskets of flowers of a neat and effective kind, that will be mentioned hereafter, may also have a place if there be room. It is, however, not advisable to crowd the looking-glass, but to leave plenty of space for the flowers to be reflected from; a little experience will teach when enough has been placed on the glass. It ought not to be so thickly studded with objects as the cloth might be, otherwise the purpose for which it is used—namely, to reflect the objects upon it, is to a great extent defeated. When many superficial feet of mirror are used in this way, the number or efficiency of the lights ought to be increased, for, to borrow a humble phrase, it is astonishing how the glass seems to swallow up the light, certainly more so than a green cloth or a mass of foliage.

The seeming necessity for using flower-stands alternately with the candlesticks having been frequently alluded to by me in previous articles, I may add that the kinds we have here are partly of the March design and another of about equal height. These we dress in the usual way, filling the bottom dish mostly with short-stemmed flowers fully expanded, while those for the top are of a more feathery description, and some pendent ones hang over the edges of the top dish, for which purpose nothing exceeds Fuchsias or the berries of Rivina humilis. The most effective flower for the bottom is the beautiful star-shaped Eucharis amazonica. I am not sure if this does not exceed Water Lilies; certainly it does so in one very important feature, for the flower does not shut up at night when its beauties are most wanted. It can be had in midwinter, and when cut keeps longer, I believe, than any other flower I know. The Eucharis has been with us the most valuable plant grown for the purpose, and a few blooms will go a long way, as it is not advisable to crowd them. Of course a certain amount of green in some form is necessary, including the invaluable Maidenhair Fern, which ought to be kept in reserve till the last, as it withers so soon. Covering the edges of the stand is best accomplished by foliage that will hang over in a natural manner. Well-selected leaves of Tricolor Geraniums do very well, while for a change we have sometimes the Palm-looking leaves of Helleborus fœtidus, and sometimes the much larger yet equally elegant foliage of the common Berberis Aquifolium, especially when a sufficient number of rich crimson ones can be procured. In hue these leaves far exceed those of any Dracæna I am acquainted with, and being bright and glossy they look well at night. In summer an abundance of materials can be had, but often in winter everything that can be turned to account is brought into requisition, and a very common plant will in many cases look as well as the occupants of exotic houses. We have for several winters used along with other things the berries of some large plants of Cotoneaster Simmondsii, which are growing against the walls of houses facing the north. These bright shining berries, of a clear orange colour, look well when numbers of them are clustered on the spurs of the tree, as they are when it is grown against a wall and properly pruned, but they are of little use when it is grown as an open bush, and the birds do not seem to attack them so readily as the fruit of the Pyracantha and other Cratæguses. A set of troughs dressed with the short trusses of Laurustinus blooms and a few of these tufts of berries put in amongst them, look very showy, the edges of the troughs being hidden by overhanging Ivy leaves. Holly berries are more difficult to manage, but they, too, are used, and on one particular evening Mistletoe may be worked in; still I am no advocate for indiscriminate mixtures, nor, in fact, for mixtures at all, except it be of only two kinds. Perhaps in the tops of the flower-stands this rule may be disregarded, but employing too many different materials there is also objectionable.

Little things often materially augment the general effect, and we have frequently thrown in some green when none was near, by putting a star or other device underneath the candlesticks, generally using selected Portugal Laurel leaves that are flat. A portion of their base being cut off, they are sewn upon a piece of white paper or card with their points outwards, care being taken to keep the whole as flat as possible. These stars are useful in many ways. Sometimes when plants are substituted for the flower-stands, and the pots either covered with ornamental paper or placed in silver vessels, the stars are placed beneath these.

Apart from the ordinary upright flower-stands which have been described, we have a number of small glass baskets, each about the size of a tea-saucer but deeper, and having a twisted handle. The bowl of the basket rests on globular knobs, and beneath it is placed a prepared circular mirror-stand 16 or 17 inches in diameter, separate from the basket, and having a bordering of crimson chenille. These little baskets when filled, not crowded, with flowers, can be placed anywhere, and in my opinion look better than the taller ones, and are as useful for the drawing-room table as for the dinner-table. On the latter they can be introduced to fill up any spare place that may be desirable. They are made of ordinary white glass, all plain excepting the handle, and its presence amongst the flowers, &c., is pleasing.—J. Robson.

VERBENA CUTTINGS FAILING.

For two years my Verbenas have been suffering from the same cause as "R. F." mentions, and particularly Purple King. The cuttings when inserted in the autumn were not quite so good as I should have liked, still they struck readily enough, but after the first pinching that I gave them they began to look worse, and gradually died down from the point to the root, till I am now almost out of stock to propagate from. Last year it was Géant des Batailles that suffered most.

On seeing Verbena cuttings were gradually going off I have often thought over the subject, and I have come to the conclusion that the chief cause is that the stock is worn out. The

place where I am is far from any other garden, and I have to depend altogether on my own stock. I believe the stock of Purple King has not been changed for many years, and the same remark applies to Géant des Batailles. Last year I begged a few cuttings of the latter, and the plants from these grew much better all summer than any of the others, furnishing good cuttings in the autumn, and not one of them has gone off throughout the winter, all being treated alike. The other kinds which I grow have all been from fresh stock procured within a few years, and I cannot complain much of them, but even with them I find those which have been here the longest are the most difficult to obtain good cuttings from, and to keep all winter. I intend to obtain a few fresh plants of Purple King and watch them, and, if you think proper, I will report the result next year.

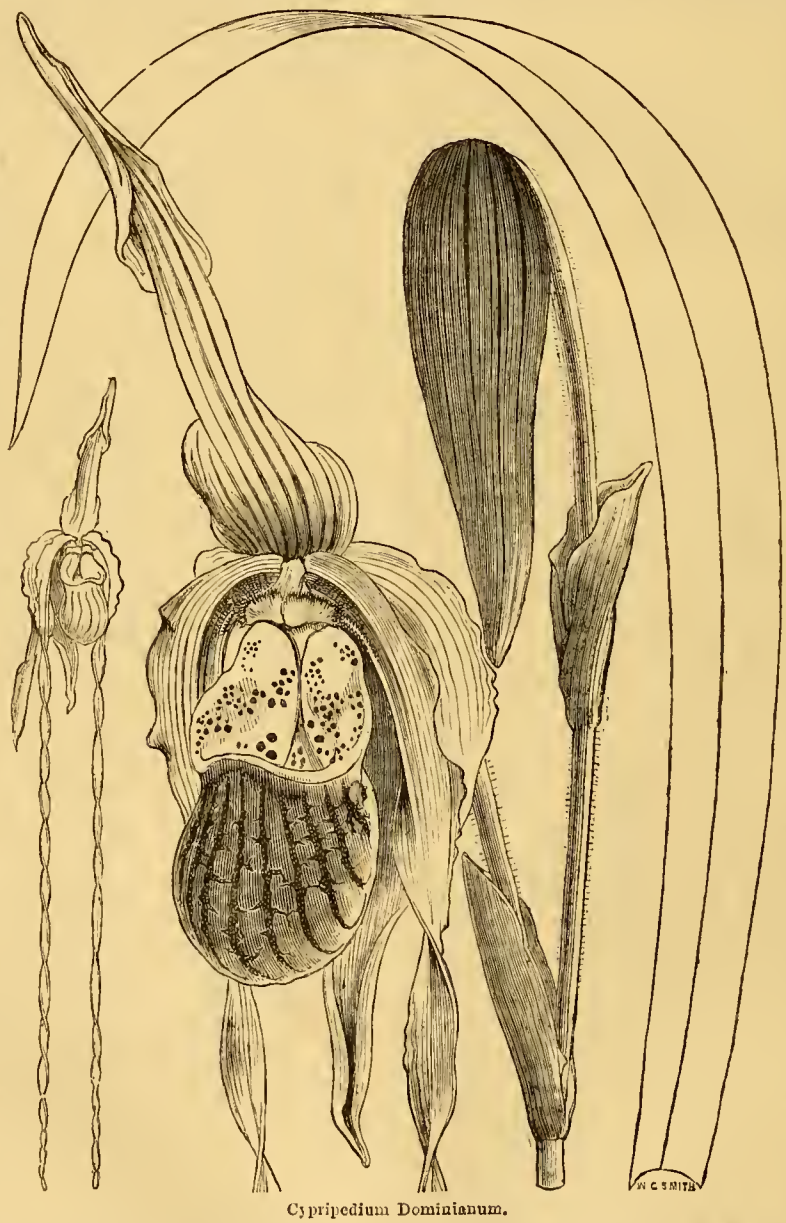
I think that it is desirable to change the stock sometimes, particularly when the same few beds have to be planted year after year, with just the addition of a little light manure perhaps. I hope some of your readers will observe the results of changing their stock, and report their experience.—S. N.

[We advised a change of cuttings years ago, and it would be more practised if gardeners could do so without endless explanations to employers.—Eds.]

CYPRIPEDIUM DOMINIANUM.

This beautiful variety is deservedly named after Mr. Dominy, so well known as the successful cross-breeder of Orchids at Messrs. Veitch's. Mr. Dominy obtained it by crossing C. Pearcei and C. caudatum.

The chief points in his own description of this offspring are as follows:—Peduncle many-flowered; spathe-like bracts half the length of the ovary; ovary rather pilose; sepals oblong triangular; petals caudate, ciliated; lip saccate, near the mouth retuse. It is remarkable that it is in almost every feature an intermediate of its two parents. Its flowers have the yellowish-green tint and purple veins and blotches of caudatum, and like them open all together. Messrs. Veitch find that it is a very free-growing variety.



Cypripedium Dominianum.

High March Temperatures.—So early in March the following high temperatures registered here may prove of interest. The thermometers have been verified at the Greenwich Observatory.

Day. March.	Max. in shade at 4 feet.	Max. in sun at 4 feet.†
2nd	58.4°	106.8°
3rd	65.4°	112.0°
4th	65.0°	112.3°
5th	57.2°	113.5°

—Francis Nunes, *Chislehurst, Kent.*

WATER SUPPLY.

I find that we have not here done half enough to insure the requisite supply of moisture in summer. There have been many showers, and many drizzling days, but here (near Luton) we have not had enough of moisture to penetrate far into the subsoil. Without a much greater rainfall I fear that next summer we must not depend on the moisture beneath. There are few places where thousands of gallons of water have not run to waste. With a continuance of such summers as we have lately experienced, a large reservoir of water will be indispensable both for the farm and garden, and the first expense of forming one will be true economy in the end. From a single broad piece of gravel I found that the water ran off it into a drain during a heavy rain at the rate of a gallon per minute. How valuable that water would have been in July! From all I can learn, the water in deep wells is getting very low, and is likely to be lower still.

Those who have a water supply at command know nothing of the ceaseless anxiety many of us endured last summer, when the great consideration was with how little water we could manage to keep plants alive. Even for damping paths, &c., in houses I was glad to use dirty water, knowing that there would be no sediment in the vapour given off. Contrast such a state of affairs with that of the gardener who, by turning a tap and hose, can water any part of his ground. No doubt there has been much injudicious and over-watering, but that is a very different affair from not being able to water at all. Without mulching and shading last summer many gardeners would have been quite unable to furnish a regular kitchen supply, and I only hope that in the ensuing season we shall have more moisture in the ground to fall back upon, if not larger reservoirs.

If I were entering on a large fresh place, where many pot plants, &c., were expected to be grown, I would, as a matter of first importance, make careful inquiries as to the water supply, and this is of still greater interest to a young gardener entering on his first place. I fear that it is something incidental to humanity to make some allow-

† Black bulb vacuum thermometer.

ance for shortcomings when there is a seen cause of failure, but to forget all about the consequences when these causes cease to be so conspicuously perceptible. I know that in many cases when the refreshing showers of last autumn came it was expected that the usual results in autumn produce would be forthcoming, altogether ignoring the dryness and the want of water power in summer. There are plenty of employers who will sympathise with the gardener in the loss of Cabbages and Broccoli from frost, but they will be apt to forget the frost in the fine sunny days of April and May, and perhaps grumble over the want of the accustomed supply. No gardener can at once make up the deficiency, but if wise he will try every means to let it be felt as little as possible. Of one thing he may rest assured, that when fine weather comes the effects of the frost will be little considered. The fine-weather produce will be eagerly looked for, and he must try by every means not to allow wants to be felt.—R. F.

NOTES AND GLEANINGS.

The public will hail with satisfaction the appointment of Mr. Gibson as the Superintendent of Hyde Park and Kensington Gardens, in both of which, and especially the latter, there is much room for the exercise of Mr. Gibson's well-known taste in garden design and his skill as a cultivator. His new position will afford a fresh field and a greater scope than Battersea Park, which has rendered his name world-famous. The superintendence of Battersea Park, we understand, falls to Mr. Roger, late of Berry Hill, Maidenhead, and that of Victoria Park to Mr. Macintyre, formerly of Kew.

WORK FOR THE WEEK.

KITCHEN GARDEN.

As the land becomes dry turn back with the fork the plot intended for *Carrots*, that it may become pulverised and open before sowing. The most profitable Carrots for small families are the Scarlet Short Horn and the Short Orange; a few of the Long Red may be added, as they keep somewhat better. Prepare a sheltered border for sowing a small crop of *Cauliflowers*, *Cabbages*, *Brussels Sprouts*, *Savoys*, and *Leeks*. To have the Leeks fine, sow under glass in a little heat, and afterwards prick out. Also, as the ground becomes dry, turn back with a fork the plot intended for *Onions*, preparatory to sowing as previously advised. The most useful kinds of Onions for general purposes are the White Spanish or Portugal, Strasburg, or White Globe, with a few of James's Keeping for late use. Underground Onions are useful for affording bulbs till the general crop is ready, and the true Silverskin for pickling. The autumn-sown plants should now be transferred to a warm rich border to furnish an early supply, likewise a few of the smallest bulbs of last year for the same purpose. *Parsley* and *Winter Spinach* will be much improved by a dressing of soot on the first wet day. Protect the crowns of *Rhubarb*, particularly the early kinds, by straw placed over them. *Sea-kale* in the open ground should be earthed-up to blanch. When the soil is sandy and light it may serve, but should be broken down fine before placing it over the crowns, that the heads may not grow crooked. On heavy soils old tan, decayed leaves, or coal ashes are useful substitutes for blanching.

FRUIT GARDEN.

Presuming that the pruning, training, &c., of trees and fruit bushes is now complete and the ground properly forked over between them, attention should be directed to the Strawberry plantations, which generally appear to have suffered severely. The beds should be cleared of weeds, and a dressing of rotten manure spread between the rows; it may afterwards be forked in very lightly, so as not to injure the roots. In doing this spread a little soil up to the crowns of the plants; doing so will assist the growth of new surface roots. Last season's runners should be gone over, and those which have been thrown out by the action of the frost should be made firm in the soil. Afterwards mulch the surface. Last season's leaves, although turned brown, should remain on the old plants for some time, in order to protect the new growth from cutting winds and frost. Apricots, Peaches, &c., if not previously covered, should have the protecting material put on, quite as much for the present to retard the opening of the flowers as afterwards to protect them from frost. The longer the opening of the flowers can be kept back the greater the chance of a crop.

FLOWER GARDEN.

The mixed or picturesque styles of gardening being those most generally adopted in places of moderate extent and for situations where a more formal style would not harmonise with other objects, herbaceous plants should always form a principal feature in gardens of the above description, and especially where the proprietor is resident the greater part of the year. To those who have hitherto grown only the usual bedding-out plants and annuals, and who have to wait till midsummer for a display of flowers, it is recommended that they procure a selection of the more showy Delphiniums, Campanulas, Phloxes, Dianthuses, and other ornamental herbaceous plants, Liliums, &c.; for planting among shrubs in borders, and for mixed beds, they are invaluable, while the fact of their affording a succession of bloom from early spring almost to Christmas ought to obtain for them a more general introduction, particularly where cut flowers and a continuous show of blossom are essential. The improvement in habit and colour which is annually taking place in the above and other genera of herbaceous plants is an additional inducement for growing them. A few annuals, including German Ten-week Stocks, may be sown in pots thinly for transplanting in the open borders in April for an early bloom, more especially as many autumn-sown annuals will have perished. Any Anemones yet remaining out of the ground should be planted, and the same direction will serve for any other bulbs yet unplanted.

GREENHOUSE AND CONSERVATORY.

The earliest started hybrid Rhododendrons and Azaleas, if now opening their flowers, should be placed in the conservatory, where they will add much towards making the house more than usually gay by the large masses of colour which good specimens of these showy plants present. During the period of blossom they must not be allowed to suffer from want of water, as the flowers always droop when such is the case. To make room for the above and other forced plants, any Camellias in pots which are going out of bloom may be removed to a cool house to rest. Keep up a supply of the various kinds of Roses, Lilacs, Weigelas, and the general stock of forced shrubs and bulbous plants. Those useful spring-flowering plants are equally valuable for cut flowers as for show. In addition, do not forget to have a large share of scented plants, as forced Sweet Briar, Aloysia citriodora, Oranges, Daphnes, Mignonette, and Violets, plants which are always in request. The weather having become milder, fire heat may be dispensed with for hardwooded greenhouse plants, unless the night temperature falls below 35°. At this time, however, and for a few weeks, let the necessary waterings and cleaning be done sufficiently early in the day for the air of the house to become dry before evening, when less danger will arise to the plants by a low night temperature than when they are exposed to it surrounded by a damp atmosphere. Pelargoniums, Calceolarias, and similar plants of soft growth should be kept in a night temperature of 45°, which may be increased a few degrees if the plants are wanted to bloom early. Keep them near the glass, and at a sufficient distance apart to admit the light freely to their lower leaves, which otherwise will turn sickly and fall off.

STOVE.

Stove plants which have been pruned-in and have made a few inches of new wood should be potted. Large specimens of Clerodendrons, Allamandas, Vincas, &c., should be partly shaken out and moderately disrooted. After potting plunge in a mild bottom heat, and syringe frequently to promote a healthy growth. Water must only be moderately supplied to recently potted plants until they become established. Let the night temperature be 65°, with an increase of from 10° to 15° on bright days. Although the shifting and fresh dressing of the general stock of Orchids will in most cases be completed, yet when the stock is extensive and contains a number of duplicates they should not all be started at the same time, as it is more desirable to have a succession of plants for blooming than a glut at one season, unless special reasons sanction a contrary practice. As this tribe is now mostly commencing growth, a gradual increase of temperature, accompanied with atmospheric moisture, should take place to encourage the utmost development of the present season's growth. Care must be taken that at this critical period of their growth the young shoots are neither rotted off by water being allowed to lodge round them, nor destroyed by slugs or insects. The latter should be trapped, and a nightly examination be made by candlelight for the former till a riddance be effected.—W. Keane.

DOINGS OF THE LAST WEEK.

Another glorious week—enough to make the heart of the seed-sower rejoice, for never did we see ground in better condition for sowing. We had the March dust even before March

came, let us hope we shall see something of April showers, for in this district water is anything but abundant, and thoughtful people are beginning in earnest to see the importance of not allowing the rains that fall on buildings to run to waste as formerly.

Such a season as this presents us with a vivid contrast as to the labours and cares of the farmer and the gardener. The farmer, when he has all his main seed crops transferred to the soil, can take a little repose; but, even in such fine weather as this, the gardener can sow only a small part of what he must have as produce during the season. With him, except as regards root crops, the question is less how to bring a number of crops to maturity than to have a number of succession crops, fit to be consumed in a juicy, succulent state, and therefore, however anxious, he can take but comparatively little advantage of the fine weather, so far as sowing is concerned.

KITCHEN GARDEN.

We have sown Parsnips, and a portion of Onions and Carrots, and will sow more Onions in the course of a week, as well as more Carrots at intervals of several weeks. For giving satisfaction with rich crisp Carrots, it is advisable to sow frequently until the middle and end of May, and even later. The worm seldom attacks Carrots whilst they are young, and even if they are not so large, they are very sweet and nice from late sowings, and suit admirably for being cooked whole. Parsnip being a very hardy seed can scarcely be sown too soon, if the ground is mellow, dry, and nicely pulverised. Beetroot, Salsafy, and Scorzonera we defer sowing for a few weeks longer, as there is a risk of their showing a seed stem when sown early. For all these root crops the ground should be well moved by trenching, ridging, and re-ridging if it is stiff; and to obtain fine, straight, clean roots, the manure given to such ground should be placed at the bottom of the trench to entice the roots downwards, and hence the surface soil should be poor rather than rich. With such care, even in old rich kitchen gardens, fine roots can be obtained by having these crops following a rather exhausting crop of the Cabbage tribe or Peas. We have sometimes had such roots after Celery, but whether the Celery was in rows or beds, the dung of the trenches, however equally distributed, was apt, from getting mingled with the surface staple, to encourage surface-rooting too much, and hence we are liable to have forked, branched, and crooked roots instead of clear, handsome, straight ones.

In all old gardens, with a superabundance of organic matter in the shape of manure, and which is apt to become sour and inert, nothing will be of such service as a dressing of quicklime incorporated with the soil. Even chalk in stiff soils will often be of great service as a lightener and regulator of moisture, but it will not act as a solvent like quicklime. In some cases it is quite surprising how a coating of an inch of lime will render a stiff soil porous and easily pulverised. It adds little or nothing, however, in the way of fertility to poor hungry soils, but even in them it acts beneficially by making them more retentive of moisture, whilst in stiff heavy ground the extra moisture, through its influence, passes off more freely. The most striking effect of a lime dressing is to be found on soil that may be said, from frequent cropping and manuring, to have become dung-sick; on such ground the effect is often very striking. With such a dressing the crops of Potatoes obtained in old kitchen gardens are often wonderful: hence lime acts most effectively on peat-mossy land, rendering the inert astringent vegetable matter soluble. On such ground we have seen extraordinary crops of Carrots.

We planted a good breadth of early Potatoes, placing them about 6 inches deep, as then, in common seasons, it is a matter of little importance whether they are earthed up or not. Last summer we wished we had earthed all ours up, as those earthed-up felt the effects of the dryness least, and ripened a heavy crop of fine tubers early. Those not earthed did not yield such fine tubers, the drought sooner reached the roots. In an ordinary favourable season we have found that Potatoes planted from 6 to more inches in depth yielded quite as good, and in some cases heavier crops than those that were earthed-up. Last season was so exceptional in its dryness that it is hardly appropriate to draw conclusions from it, except in the way of warning.

Plenty of air was given in the fine days to Potatoes, Radishes, Carrots, Lettuces, &c., in frames. Planted out a piece of early Potatoes in an earth pit, with hot leaves and manure beneath them, and some old sashes and other protection over them. Sowed Radishes between, as they will be ready to be off before the Potatoes shoot many inches. Our most forward Potatoes were planted in 9-inch pots, and placed in front of the Peach house until they were rather in the way and began to give signs of drawing a little, when they were removed to an earth pit, the pots being plunged an inch or two over the rims in a bed of old and new leaves that just yielded a mild heat, whilst the tops were protected with old sashes. These are tubering very nicely, and, as a general rule, early gatherings may be obtained more easily from pots than from Potatoes planted out in frames and pits.

We have a strong regard for *box frames* covered with sashes; they can be so easily moved, and turned to so many purposes, and when used for early Radishes, Carrots, and even Potatoes, they can be moved off as the spring advances, a more modest protection given, and the frames and glass used for other crops needing more heat. The brick pit cannot be moved. You may, in the same way as just stated, use the glass lights, but nothing more. Whilst loving the old frames in which even from early Cucumbers and Melons we have seen almost as great results obtained as by the best mode of heating by hot water—upon the whole, wherever there is game encouraged near the garden, and that game is fed when necessary, we should like entirely to substitute pits for frames, as mice and rats cannot so easily enter by the brick, and, if the wall-plates are sound, can hardly enter at all, except when the sashes are open. At one time when the wall-plates of even pits were worn out, it was not uncommon to find in the morning two or three runs made through the plate, and much mischief done by cutting things down in mere wantonness. When pits are resolved upon, it will be a great advantage to have them together, and in all cases where fuel is easily obtained, to furnish them with piping sufficient to keep out frost, as the fuel will rarely cost so much as covering, labour, and the breakage likely to be incurred. One evil, however, is very likely to ensue, and that is, if there is no hotbed of dung formed, the gardener may wish and wish over and over again for manure when he really wants it.

The Effects of the Winter.—We had a slight tour on business the other day, and where all vegetables as a rule were a week or ten days earlier than here, and, if such a thing could be possible, the wreck was more general; but in a few cottage gardens we found the Cabbages have stood, and in each case the plants were smaller and younger than ours. As already stated, our crops withstood the severest frost uninjured, but the damp, and fog, and comparative warmth between the two frosts did the injury. We were not aware that the temperature had been so low in this neighbourhood. Mr. John Fells, of Hitchen, told us that on one night with him the thermometer fell below zero of Fahrenheit for a couple of hours or so, and then it rose, and to that low temperature he traced the destruction among some of his finest shrubs. We forget now the hours of the night in which it was coldest with him, but we did not notice it so cold here at any time, and part of the mystery may have been that we did not notice the thermometer during these hours. We think, however, from all we have heard that the temperature varied much in different districts, and that in some cases it was the coldest in dry light soils, where we should have supposed it to be the warmest. On such light lands Laurustinus, Cupressus Lambertiana, &c., have been killed to the ground, whilst here they exhibit no trace of injury. In one place we saw the common Laurel as if the shoots had been exposed to a blast from a furnace, whilst here they are as green as if no frost had touched them. Singularly enough, in some places where shrubs have thus suffered the Cabbages have suffered far less than ours. Our expectations are so far realised, that in the light-land market gardens about Sandy and Biggleswade the young Cabbage plants have stood comparatively uninjured, and all the better the smaller the plants were. As remarked some time ago, the thoughtful gardener must use every means to bring up his leeway, as when the fine weather in May comes on the frost and its disasters will be apt to be forgotten.

FRUIT GARDEN.

We have not yet limewashed any of our dwarf fruit trees, but we fear we shall have to do so, as though the short hard-billed birds are less numerous than last year, they have made their mark on some of the most forward buds. Potted off Melon and Cucumber plants a second time, as we have no place ready for them as yet, and little is lost by having strong plants when turned out. A few Cucumbers are still to be had from some old plants in a small pit, and the young plants in large pots will soon take their place. No weather could be more favourable to them after the dull weeks and months. In all

such sudden changes from dulness to brightness, a little shading for an hour or two is often more beneficial than watering when the roots are moist enough. The plants should never flag, but in such sudden extremes from cloud to bright sunshine the leaves cannot at once, though there may be moisture enough at the roots, get the requisite amount of liquid to meet the greatly increased evaporation. A slight syringing to arrest evaporation will often be better than shading. We have even sprinkled the outside of the sashes with clean water, as before that was evaporated the rays of the sun did not pass freely. It is always advisable never to allow a leaf to flag, whatever mode be used to prevent it. The great evil of shading is not so much shading when necessary by any simple mode, as that the putter-on is apt to allow the shading to remain too long. Every minute it remains on when not wanted tends to make a plant weak, and to rob it of its natural robustness. Except for plants that naturally delight in the shade, the less shade they have, save in sudden extremes of dulness and brightness under glass, the better it will be for them.

Manure watering to everything in pots should also be given with discretion; it is seldom advisable to give it to flowering plants before the flower buds appear and the pots are well filled with roots; for such things as Strawberries in pots the flower trusa should show boldly. For Melons it is best to have the fruit set and swelling before manure water is given. There would be fewer errors on this subject if we could always recollect that brandy and fine old port are different things from small beer, however refreshing the latter may be. We once knew of some young Vines with roots near the surface of the border, and they never recovered after a copious watering taken from the cesspool of a large stable, and applied just as it came. The liquid was so strong that it would have stood well five or six times its bulk of common water, and then been strong enough for anything.

ORNAMENTAL DEPARTMENT.

There is still much planting, turfing, and alteration to perform in the pleasure ground, and for levelling and turf-laying no weather could be finer. If we should have a good rain in a short time all will be well, and the fresh turfing will never be distinguishable in summer. Where experienced layers of turf cannot be found much may be done by levelling well, and having the turf cut of uniform width and thickness. Many old lawns become uneven in the course of years, and taking them up, fresh levelling, and relaying, besides other advantages, are next to a death blow to the most staring broad-leaved weeds.

A short time ago we noticed an inquiry as to the merits of a chemically prepared sand for eradicating all such broad-leaved *weeds on lawns*, as Daisies, Plantains, &c. We have forgotten for the present the maker's name. The great objection to the free use of the material was its price, except for a lawn of the smallest dimensions. We tried a little barrel of it, and found that when freely applied all such leaves first became black, then shrivelled up and disappeared, and the roots of Plantains were killed to their extremities. Smaller doses killed the leaves and part of the root-stems, but in a month or two small stems came again from the bottom of the root. What seemed to us, however, the most incredible part of the statement of the maker and vendor was, that this sand powder would do no injury to, but rather improve, the common grasses of our lawns; but we found this statement perfectly correct, inasmuch as whilst it blackened and shrivelled up Plantains, &c., it did no injury to the common grasses. On the whole, on the score of economy, we satisfied ourselves that it would be cheaper to grub up Plantains, &c., to the extremities of the roots than to use the prepared sand. But there are many who would like to get rid of the weeds without disturbing their lawns, and if any of our readers have tried the remedy we should be glad to hear the results. We regret forgetting the maker's name, but we have no doubt he has discovered the means of at least temporarily putting Plantains and other large-leaved plants on a lawn out of sight without injuring the grass of the lawn. More decided effectiveness may yet be combined with more economy.

Forward bulbs out of doors will require a little protection from frost and heavy rains if these come. We find great difficulty in keeping such bulbs as Crocuses without being well protected. We have even had the shoots cut over after showing flower. We are almost inclined to give way to envy when we see lines and combinations of Crocuses without a seeming break in the whole, as if the mice disdained to touch them. We may trap by scores, but still the corms of the Crocuses are eaten up. We have thought of several modes of doctoring the corms; but then that would be of no avail as a preventive against having the shoots cut over and mangled when above ground and showing bloom.

We took the opportunity of turning up empty flower beds and leaving them rough, as we prefer what manure we give to be chiefly confined near the surface, to encourage early rooting after planting.

Violets are now coming plentifully in the open air. Our Czar protected with glass has been very fine. Our Neapolitans this year have not been up to the mark during the winter, though showing well now. The reason is, that owing to the dryness of the summer, and our inability to water them, the plants suffered much from red spider. We kept them alive by shading them with evergreen boughs, but the shading helped to weaken them. We trust that they will all be secure next season, as though we may be prejudiced, we still think a fine, large, Neapolitan Violet the king of Violets. For making-up, nothing equals the Czar, owing to the long footstalks or flower stems, as well as the size of the flowers. We have not had an opportunity of seeing some new and different-coloured Violets, single and double, and inquiries have been made about them which we could not answer. We should be glad if correspondents would state the results of their experience, and more especially if there is any white, pink, or reddish variety, either single or double, that for general utility will equal the Czar. We have had some good gatherings of this kind from our open border towards the end of February, and now it is beginning to show from a row at the base of the north side of a wall. We put it there hoping to have it later than in the open ground, and we shall continue this practice. No plant is more easily multiplied, for, not to speak of runners, a small plant of last May may be divided into a good number as soon as it has done blooming. Like other Violets, it is improved by dividing and moving. It should not bloom more than two seasons in one place. We rather think it does best when planted every year, as a small plant in April or May becomes a strong plant before the autumn, if there are showers in the summer.

Much work has been done in potting, cutting-striking, &c., and the great object now is to find room and conveniences for the plants required, without injuring general crops. Many of us must put every house to a number of purposes. Potted-off a good batch of the brown and other Coleuses, Iresines, &c., but must top them several times to obtain the number required. With a little bottom heat, however, such plants strike and grow very fast. Speed will also be obtained by potting all such tender plants in a warm place, using warmed water, and well-aired warm soil. The less check a plant or a cutting has the better, and the more likely will a healthy growth and freedom from insects be secured. The great secret of striking cuttings is to secure the cutting feeling as little as possible its severance from the parent plant. When we see cuttings from a warm place lying wilted and flagging in a shed, or left in a cold place after being inserted, we often wish that the cuttings had a voice, and used it in remonstrance.—R. F.

TRADE CATALOGUE RECEIVED.

F. & A. Dickson & Sons, 106, Eastgate Street, and Upton Nurseries, Chester.—*Catalogue of Farm Seeds.*

TO CORRESPONDENTS.

*** We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By doing so they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

ROYAL HORTICULTURAL SOCIETY'S EXHIBITIONS (*Pomona*).—If you write to J. Richards, Esq., Assistant Secretary, Royal Horticultural Society, South Kensington, he will send you full printed particulars.

VINE MANUAL (*R. Whitaker*).—No new edition is about to be issued, as such is not required. It is the "Fruit Manual" which is in preparation.

DINNER-TABLE DECORATION (*H. C.*).—We shall readily receive your notes.

Most Productive Fruit Trees (*J. C.*).—How could any opinion be given without the slightest information as to soil, elevation, locality, whether for kitchen or dessert, and whether early or late varieties are needed?

Grass Seeds Sowing (*W. B. B.*).—The beginning of April is the most suitable time to sow Grass seeds, taking advantage of weather in which there is an early prospect of rain.

Seeds (*A. B. C.*).—Messrs. Wrench & Son, Seedsmen, King William Street, London, E.C., can inform you.

Planting Pear Trees (*A Subscriber*).—We can hardly give an opinion as to your probable ultimate success. The precautions you have taken for preventing the roots getting into the subsoil are so far good, if sufficient. They may induce the roots to spread nearer the surface, although they may not absolutely prevent their descending. We recommend you to examine the roots frequently and arrest any that may have a downward tendency.

Hyacinths for the 12th February (*Jacob*).—For flowering by the time you name the bulbs should be potted at the end of September or early in October, and should be kept plunged in coal ashes in a cold frame. At the close of November they should be placed in a house with a temperature of from 40° to 45°, and be continued there until the end of December, when they should be placed in a light airy position in a house with a temperature of from 45° to 50°, and in a fortnight they should have a temperature of 50° to 55°. When in flower they should be moved to a cooler house. They will flower finely at the time you require. You will find the properties of the Hyacinth fully given in "Florists' Flowers for the Many." It may be had post free from our office if you enclose five postage stamps with your address.

Begonia Plants Going off (*A Young Gardener*).—The cause of the plants going off, we should say, is the late sowing of the seed, and consequent small growth made before winter, and the "plenty of water" would only assist their going off. Lessen the supply of water, not giving any until the soil becomes dry, and then enough to show itself at the drainage. This is a good time to sow the seed, but we should not hesitate to sow all but the herbaceous kinds when ripe. The latter are best sown in spring.

Cucumber and Melon Pits (*Yeoman*).—Where there is no fear of water, or a drain can be laid to carry off any water that may run towards the pit, the excavation may be 2 feet 6 inches deep, and along the back and front you will require a space of 2 feet for linings of hot dung—that is, if you contemplate forcing early, but if you intend to use it only in summer, then the linings may be dispensed with. The walls of the pit should be pigeon-holed up to the ground level, or 2 feet 6 inches high in front, and 3 feet 6 inches at back. The inner walls, or those of the pit, need not be more than half a brick (4½ inches) thick, and above the pigeon-holes they should be built solid. The sides of the excavation will need brickwork a brick thick to keep up the soil, and should be carried-up level with the ground, and then have a course of well-burnt bricks set on edge. The height of the front wall should be 4 feet, and of the back 6 feet. You will need a partition to divide the part intended for Cucumbers from that proposed for Melons. A 4½-inch wall answers very well. Cox's Volunteer is a good Cucumber of easy culture, Telegraph is also excellent, and so is Masters's Prolific, a not-large but very free-bearing sort. Of Melons, Heckfield Hybrid and Beechwood are good green-fleshed sorts, and Malvern Hall and Pine Apple (Wills), are fine, free-setting, scarlet-fleshed kinds.

Fruit Trees Newly Planted (*Q. Q.*).—No practice is so bad as cutting newly-planted fruit trees to skeletons. Do not shorten any of the shoots of the wall trees except the central shoots, which should be pruned-in to 12 or 13 inches. The short stubby shoots leave entire, if not of greater length than a few inches, and all the terminal shoots train-in at full length. Of course, you will need to cut back all side shoots not intended to form principal branches to within half or three-quarters of an inch of their base, but leaving the spurs entire. It will hardly be necessary to water this month, but if the weather be very dry water may be given, though we have not found it necessary in a quarter of a century's practice. If the soil be moist it is all they require. The Vines planted in hampers and placed in a friend's greenhouse, with canes 6 feet long, will need to be pruned to the length required to reach from the ground to the wires of the proposed vinery; but as the time is gone by for pruning, we would as they swell rub off the eyes to the height you require, and when there are leaves you can cut away the disbudded part. In planting remove the woodwork of the hampers, for if buried we are not certain that it would not breed fungus injurious to the Vines.

Fruit-room Construction (*A. M.*).—The site of a fruit-room should be low rather than elevated, as when it is somewhat below the ground level there will be less fluctuation of temperature. It is necessary, however, that the site should be dry, and if not it must be elevated so as to guard against damp; the floor should be concreted, and the foundations of the walls ought to be asphalted, so as to prevent damp from rising. It is well to plaster the walls with cement. A north aspect is most suitable, and next to that east; a south or south-west aspect is the worst of all. It is very important to maintain an equable temperature, and the best means of securing it is double walls having a cavity of about 3 inches. Confined air is the best non-conductor of heat, and applies equally to cold and damp. The roof should be double-ceiled, with a cavity between. The most suitable temperature is 40°, and not exceeding 50°. Provision should be made for ventilation to dry-up any superfluous moisture, and especially in autumn, when the fruit is housed in quantity; therefore, means of giving thorough ventilation should be provided for, and the power to close should be equally effective. The ventilation should be provided in the highest part of the room, as it then admits of a freer circulation of air. Light will be necessary for operations in connection with the fruit, but at all other times the room must be quite dark. The windows must have close-fitting shutters, and, like the walls, should be double; in severe weather they should be covered with mats, and if they enclose hay and are placed on the outside they will better exclude cold. The atmosphere must not be dried by fire heat, and so long as the fruit is dry the room is not too damp. The means of affording artificial heat should be as far distant from the fruit as possible, and in no case beneath it. These are the main essentials of a fruit-room.

Fruit and Plant Houses Combined (*J. N.*).—In building such houses it is advisable to have them in two or three divisions, as thus you can have a succession of fruit and flowers. For early Grapes we prefer a lean-to house with a wall on the north side, sloping glass to face the south, and the slope not less steep than an angle of 45°. For general crop, and to contain plants for flowering and bedding, we would avoid the building of a high wall, and have a house from 16 to 24 feet in width, with a pathway down the centre, and a stage or platform at each side. Glass will be found cheaper than brick, but for early work more heating will be required for a span than for a lean-to roof, the wall at back acting both as a protection and a reservoir of warmth. Such a house could have its ends due north and south, the north end of brick, the south end of glass. This would answer very well, but instead of due north and south we would prefer the ends to be a little north-east and south-west. We should thus obtain the greatest possible amount of sun. There is a great advantage in such span roofed houses thus placed—that the midday sun strikes the roof obliquely, and the greatest heat will be obtained respectively on the east and west slopes. According to circumstances the decision must be made. A low wall on each side would do for a steep span roof, and the bottom ventilation could be given in the wall, and the top by double-ridge board and cowl, so that all the roof could be fixed on the orchard-house principle, or easily moved on the Beard or the groove principle. As stated above, if lean-to, the houses should face the south; if span-roofed the slopes should more or less face due east and west. We would advise that the Vines be planted inside in either case; but if a wide-span house we would have a border inside and outside too if convenient. The simplest mode of doing so is to build the front wall on arches or piers. The latter would answer very well with a stone or iron sill if you had front lights for ventilation. If the ventilation is to be in the wall, then an arched wall would be best.

Briar Tops Covering—Roses Pruning (*T. G.*).—The tops of the Briars should be pruned smooth, and may be brushed over with patent knotting, such as painters use. We consider the end of February not too early to prune Roses, but for a late bloom pruning may be advantageously done at the commencement of March.

Box for Edgings (*J. J.*).—Now is a good time to put in cuttings of Box, slipping off the pieces, and inserting them with 1 or 2 inches of the top out of the soil. The top should not be pruned; merely remove any irregularities of growth. Many evergreen shrubs may be propagated in the same way; but the best time to put them in is at the end of summer when the growth is complete, say the end of September. Water the Box if the weather be dry after planting, and afterwards in dry weather until it is growing freely.

Selections of Plants for North Wall, &c. (*H. S. N.*).—*Six Climbers for a north wall* are Ampelopsis hederacea, Hedera hibernica (canariensis of some), H. Rægneriana, H. Helix foliis variegatis, H. Helix aurea, and Cotoneaster microphylla. Ivies are the most suitable subjects for a north wall. *Twenty-four Hybrid Perpetual Roses* may be Achille Gonod, Alfred Colomb, Baronne Prevost, Camille Bernardin, Caroline de Sansal, Charles Lefebvre, Comte de Nanteuil, Dr. Andry, Duc de Rohan, Elie Morel, Gloire de Santenay, John Hopper, Lady Suffield, Louise Peyronny, Madame la Baronne de Rothschild, Madame Victor Verdier, Maréchal Vaillant, Paul Verdier, Pierre Notting, Princess Mary of Cambridge, Senateur Vaisse, Vainqueur de Goliath, Victor Verdier, and William Griffiths. *Six Golden Tricolor Pelargoniums*—Achievement, Lucy Grieve, Sunray, Jetty Lacy, Lady Cullum, and Miss Watson *Six Golden and Bronze*—Edward George Henderson, Egyptian Queen, Fascination, Masterpiece, President, and Trojan. *Six Silver Tricolors*—Mrs. John Clutton, Excellent, May Queen, Picturata, Italia Unita, and Cherub. *Six Vines for a cold house*—Buckland Sweetwater, Black Hamburgh, Black Champion, Trentham Black, Foster's White Seedling, and General della Marmora. *Twelve shrubs for an east aspect*—Aucuba japonica, Berberis Aquifolium, common and Portugal Laurel, tree Box of sorts, Hollies, Cotoneaster Simmondsii, Philadelphus coronarius, Ribes sanguineum, Lilacs, Sambucus racemosa, and Skimmia japonica.

Arrangement of Houses (*R. T. G.*).—There can be no objection to the proposed arrangement as it is given, and no doubt the propagating pit would be useful. In either case you might plant Vines at the back of the vinery, but if the hipped roof were contrived to form the span of the same slope as the other side, there would be more room for the Vines. The Vines against the back wall will not succeed there unless the glass roof be but moderately covered. They will fruit well when they reach the glass. We have seen Vines do admirably when planted thus on the north side, and trained down the glass in a lean-to house. We prefer that a span-roofed house for a vinery should have its sides east and west, and its ends north and south.

Planting and Pruning Young Vines (*A Subscriber*).—If you are afraid that the young Vines would bleed if pruned back to the necessary length now, we would let them alone, but as soon as the buds lengthen, say half an inch or so, you may rub off all you do not want, but you must not cut them off; that will cause bleeding, but the rubbing off with the thumb and finger will not. When the Vines have started and made a foot of young wood, you may prune back safely as you propose, but by that mode you will be apt to check the Vine more, and lose so much more for the main shoot, than by the above mode of rubbing off the started buds.

Forcing Strawberries (*Fifteen-years Subscriber*).—To succeed in forcing Strawberries well, the following simple matters will have to be attended to, and, for the sake of simplicity, we shall confine ourselves to one mode. First, as soon as you can obtain runners, however small, from a fruitful Strawberry plant, place the runner with its incipient roots in a small pot (60-sized), with a pebble in it to keep the runner in the rich light soil. Water frequently until the pot is full of roots. When it is so filled cut the runner, take away the plants in the pots, and let them stand in a shady place for a few days. Then shift these well-rooted plants into 5 or 6-inch pots, using rich stiff soil, and keeping the bud of the plant nearly level with the rim of the pot. Make the soil all round the ball as hard as you well can with fingers and a stick. Most likely the pots will need a little shade for a few days after potting, but after that the plants cannot have too much sun, and the pots should stand on a hard bottom. When the pots become crammed with roots use manure water of various kinds freely, provided it is not too strong, for too strong doses are to be avoided. As autumn advances let the plants have all the sun possible, but diminish watering that the buds may be well ripened. In winter, if the pots can be protected from frost, snow, and excessive rains, it will all be in favour of the plants. In cold places in the north it is often advisable to prick out small runners, let them have a summer's growth, and take them up next summer and pot for forcing.

Wireworms (*T. Mayes*).—It is very difficult to eradicate wireworms when they find their way in such abundance into an orchard house. We are of opinion that the modes suggested by you would greatly reduce, if not exterminate, the enemy. Meanwhile, as the time has gone on and nothing has been done, we should be inclined to give a good watering with guano, or with soot water, which would make the wireworms a little uncomfortable, and then insert all over sliced Carrots, and examine the baits every day.

Buckwheat (*J. Bell*).—Sow in April; three pecks will be enough seed for your half acre if you drill it in; keep it hoed. No special culture is needed, and on rich land it runs too much to stem. It succeeds even in Russia. The seed will be ripe by the end of October. Pull up the plants, for the seed sheds very readily.

Ants (*A. C.*).—Soak their haunts for a few days successively with ammoniacal liquor from the gas works. "The Poultry Book for the Many" will suit you. You can have it free by post from our office if you enclose seven postage stamps with your address.

Plants for Cover in Boggy Soil (*P. C.*).—Few shrubs would succeed in boggy soil unless it could be drained. In this case you might grow Berberis Darwinii, B. repens, B. Aquifolium; Rhododendron ponticum, Aucuba, common Laurel, evergreen Privet, St. John's Wort, common Berberry, Black Thorn, common and red-berried Elder, Hazel, Ribes, Snowberry, Sweet Briar, and Pampas Grass. With the soil not drained you will find few shrubs will grow, but you may plant the Alder (Alnus glutinosa), the cut-leaved variety being very fine. Both the common Dogwood (Cornus mascula), and the red (C. sanguinea), do very well. C. mascula variegata has finely-variegated leaves. Guelder Rose (Viburnus Opulus), is also good, and especially V. Opulus nanum, also Deutzia scabra. To these may be added Willows; the American, Palm, Bedford, Cane, Norfolk, and common, Red, and Yellow Osier, are all good, and should be cut down frequently. Cover being the object, few things equal the common Sedges. They make excellent cover, and so do most of the Reeds. Of flowers, in the open spaces employ Caltha palustris and the double variety, Myosotis palustris, Water Iris, and the Epimediums, with other semi-aquatic plants, which you may, no doubt, find in your immediate locality.

Abutilon venosum Treatment (*B. B*).—That is the name of the plant of which you enclose a leaf and flower. It requires ordinary greenhouse treatment, and is a good plant for covering walls or trellises. A compost of two parts sandy fibrous loam, and one part leaf soil, with a liberal admixture of sharp sand and free drainage, will grow it well. Repot at once, and to secure shoots for covering the wall take out the points of the shoots to induce more branches. It should have a light airy position, otherwise it will not flower freely. It is very pretty, and well worth a place in every greenhouse. Water should be plentifully given when growing, but none should be supplied so long as the soil remains moist, but when it becomes dry, and before the foliage flags, give a good watering, sufficient to show itself at the drainage.

POULTRY, BEE, AND PIGEON CHRONICLE.

MANAGEMENT OF POULTRY AT SHOWS.

Had I the arrangement of any show my plan would be the following. I would arrange the regulations so that the latest time for admission of specimens should be dusk on the previous day. If birds arrived before, I would provide some means of thoroughly darkening the exhibition room. If this could be done thoroughly, specimens might be taken in at any time, as with scarcely any light the birds would remain passive on the bottom of the basket or pen, and allow themselves to be quietly handled. In handling fowls I believe the best way is to take the bird round the shoulders with both hands, the thumbs uppermost, keeping the wings from moving.

As to Geese, Turkeys, and Ducks, the last-named may be treated and handled as fowls. The two former, if the pens are on the ground, may, by a gradual and slow tilting of the hamper, be made to walk into the pen; but in these larger specimens the feathers are so much stouter and the plumage so much less easily injured, that there is not the same fear of mischief.

Much, very much, depends on whether a bird is accustomed to being handled, and it is wise for exhibitors to handle their specimens frequently, as they are thus rendered tamer.

One word more. It is far better that shows should close early on the last day, that the last meal for the birds should be bread soaked in ale or gravy, and that the specimens should be packed at once—if there is a night train, to be forwarded by it; if not, by the earliest in the morning.

I see at Northampton the committee promise that the birds shall be sent off the following morning "after being well fed." Now, if well fed means hard food, I would much sooner my birds were dispatched fasting, and I believe less injury would be done.—Y. B. A. Z.

HANDLING POULTRY.

If I were to take hold of a Game cock, I would put my right hand on his back and secure his wings. I should object to taking an old cock by the legs first, as his spurs are rather troublesome. I would secure the wings of all birds first, Geese and Turkeys not excepted. When you have a bird between your hands, then remove it from the hamper or pen, and there will be no fear of damage. I do not approve of taking hold of the head, and I hope neither does "R. D."—C. P.

ARE THE OFFICE-BEARERS OF A SOCIETY RESPONSIBLE FOR ITS DEBTS?

In the case of Mrs. Helen Grassick, Oriel Cottage, Edinburgh, against Mr. John Baillie, Treasurer of the Aberdeen Poultry Club and Pigeon Association, and against Wm. Grant, the Secretary, William Hay and James Anderson, Vice-Presidents of the Club, whereiu the pursuer sues the defenders for the sum of £2 12*s*., being the amount of four prizes gained by the pursuer for fowls belonging to and exhibited for competition by her at the exhibition and competition for poultry held by the said Association in December, 1869, the prizes being awarded to her by the Association, or their office-bearers, or officials, or judges. Sheriff Comrie Thomson has just given judgment. It will be remembered that Mrs. Grassick got a Small Debt decree in her favour for the amount against the Association, but, it being found that it was impracticable to put it in force against the Association, there being no funds, she raised this action in the ordinary Court against the defenders as office-bearers, the contention being that they were responsible for the debts of the Association. The Sheriff in his interlocutor finds that no relevant ground of liability by the defenders has been set forth in the summons, and therefore dismissed the action, holding the pursuer liable for expenses. In his note the Sheriff says—It was not averred that the Aberdeen Poultry or Pigeon Association was a mercantile copartnery carried on for the purpose of gaining profit. It was plainly of a different nature; and the Sheriff-Substitute was of opinion that the well-known rule of law that "each partner is responsible for the whole debts of a trading company" did not apply.

[The above is extracted from a Scotch newspaper, and we think Mrs. Grassick failed because she sued wrong parties. If she had had the usual correspondence, written or printed, with the Secretary or any other officer or member of the Committee, and had sued that correspondent in the Small Debt Court, we think she would have recovered the £2 12*s*. She did obtain a decree against "the Association," but the Sheriff's-Substitute rightly decided that such Association is not a sueable partnership.]

OUTRAGES ON PRIZE BIRDS.

I sent a valuable Black Red cock to Wolverhampton on the 2nd ult. He was seen there in perfect feather on the 4th, but although not noticed in the prize-list, some one evidently considered him a possible winner on some future occasion, for he was returned to me with both sickle feathers broken short, and one of the smaller sickles plucked out. I wrote to the Secretary requesting him to use every possible means for the discovery of the offender, and authorising him to offer a reward of £5 for information which would lead to a conviction, and received a reply, saying that he "is sorry to hear that the bird is injured," but "is certain it was not done there," and promising to "make every inquiry, and write me again." How Mr. Barnett happens to be able to speak so confidently of the injury not having been done at the Show I cannot understand. If this nuisance continue to increase, all respectable persons will cease to exhibit, and the poultry sharks will be left to mutilate each other's birds. Will some one take the matter up, and try to establish a fund for the purpose of offering a tempting reward for the detection of similar offenders?—Edwin Brough, *Leek*.

Our Journal has contained several communications on this very important subject. Since November I have suffered in this way rather seriously. To begin with the Southampton Show, I there exhibited a Malay cockerel in the Variety class, obtaining the second prize. Now, in this case the sickle feathers were not fully grown, and would, if untouched, have lasted till August or September next, and nothing but foul play would have removed wholly one of these feathers; yet on his return, one sickle feather was clean gone, root and branch. Then I sent a second Malay cockerel to Birmingham, where he was unnoticed; he had been twice exhibited by me before, taking the first prize at Whitworth and Rochdale, and the second prize at Middleton, and from both these shows he returned with tail undamaged. From Birmingham he returned with both sickle feathers broken off, one hanging, the other not to be found in the basket, which was lined, and the same in all three cases. Lastly, I exhibited at Bristol an old Malay cock, with sickle feathers scarcely yet at full growth after moult. He was at the head of the Any other Variety class, and he too has returned to me with both sickle feathers broken off.

Now, supposing all these misfortunes to be accidental, it is singular (perhaps I am hardly correct in writing this term in my case), but it is strange, that three cases should occur in the same small yard in three months. Possibly I am now going to touch on somewhat dangerous ground, but the conclusion is rather forced on me. Firstly, I would suggest to judges that their handling of specimens should be as little as possible, and that in most of the classes it is wholly unnecessary. I shall probably be hooted at as heterodox! Well, that will not hurt me, my opinion remains the same; but allowing that some amount of handling is necessary in awarding the prizes—that being over, all handling ought to cease, except by the owners themselves, or in their presence, or, as a matter of appeal, judicially by the committee. I have, however, seen a judge giving a perfect lecture on the intricacies of a breed to an exhibitor on the day when the exhibition was opened to the public, and taking out bird after bird in a manner which I confess I thought at the time too rough, and which with wild birds might easily produce the annoying accidents alluded to. Secondly, sticks should be left at the doors by visitors. Lastly, I think such accidents would often be avoided if all the packing and unpacking of the birds were performed with the light almost excluded from the building.

I am quite aware that our railway officials are not too careful over our specimens. I therefore always send mine in round hampers lined carefully.—J. Hinton, *Warminster*.

POULTRY KILLED BY A DOG.

As the law respecting the destruction of poultry by dogs does not seem to be generally known, the following may be interesting to many of your readers:—

"The general rule of law is that the owner of a dog is not liable for any injury committed by it to the person or to personal property, unless it can be shown that he previously had notice of the animal's mischievous propensity, or that the accident was attributable to some other neglect on his part." Fowls being personal property, it follows that a dog may enter a poultry-yard, and destroy any number of valuable fowls, and the owner of the fowls is without remedy against the owner of the dog, unless he can prove that the mischievous propensity of the dog was known to its owner, or that the latter has been guilty of some neglect.

Dogs chasing conies in a warren, game in a preserve, deer in a park, sheep in a fold, or fowls in a poultry-yard may be killed whilst in hot pursuit, but not afterwards.

A case, which clearly shows the injustice of this state of the law, was recently tried in the County Court at Stockton-on-Tees. A pointer dog, whilst being used in sporting, ran away from its master into a neighbouring town, where it roved about for some days. At length, being hungry, or from some other cause, it effected an entrance into a poultry-yard, and destroyed four very valuable Cochin fowls. The owner of the property sued the owner of the dog, and tried to show that the latter had been guilty of negligence in losing his dog, and allowing it to range about a town so long without food. The Judge, however, held that losing a dog was not such negligence as would render the owner liable, and nonsuited the plaintiff, with costs.—*

[We incline to the opinion that if the plantiff had sued for the dog's trespass he might have recovered.—Eds.]

BIRMINGHAM FLYING MUFFED TUMBLERS.

I think that I can solve the mystery of the origin of these Tumblers, professed by the Birmingham fanciere, or flyers of these Pigeons, to be unknown to them.

My conjecture is that the common Antwerp Pigeon, not the Antwerp Carrier, a grizzled or strawberry-feathered bird with pearl eyes and not unlike the Tumbler in form, is one ancestor in a cross with the European Tumbler as the other ancestor of these Pigeons, and improved by another and third ancestral cross with the English Tumbler for symmetrical specimens. Thus we have the Antwerp's powers of flight (notorious), the muffed leg of the European Tumbler, and the symmetry of the English Tumbler, more or less developed in these Birmingham Tumbler Pigeons. I found my conjecture upon the fact of the Antwerp, in Lancashire called "White Eye" from its wild white eye, being a superb flying bird over home. Indeed the Lancashire Pigeon-race flyers use a cross of the White Eye and Dragoon for their sport. But the pure White Eye is kept in crews for high flying, and soars into the clouds and flies in circles almost invisible for one, two, or three hours, over home consecutively. If confined too long without a fly, these White Eyes are apt (as did a crew the other day not half a dozen miles from me) to soar out of sight and disappear for ever—maybe go back, from some innate instinct, to the home of their fathers, the city of Antwerp, for, save a few stragglers, they are heard of no more. Such is the White Eye, the blood of which I surmise to be in the Tumblers under notice. Tumblers the Birmingham birds are and something more, being, I should say, Anglo-Hybrid-Antwerp Flying Tumblers, a designation they need not shame to own in their exemplification of the characteristics implied.

As matter appropriate to our subject I will relate an anecdote of the Antwerp Carrier Pigeon. A calico printer, who spent some time in Belgium, brought a few pairs of these birds to his home in England near Manchester, and kept them in confinement until they had bred him a young stock, for certainty, as he thought, of settling old and young birds safely. Conceive his surprise when, the first time the old birds rose into the air, they darted away regardless of the young birds behind, which alone remained, and, as he concluded, were lost. But lost they were not, for they flew home into Belgium, and this after a sojourn of twelve months and one breeding season in England!

The same person gave a pair of the young birds (the young birds I mentioned) to a friend, who transported them to his own loft, some twenty-five miles distant, and the first flight—they had never flown before—made by these young Antwerp Carriers was to the place of their birth, over several towns and a range of hills of no inconsiderable height. So is demonstrated the instinctive homing faculty of the Antwerp Carrier, for these very birds were not trained birds, and yet the old birds crossed a great part of England and the Channel into Belgium, and their young nestlings traversed twenty miles or more of inland route safely, the face of the earth in each instance being unknown to old and young birds alike.—Reader.

COLCHESTER POULTRY SHOW.

This took place on the 1st and 2nd inst., and consisted of nearly three hundred entries of poultry, and upwards of one hundred entries of Pigeons, besides Rabbits. The awards were as follows:—

Dorkings.—*Coloured.*—1, Henry Lingwood, Barking, Needham Market. 2, F. Parlett, Great Baddow. *hc*, Mrs. G. Meek, Balcombe; J. Norman; W. Tippler, Roxwell, Chelmsford; J. Frost; Mrs. G. Clarke, Long Sutton. *c*, J. Norman; J. Frost, Parham. *White.*—1 and 2, J. Robinson, Garstang. *c*, Rev. F. Tearle, Gazeley Vicarage, Newmarket.

Cochins.—*Cinnamon and Buff.*—1 and *c*, Henry Lingwood. 2, J. K. Fowler, Aylesbury. *Any other Variety.*—1, T. Sharpe, Ackworth, Pontefract (Partridge). 2, Horace Lingwood, Creeting, Needham Market (Partridge). *c*, J. H. Dawes, Moseley Hall, Birmingham; Horace Lingwood (Partridge).

Brahmas.—*Dark.*—1, Horace Lingwood. 2 and *c*, H. Dowsett, Pleshey, Chelmsford. *hc*, W. Burrows, Diss, Norfolk; Horace Lingwood. *Light.*—1, H. Dowsett. 2, Mrs. A. F. Barnett, Erdington.

Spanish.—1, Nichols & Howard, Camberwell. 2, F. James, Peckham Rye. *hc*, E. W. Shalford, Maidstone; W. Saunders, Lowestoft.

French (Any variety).—1, W. Burrows, Diss (La Flèche). 2, Mrs. J. Cross, Appleby Vicarage, Brigg (Crève-Cœur) *hc*, W. Boutcher, Notting Hill (Crève-Cœur); Mrs. E. Williams, Henllys, Berriew (Crève-Cœur); W. Tipoler (Houdans and Crevecœur); W. Dring, Faversham (Crève-Cœur). *c*, J. K. Fowler; A. H. Paley, Dedham (Houdan); W. Dring (Houdans).

Game.—*Black-breasted and other Reds.*—1 and 2, S. Matthew, Stowmarket. *c*, G. Barton, Wymondham; H. F. Martin, Sculthorpe, Fakenham; R. Hull. *Duckwing and other Greys and Blues.*—1 and 2, S. Matthew. *c*, J. H. Salter, Tolleshunt D'Arcy, Kelvedon. *Any other Variety.*—1 and 2, S. Matthew (Piles). *hc*, J. H. Salter (Piles). *c*, J. J. Hazel, Great Bromley, Manningtree.

Hamburghs.—*Gold-spangled.*—1, L. Wren, Lowestoft. 2, Mrs. Pattisson, Maldon. *Silver-spangled.*—1, H. Pickles, jun., Earby. 2, H. M. Maynard, Holmewood, Ryde. *c*, Rev. F. Tearle; C. Turner; Mrs. Pattisson. *Gold-pencilled.*—1 and *c*, H. Pickles, jun. 2, W. Tickner. *Silver-pencilled.*—1 and 2, H. Pickles, jun.

Polands (Any variety).—1, W. K. Patrick, West Winch, Lynn (Golden). 2, J. Hinton, Warminster (Silver). *hc*, H. Pickles, jun. (Silver); W. K. Patrick (Golden). *c*, W. K. Patrick (Golden); W. J. Woodhouse, West Winch, Lynn (silver).

Game Bantams.—*Black-breasted and other Reds.*—1, W. B. Jeffries, Ipswich. 2, E. Cambridge, Cotham. *hc*, W. B. Jeffries; H. L. Cocksedge, Bury St. Edmunds; Nichols & Howard. *Any other Variety.*—1, Rev. F. Cooper (Duckwing). 2, Hon. E. Gifford, Ampney Park, Cirencester (Duckwing). *hc*, R. Swift. *Any variety except Game.*—1, M. Leno, Markyate Street (Laced). 2, E. Cambridge (Black). *hc*, Rev. F. Tearle (White); H. M. Maynard (Black); S. and R. Ashton, Mottram.

Any other Variety.—1, Rev. A. G. Brooke, Shrawardine (Malay). 2, W. Wildey, Cosham (Andalusian). Extra 3, W. Massey, Spalding (White Leghorn).

Ducks.—*Rouen.*—1 and 2, J. K. Fowler. *c*, Mrs. E. Wheatley, Ingatestone. *Aylesbury.*—1 and 2, J. K. Fowler. *hc*, Mrs. Pattisson; H. S. Wiggins, Stowmarket; W. Tippler. *Any other Variety.*—1 and 2, M. Leno (Viduata Whistling Duck and Mandarin). *c*, S. & R. Ashton.

Selling Class.—1, H. Dowsett (Brahma). 2, J. Mansell, Longton, Staffordshire (Spanish). *hc*, J. F. Sillictoe, Wolverhampton (Spanish); H. H. Thompson, Coleshill, Farringdon (Gold-pencilled Hamburgh); S. Felgate, Langham, Essex (White Cochins). *c*, G. Barton (Brown-breasted Red Game) (2); H. M. Maynard (Light Brahma); H. S. Wiggins (Coloured Dorking); J. Norman (Coloured Dorking); E. W. Shalford (Black Spanish); W. J. Woodhouse (Black Red Game).

Selling Class.—1, J. Frost (Coloured Dorking). 2, H. Dowsett (Brahma). *hc*, T. Rogers, Walsall; J. Norman (Coloured Dorking) (2); E. W. Shalford (Black Spanish) (2); D. C. Campbell, M.D., Brentwood (Dark Brahma). *c*, C. Turner, Great Baddow (Silver-Grey Dorking).

PIGEONS.

Carriers.—1, H. Yardley, Birmingham. 2, F. W. Metcalfe, Cambridge.

Pouters.—1, P. H. Jones, Fulham. 2, Withheld.

Tumblers.—*Almond.*—1, 2, *hc*, and *c*, J. Ford, Monkwell St., Loadon. *Any other Variety, Short-faced.*—1 and *c*, J. Ford. 2, P. H. Jones (Kite).

Owls.—1 and *hc*, P. H. Jones. 2, H. Yardley.

Fantails.—1, H. M. Maynard. 2, P. H. Jones. *hc*, H. Yardley.

Jacobins.—1, W. E. Easten, Hull. 2, R. Richardson, Beverley.

Turbits.—1, R. W. Richardson. 2, G. H. Gregory, Taunton. *hc*, H. Yardley. *c*, T. Holmes, Lower Sydenham.

Barbs.—1, H. M. Maynard. 2 and *hc*, H. Yardley. *c*, P. H. Jones.

Nuns.—1, H. Yardley. 2, W. E. Easten.
Trumpeters.—1, P. H. Jones. 2. E. Sheerman, Springfield, Chelmsford.
Magpies.—1, H. Yardley. 2, P. H. Jones.
Dragoons.—1, J. Mitchell. 2, A. W. Wren, Lowestoft.
Archangels.—1, J. Bowes. 2, H. Yardley.
Antwerps (Best pen of four working).—1, H. Yardley. 2, H. Laver.
Any other Variety.—1, S. A. Wyllie, East Moulsey (Runts). 2, H. Laver, Colchester (Silver Runts). *hc*, Hon. Mrs. Paget, Scole (Starlings and Isabels). *c*, J. Mitchell (Tumbourettes); J. F. Bishop (Porcelains).
Selling Class.—1, C. Norman (Black Trumpeter). 2, H. S. Wiggins (Pouters). *hc*, L. Wren (Black Carriers). *c*, Hon. Mrs. Paget (Black Fantails and Starlings); H. Yardley; W. Bulmer, Spalding (Barbs); E. Sheerman (Trumpeters).

RABBITS.

Lop-eared (Any variety).—1 and 2, C. Gravil, jun., Thorne. (Whole class highly commended).
Himalayan.—1, W. Wood, Sible Hedingham. 2, S. G. Hudson, Hull.
Angora.—1, D. P. Gooding. 2, J. Boyle, jun., Blackburn. *hc*, C. King, St. John's Wood (2).
Any other Variety.—1, J. Allen, Ampthill (Silver-Grey). 2, S. G. Hudson (Silver-Grey). *hc*, J. R. Lunn, Hull (Silver-Grey). *c*, J. Boyle, jun. (Silver-Grey); S. G. Hudson (Silver-Grey).

Judges.—Mr. W. B. Tegetmeier and Mr. F. Esquilant.

THE BIRMINGHAM PHILOPERISTERON SOCIETY.

This was the sixth annual Show of the above Society, and as all its members are ardent breeders of fancy Pigeons, it has gradually progressed until very few shows can boast of classes so regularly well filled with first-rate specimens as this usually has. As a consequence, the competition is very close, and the decisions of the Judges are always very closely scanned. We may add that, for a spring exhibition, the entry of so many first-rate birds was almost without parallel.

The Carrier classes were, on the whole, the best the Committee has ever obtained, particularly the birds of last year's breeding. Mr. While took the first position with a most promising Dun, which, if no accident arise, will doubtless show to very great advantage in future years. The Black hen shown by Mr. F. Smith is not less worthy of especial mention. This gentleman took a silver cup with a grand pair of Barbs, the only entry in the class, and we strongly suspect the "utter hopelessness of winning" was the cause of so limited an entry, as exhibitors appear well to know who is in possession of first-class birds. Mr. Harry Adams, of Beverley, sent two pairs of Almonds that would be an honour to any breeder; the first pen were silver-cup winners, but the second-prize pen would have been an uncomfortably close run had the two not belonged to the same breeder. Everyone admired them. Dragoons and Antwerps were exceedingly good, and the display of Toy Pigeons was better than usual, several very choice newly-imported varieties being shown. It was remarkable that although the class for Fantails was by no means small, the generality of the birds were sadly rubbed in feather.

Carriers.—*Young Birds.—Black* or *Dun.*—1, J. F. While. 2, 4, and *c*, G. F. Whitehouse, King's Heath, Birmingham. 3 and 5, W. H. Mitchell, Moseley. *hc*, J. F. While; G. F. Whitehouse; J. Linnett, jun., Coventry; W. H. Mitchell. *Any other Colour.*—1, J. Watts, King's Heath. 2, Withheld.
Carriers.—*Black.—Cocks.*—1, F. Smith, Selly Oak, Birmingham. 2, G. F. Whitehouse. 3, W. H. Mitchell. *c*, T. Robson, Penkridge. *Hens.*—1 and Cup, F. Smith. 2, G. F. Whitehouse. 3 and *hc*, W. H. Mitchell.
Carriers.—*Dun.—Cocks.*—1, G. F. Whitehouse. 2, J. F. While. *hc*, W. H. Mitchell. *Hens.*—1, G. F. Whitehouse. 2, J. Watts. *c*, W. H. Mitchell.
Carriers.—*Any other Colour.—Hens.*—1, J. Watts. 2, Withheld.
Pouters. *Cocks.*—1 and 2, G. Sturgess. 3, J. Watts. *Hens.*—1 and 2, G. Sturgess. 3, J. Watts
Fantails.—1, J. F. While. 2, J. W. Edge, Birmingham. 3, H. Adams. 4 and *hc*, Mrs. A. F. Barnett, Erdington.
Almonds.—1, 2, and Cup, H. Adams, Beverley.
Balds and Beards.—1. J. W. Edge. 2, no competition.
Short-faced (Any other variety).—1, H. Adams. *hc*, G. Sturgess.
Jacobins.—1 and 2, J. W. Edge.
Trumpeters.—1 and 2, T. Robson.
Owls.—*Foreign.*—1, J. Watts. *hc*, G. F. Whitehouse. *English.*—1, J. W. Edge. 2, J. Watts. 3, Mrs. A. F. Barnett.
Turbits.—1, J. W. Edge. 2 and 3, T. Robson.
Barbs.—1 and Cup, F. Smith. 2, no competition.
Nuns.—1, J. Watts. 2, J. R. Bill, Birmingham.
Dragoons.—*Blue.*—1, J. Watts. 2, No competition. *Any other colour.*—1 and *hc*, J. Watts. 2, J. Coleman. *Single Birds.—Any colour.*—1, W. H. Mitchell. 2, G. F. Whitehouse. 3, J. Coleman. 4, J. Morris. *hc*, J. Coleman, West Bromwich (2); G. F. Whitehouse; J. Morris; W. H. Mitchell.
Magpies.—1, G. F. Whitehouse. 2, T. Robson.
Antwerps.—1, J. F. Cleveland. 2, W. H. Mitchell. *Cocks.*—1, W. H. Mitchell; 2, J. Watts. *hc*, J. E. Cleveland.
Swallows.—1 and 2, J. Watts.
Any other Variety.—1, 2, and Cup, W. Bankes. 3, J. Watts.
Single Birds (Fancy).—1 and 3, H. Adams. 2 and *hc*, J. Watts. 4, J. Morris.
Tumblers (Flying).—*Badges* (Black).—1, J. Massey, Lozells, Birmingham. (Blue).—1, J. W. Edge. *Mottles.*—1, J. Massey. *Single Birds* (Any variety).—1, J. Massey. 2 and 3, J. W. Edge.
Rosewings and Redbreasts.—1 and 2, J. Massey.

Mr. Edward Hewitt, of Sparkbrook, and Mr. Yardley, of Birmingham, judged all the strictly fancy varieties, and Mr. Walthew, of Birmingham, the flying Pigeons.

LEEDS ROYAL PARK BIRD SHOW.

A very aristocratic title certainly for a bird show, but a very happy one, as may be fully realised by a visit to the grand conservatory in the Park, containing so many beautiful plants and flowers, and so many fine birds of all classes, breeds, and colours, from the small Waxbills, Diamond and Coral-necked Sparrows, Indigo Blue-birds, Java Sparrows, Love-birds, and Parrakeets, to the larger kinds—viz., King Parrots, Grey and other Parrots, Cockatoos, and Great Macaws. Another visit to the above interesting place, situated about a mile and a quarter from Briggate in Leeds, increased one's familiarity with the Royal Park, with its finely laid-out walks, terraces, and grounds, the conservatory, the ponds containing gold and silver fish, the fountains, &c. Mr. Thomas Clapham, the Managing Director, devotes much time and attention to making the park what it is intended to be—a pleasant resort and place of recreation for the people.

The third annual Show opened in the large conservatory on the 4th inst. and will close to-day. The judging began on Friday morning, which was very foggy, but as the day advanced the sun shone with much power on the conservatory. The large tent or awning used at the recent Crystal Palace Show would have been of great service in screening the birds from the sun's rays, which fell with full force on the Norwich Canaries, the judging of which was delayed for the purpose of bringing home to the eyesight of the Judge the pure and natural colours of several of them as they *ought to have been*, not as *some* of them *were*. The publicity given to the "coloured specimens" at the late Crystal Palace Show, and the dastardly anonymous letter, bearing a Nottingham postmark, received by one of the Judges some time since, setting forth in elegant expressions the "ignorance of the Judges," did not deter the deep-dyed specimens (Norwich, and a Golden-spangled Lizard) from being shown and detected. Besides a host of fine-bred Canaries exhibited by breeders from various and distant parts of England, representing all the well-known breeds excepting the Scotch fancy, there was a splendid collection of British and foreign birds. The following are the awards:—

Norwich.—*Clear Yellow.*—1, 3, and *hc*, Moore & Wynn, Northampton. 2, T. Irons, Northampton. *Clear Buff.*—1, 2, and 3, Moore & Wynn. *vhc*, Bexon and Bennett, Derby. *hc*, A. Webster, jun., Kirkstall; G. Tuckwood, Nottingham.
Norwich.—*Marked or Variegated Yellow.*—1, R. Hawman, Middlesbrough. 2 and 3, Moore & Wynn. *hc*, Moore & Wynn; J. Close, Derby. *c*, H. N. Fosbrooke, Leeds. *Marked or Variegated Buff.*—1 and 2, Moore & Wynn. 3, W. Heap, Bradford. *hc*, Bexon & Bennett; G. Tuckwood; Moore & Wynn.
Norwich.—*Ticked or Unevenly-marked Yellow.*—2 and 3, Moore & Wynn. *Ticked or Unevenly-marked Buff.*—1 and 2, Moore & Wynn. *vhc*, T. Irons; G. Tuckwood.
Norwich.—*Crested Yellow.*—1, R. Hawman. 2 and *vhc*, Moore & Wynn. *Crested Buff.*—1 and 2, Moore & Wynn. *vhc*, H. N. Fosbrooke. *hc*, Bexon and Bennett.
Belgian.—*Clear Yellow.*—1, J. Close. 2, P. Rawnsley, Lidget Green, Bradford. *vhc*, J. N. Harrison. *Clear Buff.*—1, J. Close. 2, P. Rawnsley. *Variegated or Ticked Yellow.*—1, P. Rawnsley. 2, J. Close.
London Fancy.—*Jonque.*—1 and 2, C. Clark, Sutton, Surrey. *Mealy.*—1, T. E. Foster. 2, C. Clark.
Lizard.—*Golden-spangled.*—1, J. N. Harrison, Belper. 2, G. Tuckwood. 3, Stevens & Burton, Middlesbrough. *vhc*, P. Rawnsley. *Silver-spangled.*—1, J. N. Harrison. 2, Stevens & Burton. 3, G. Tuckwood. *c*, W. Heap.
Cinnamon.—*Jonque.*—1 and 2, T. Irons. *vhc*, Moore & Wynn; J. Spence; G. Cox, Northampton. *Buff.*—1 and *vhc*, T. Irons. 2, Moore & Wynn. *Marked or Variegated* (irrespective of Colour).—1, R. Hawman. 2, J. H. Hadland, Wallington. *hc*, Moore & Wynn.
Any other Variety.—1, Fairclough & Howe, Middlesbrough. 2, W. Heap, Bradford. 3, Stevens & Burton. *vhc*, Moore & Wynn; R. R. Hammond, Bradford.
Goldfinch Mule.—*Variegated Yellow.*—1, Stevens & Burton. 2, W. Chesney, Rudness, Goole. 3, W. L. Chapman, Northampton. *vhc*, P. Rawnsley. *Variegated Buff.*—1, Fairclough & Howe. 2 and 3, W. Barnes, Cannon St., London. *vhc*, W. Barnes; P. Rawnsley. *hc*, W. L. Chapman
Goldfinch Mule.—*Dark Jonque.*—1, W. Heap. 2, Stevens & Burton. *vhc*, T. E. Fosbrooke, Leeds; Moore & Wynn; W. Smith, Birmingham; G. Cox. *Dark Mealy.*—1, W. L. Chapman. 2, W. Smith. *vhc*, W. Heap.
Goldfinch Mules (Six in one cage).—2, W. Heap. 3, E. W. Lulham, Brighton.
Linnet Mule.—1, J. Spence, Sunderland. 2, W. Heap. *vhc*, W. E. Burniston, Middlesbrough.
Bullfinch.—1, W. Heap. *vhc*, A. Webster, jun.; G. Cox. *hc*, W. Smith.
Goldfinch.—1, W. Smith. *vhc*, J. N. Harrison; Fairclough & Howe; J. Spence.
Linnet.—1, J. Spence. *vhc*, A. Webster, jun.; J. N. Harrison; W. E. Burniston; Fairclough & Howe.
Skylark.—1, T. Haunan, Leeds.
Robin.—1, G. Cox.
Blackbird.—1, A. Webster, jun.
Starling.—1, Royal Park Company.
British Birds (Any other variety).—1, A. Webster, jun.
Birds of Passage and Migratory Birds.—*Blackcap.*—J. Bem, jun., Upper Wortley, Leeds. *Siskin* or *Aberdevine.*—1, A. Webster, jun. *British Birds* (six in one cage).—1, T. E. Fosbrooke.

FOREIGN BIRDS.

Cockatoos.—*Lemon* or *Orange-crested.*—1, Royal Park Company (2). *Leadbeater or Rose-breasted.*—1, E. Foster, M.D.
Parrots (Grey).—1, Royal Park Company.
Love Birds.—1, W. Brownridge, Leeds.
Parakeets.—*Australian Grass.*—1, Royal Park Company. *Roschill.*—1, W. Brownridge.
Small Parrots or Parakeets (Any other variety).—1, Royal Park Company.
Cocketeals.—1, Royal Park Company.
Lory (Any variety).—1, Royal Park Company.
Sparrows.—*Diamond.*—1, Royal Park Company. *Coral-necked.*—1, Royal Park Company. *Java.*—1, A. Webster, jun.
Nightingales (Virginian).—1, Royal Park Company.
Cardinals.—1, Royal Park Company.
Foreign Birds (Any other variety).—1, Royal Park Company (Blue or Indigo and Macaws).

Judge.—Mr. George J. Barnesby, Derby.

BAILDON ORNITHOLOGICAL SOCIETY'S SHOW.

This was held on the 24th and 25th of February. The thanks of the Committee and visitors are due to the ladies of Baildon for so tastefully decorating the room. Messrs. Garnett and Fawcett, Hon. Secretaries, with their assistants, paid the best attention to the specimens sent for exhibition, and a better prize-list is promised for another season. To their praise be it said, they despatched the catalogues to exhibitors promptly.

The first and second-prize Yellow Belgians were very good, but the second too rough and coarse in the feather. The first-prize Buff Belgian was very beautiful, and was closely followed by other good

birds. The Jonque and Mealy Norwich were not up to the standard but better than have been shown before. The first-prize bird in the Ticked or Variegated Class is celebrated. The Clear-crested Coppy were really first rate; the first-prize bird was a splendid Yellow, and the second not far behind. In Dark or Grey-crested, the first and third were really good birds, the second-prize going to a good Dark-crested Coppy. Clear Yorkshire were of the very best, and were all highly commended. In Evenly-marked Yellow Canaries, the first was a faultless bird. In Evenly-marked Buffs, the first-prize bird was very truly marked on the eyes, wings, and tail, and the tail feathers were its own! The prize Cinnamons were a very fair lot. In Gold or Silver-spangled Lizards, the first bird was a splendid Silver. In Evenly-marked Goldfinch Mules, the first-prize bird, Buff, distanced all shown. In the Selling Class for the township of Baildon only, there were many good and cheap birds, and they changed owners very quickly; Dark Mules only were scarce. The third-prize bird was good, but pied on the breast. In Any other Variety of Mules, a Linnet Mule was first, and the second prize was taken by a Bullfinch and Goldfinch Mule. The Goldfinches would have been thought a nice lot, providing the first-prize bird had not been there; he put them all completely in the shade. Linnets were good. In the class for Any other Variety of British Birds, a really splendid Mountain Finch won easily.

Belgian.—*Clear Yellow.*—1, J. Ellis, Baildon. 2, H. Greenwood, Booth Town, Halifax. 3, W. Shackleton, Ilkley. *Clear Buff.*—1, H. Greenwood. 2, W. Shackleton. 3, J. N. Harrison, Belper.

Norwich.—*Clear Jonque.*—1, Moore & Wynn, Northampton. 2, J. Cockshott, Bingley. 3, G. Midgley, Bocking. *Clear Buff.*—1 and 2, Moore & Wynn. 3, W. Nowell, Baildon. *Ticked.*—1, R. Hawman, Middlesbrough. 2 and 3, Moore and Wynn.

Clear Crested.—*Coppy, Buff or Yellow.*—1, W. Shackleton. 2, Hutton and Fawcett. 3, J. Fawcett, Baildon.

Crested.—*Dark or Grey.*—1 and 3, Moore & Wynn. 2, W. Shackleton.

Yorkshire.—*Clear Yellow.*—1, W. Shackleton. 2, T. Pimperton, Baildon. 3, Hutton & Fawcett. *Clear Buff.*—1, Hutton & Fawcett. 2, J. Boddy, Baildon. , Fairclough & Howe.

Evenly-marked.—*Yellow.*—1, Stephens & Burton, Middlesbrough. 2, R. Hawman. 3, Hutton & Fawcett. *Buff.*—1, H. Greenwood. 2, Stephens and Burton. 3, J. N. Harrison.

Lizard.—*Golden or Silver-spangled.*—1, J. N. Harrison. 2, Stephens and Burton. 3, R. Hawman.

Cinnamon.—*Buff or Yellow.*—1, Moore & Wynn. 2, J. N. Harrison. 3, J. Spence, Sunderland.

Goldfinch Mule.—*Evenly-marked Buff or Yellow.*—1, W. & C. Burniston, Middlesbrough. 2 and 3, E. Stansfield. *Dark, Buff or Yellow.*—1, Stephens and Burton. 2, Moore & Wynn. 3, E. Stansfield. *Any other Variety of Mules.*—1, J. Spence. 2, E. Stansfield. 3, W. & C. Burniston.

Selling Class (Local).—1 and 2, Hutton & Fawcett. 3, J. Ellis.

Goldfinch.—1, J. Cockshott. 2, J. Spence. 3, N. Whitaker, Baildon.

Linnet.—1, W. & C. Burniston. 2, A. Webster, Kirkstall, Leeds. 3, Fairclough & Howe.

Any other British Bird.—1, A. Webster. 2, J. Sharp. 3, A. Pimperton.

Pigeons.—*Carriers.*—1, W. Lund, Shipley. 2 and 3, J. Watkins, Marden. *Dragoons.*—1, E. Beldon, Bradford. 2, T. Speight, Bradford. 3, W. Lund. *Turbits*—1 and 3, W. Lund. 2, H. G. Poole, Bradford. *Antwerps.*—1, W. Lund. 2, I. Lancaster. 3, J. W. Collinson, Halifax. *Owls.*—1, W. C. Dawson, Otley. 2, J. Thresh, Bradford. 3, H. C. Crowley, Bradford. *Tumblers.*—1, E. Beldon. 2, W. Lund. 3, F. Bentley, Baildon. *Any other Variety.*—1, W. C. Dawson. 2, E. Beldon. 3, W. Lund. (Local).—1, S. Jagger, Baildon. 2, W. Lancaster, Baildon. 3, W. Boocock, Baildon.

Judges.—*Canaries, &c.:* Mr. J. Taylor, Middlesbrough-on-Tees. *Pigeons:* Mr. W. Cannan, Bradford.

MULES AT THE CRYSTAL PALACE BIRD SHOW.

These were neither so numerous nor of such quality, on the whole, as last year, when they numbered 141 as against 87 this year. The great ambition of Goldfinch-Canary and Linnet-Canary Mule-breeders is to produce an absolutely clear bird—*i.e.*, one free from the taint of even a single dark feather—a task requiring the exercise of patience as great as that belonging to the patriarch whose possession of that attribute is proverbial; indeed, it is averred by many that it is only his lineal descendants who should attempt it. When it is taken into consideration that, to begin with, it is not easy to breed a Mule at all; that 75 per cent., or I might as well say 90 per cent., of those bred have not a single light-coloured feather other than the silky flue on the under part of the body; that not one in a hundred is decently marked; and not one in a thousand clear, or what is as difficult to obtain—exactly marked, having no foul feathers whatever, some idea of the magnitude of the lottery may be arrived at; and before investing in a Goldfinch, which may or may not feel disposed to enter into matrimonial relations with the Canary, one may well consult his genealogical tree in search of a strain of "staying" blood. There are instances on record in which a shilling lottery ticket has eventuated in a fortune, and there are traditions among the fancy, telling how this and that one bred a Clear Mule at the first attempt. One is as remarkable as the other, but those are not wanting who would attribute such good fortune to connection with a gentleman who is popularly represented as belonging to anything but a "Clear" class.

Such being the difficulties of the case, and such the exceedingly small per-centage of Mules approximating to perfection, it is evident that the balance of power, as regards numbers, is in the hands of the Ticked and Unevenly-marked classes, which, with the entirely Dark Mules, form the bulk of the population of this community of hybrids, including among them birds of extraordinary beauty, vastly superior in size, colour, deportment (there is a gentlemanly bearing about a well-bred Mule), and quality of plumage to many of those which base their claim to be ranked among the upper ten upon the cut of their coat, just as a "Noah's ark" covers many a Mule now-a-days. These outsiders—the irregularly-marked Mules, are virtually excluded from competition at the Palace, the prize list providing really for only two descriptions of birds apart from the dark self-coloured—that is, for Clear birds, or birds so nearly approaching that point as to require some skill to discover the defect; and secondly, for Evenly-marked birds, assuming the word "Variegated" to have the same meaning as in Classes 3 and 4. This being so—and the few entries in the "Clear for choice" classes (only half a dozen in all) support my view—I think that any bird approaching exactness in marking to such a degree as to make it what is understood and recognised as an Evenly-marked bird, is, if found in this class, wrongly entered, and should be disqualified, no matter how slight its markings. Such a bird was 527 (J. Doel), first prize, one which never should, under any circumstances, have come into competition with what is meant by "Clear for choice" birds. If absolutely Clear Mules be so rare that, for reasons financial or otherwise, it be not deemed expedient to give them a separate class, but to include among them those which are almost but not quite spotless, justly giving precedence to the perfect bird, by all means let the line of demarcation be clearly drawn.

In the Buff class there could be no mistake as to first and second, 529 (Ashton) and 530 (Doel), being two gems without a flaw, but 529 much the higher colour of the two. No. 531 (Doel), highly commended, was open to the same objection as 527, being pencilled on the eyes, besides having other marks.

The stars in the Variegated Jonques were 540 (Ashton), first and cup, a rubicund-faced friend, the hero of many fights, with a blaze of colour such as one might expect to see in a bird addicted to cups, and 543, 544 (Doel), second and third, both exquisite specimens. The commended birds also were well worthy their v.h.c., and specially 539, which, though defective in the pencilling of one eye, is my embodiment of an aristocratic Mule. It has a "port and a presence."

Variegated Buffs were good, though not extraordinary, but the first prize, No. 549 (Fairclough & Howe), was a grand, lusty bird, and fairly ranks high among Mealy Mules of known reputation. One or two, however, will have to die before it can succeed to the crown. Mr. Doel's birds here deserve special mention, all being young; 564, marked on eyes, wings, and tail, taking second, with a neat bird of Mr. Baxter's, of Newcastle, third. The Rev. V. Ward showed two which, without much pretension to be considered Variegated Mules, were not to be excelled, if equalled, in condition by any birds in the class.

In Dark Mules there was nothing calling for special comment, and Mr. Spence's Brown Linnet Mule has been described in my notes on Darlington.

In the "Any other variety" class the first prize fell to 602 (W. Yeoman, Leeds), described as a hybrid between the Bullfinch and Canary. That it is Bullfinch and ——, there is apparently no doubt; but in the absence of direct evidence of the fact I should hesitate to name the Canary as the other parent. It is more like Bullfinch and Chaffinch—an opinion which was entertained by a select committee of the *cognoscenti*, who sat upon it in solemn conclave assembled. Mr. Stansfield's Bullfinch-Goldfinch was there, but not in all his glory, for 610, a similar hybrid and much-improved bird, was close on its heels, the third honour very properly going to a Bullfinch-Linnet Mule, of which there were two shown, besides Goldfinch-Linnet, Goldfinch-Greenfinch, and other rarities. The groups I will pass, simply envying Mr. Walter his three-prize "six Norwich," and bestowing an extra word of praise on Mr. Doel's six Goldfinch Mules, which were pictures of condition, as were the second six of Mr. Ashton's.—W. A. Blakston.

UNITED KINGDOM RABBIT SOCIETY.

I think Mr. Millington's suggestion for establishing a "United Kingdom Society" would be the means of putting the question to the test, and the sooner it is commenced the better; but I would suggest the subscription be 2*s.* 6*d.* instead of 1*s.*, and that each member have the privilege of exhibiting one pen annually free of cost.

It is essential for the well-being of such a Society that all petty jealousies should be sunk, and that every variety of the fancy should be fairly represented. For my own part I am a Lop-eared breeder, but I can admire perfection in any class, and am prepared to give it its due reward. While writing on this subject I would remark that it has often occurred to me that a great mistake is made by most societies in awarding to the Lop-eared variety the best prize for length of ear irrespective of every other property; for example, a Rabbit may be produced with tremendously long ears, may be hare-legged, blear-eyed, splay-footed, of very bad colour, ugly in form—in fact may be a ricketty sickly animal, and probably may die within a month or two owing to excessive forcing. Now, to obviate this I would suggest that every Rabbit competing for the first prize should be not less than eighteen months old (about half the age of a healthy Rabbit), and that it should be well upon its legs, of good colour, and have a clear eye. Should this principle be adopted I am sure we should have a better supply of perfect Lops.

Should Mr. Millington prosecute his scheme I shall be glad to co-operate with him.—T. I. Inman, *Hackney*.

A RABBIT FANCIER'S TROUBLES.

I entered four Lop-eared Rabbits and an Angora at the last Portsmouth Show. I was up betimes on Monday morning seeing my pets made comfortable, and got them off as soon as possible to the railway station, paid 15*s*., and sent them off per passenger train. Judge of my feelings, on receiving a catalogue, at finding that my Rabbits were never mentioned, and that my friend in the fancy at Doncaster had taken the cups. Next morning a polite note from the Secretary very solemnly told me that my Rabbits were "too late, or else they would have done something." What important words these, and how soothing! but the greatest surprise of all was the addition that he received them on Tuesday evening. I may add that I received them back about six o'clock on Saturday evening, very nearly lost with cold and hunger. Where has the Society for the Prevention of Cruelty to Animals its head quarters, as this seems a case for it? Now, a good deal of this trouble would be avoided by such a club as Mr. Millington mentioned in a recent number. Are Rabbit fanciers to pack and send Rabbits off on Sunday? this will not do, at any rate not for me—I love that day too well. Thus have I spent 30*s*. in railway fare, and 12*s*. 6*d*. entrance, all to no purpose, and simply because the Portsmouth Show opened on Tuesday instead of on Wednesday, as would have been pointed out by the United Kingdom Rabbit Club; and the other point this Club would rectify would be to enter the all-meaning words "too late" opposite those names which required it, and not lead the public to believe that our Doncaster friend with his two Rabbits had beat all comers, and especially my Rabbits, which beat his at Leeds.—G. H. Hirst.

VENTILATION OF HIVES DURING WINTER.

The "Lanarkshire Bee-keeper" states that he has found the plan of lowering the temperature of his hives by means of ventilation, prove very successful in preserving the lives of his bees during the prevalence of snow in spring. May I ask him to favour the readers of "our Journal" with a particular description of the process whereby this desirable result has been accomplished? What kind of ventilator does he employ? and when is the best time to apply it? Ventilation has been greatly recommended by some high authorities, but a would-be instructor in a book recently published, if I remember rightly, pronounces the whole thing "a mistake." That it can only be so when ill-timed, or the process is faulty, is the opinion of most apiarians who have given it a fair trial. Messrs. Payne and Taylor paid great attention to the subject, and both concur in testifying that it is a valuable expedient for carrying off vapours in wooden boxes, which are liable, by becoming condensed, to render the combs mouldy and offensive. I have had too little experience of the use of ventilators to warrant my saying much respecting their merits, but I saw an attempt made a few years ago to give practical expression to the idea thrown out by the "Lanarkshire Bee-keeper."

In February, when the snow was on the ground, the bees of a common straw hive suddenly rushed out in great numbers to the open air. The loss of life, through their falling into the snow, was fearful, and to prevent further destruction of his property, the proprietor had recourse to the following plan. Procuring a thick piece of wood he cut a row of doorways in it, of a size just sufficient to prevent the egress of bees, and then fitted it into the entrance. The plug at the top of the hive, which might be 1 inch in diameter, was next withdrawn, and a milk pan was inverted over the hole, both skep and pan being covered with a thick coat of straw. This device was very successful in keeping the bees at home, but the cure was as bad as the disease, for the hive was ventilated to death. In the midst of plenty every bee perished; the community were unable to bear up against the increased cold caused by a draught of air, which could only have been slight, passing up through the hive; and when the plug a few days afterwards was withdrawn, the bee-master had the mortification of seeing nothing but lifeless clusters on the floorboard and between the divisions of the combs. Is it, then, safe or expedient to have recourse to ventilation at a time when, after a lengthened confinement, the loaded bees take steps for obtaining relief?—R. S.

OUR LETTER BOX.

Books (*W. S.*).—There is no book on Cochin-Chinas only. "The Poultry-Book for the Many" contains relative directions for rearing them, notes on form, &c. It can be had from our office by post, if you enclose seven postage stamps with your address. (*J. Hunt*)—"House Dogs and Sporting Dogs." Van Voorst, London. Only one edition. It is a small volume.

Crêve-Cœurs (*Henwife*).—The white deaf-ear is not an important point in any way with a Crêve-Cœur cock. It is, as in the case of a Dorking cock, immaterial. Many Crêve-Cœurs have them remarkably developed at this time and during the spring. It is not desirable, and if we had to choose between two birds equal in every point save the difference of the ear-lobe, we should take the bird without one. We nevertheless repeat, it is not a disqualification. You may safely set the eggs.

Houdans (*A. C.*).—The chickens hatched will take after both cocks; some will have the small size, others the faulty plumage, both modified by the quality of the hens. What do you mean by faulty plumage? Do you mean coloured feathers? Straw-coloured are a simple disadvantage; few cocks are without them. Red feathers disqualify. The birds bred from a Light Brahma hen running with a Dark cock will be of mixed plumage, probably white breasts, great predominance of white in the hackle, and black and white backs and saddles. They lose no valuable properties, but being cross-bred they are fit only for layers and ordinary farmyard fowls. We do not think they need be separated for more than a fortnight, or at most three weeks, for the purpose of changing the cock, before the eggs may be set as the produce of the new bird. What do you mean by the sandy tinge? A Dark Brahma cock has only a "suspicion" of deep brown on the wing, and he is better without that. The Silver-Grey Dorkings are not better in Scotland than in England, but the majority of Scotch amateurs will not look on any feather as pure. We do not advise you to apply to any agent to buy or claim birds at a show. If you can go yourself, do so. If not, try to find a competent friend. If still unable, write to the Secretary of the Birmingham Show to claim for you prize birds of the breeds you require, if they are to be had at a price you must name. We name Birmingham because all the classes there are good. In smaller shows, although they may be good as a whole, yet some classes are mostly weak, and they might be those in which you were most interested.

Fowls in Rooms—Road Grit (*Nottingham*).—We much fear you will do little good keeping fowls in rooms. The flooring will not suit. You can obviate that by covering it some inches—3 or 4—with road grit. The latter is made up of the scrapings of a road and the trimmings of the side paths when the gutters are cleaned and the road made straight. This has the property of being always dry, and there are also among it many roots of grass, of which the fowls are fond. You will have to supply the fowls with sods of growing herbage daily, and with bricklayers' rubbish. They would want no roosting place, as they are under cover, and will choose for themselves a sheltered sleeping place. If you will take this trouble you may keep them and set eggs. You could not rear chickens in such a place. You could keep Brahmas, Cochins, Spanish, or Crêve-Cœurs.

Hen's Legs Become Coarse (*A. W. J.*).—Your hen has the recently imported malady which has been called the "poultry elephantiasis." It is a tiresome disorder, and can only be treated by frequent lubrications with compound sulphur ointment.

Drake Chasing Hens (*O. A. G.*).—We do not see why you should remove the drake from the Ducks. The eggs will probably be good throughout the laying, but there is nothing to gain by removing the drake.

Dorking Chickens Dying (*O. C.*).—If the chickens die of weakness there is something wrong in the feeding. When hatched early—in February or before—they should have strong beer to drink instead of water. Young chickens should have chopped egg, bread soaked in beer, bread and milk, coarse cooked meat chopped fine, curd, and dough made of ground oats if to be had; if not, of oatmeal. It is possible your chickens die from being infested with vermin. In this case your remedy will be to put heaps of dust and road sand close to the rip in which the hen is confined. Water strongly camphorated is an excellent thing for all poultry, and where that is used there is seldom any serious disease. Of course you keep the hens shut up in their rips till the chickens are six weeks old; if you do not, then do so, and feed as we have described. You ought then to rear nearly all your chickens.

Food for Ducks (*J. C. W.*).—We know no better food. You need not be uneasy at having no eggs; many people have none, especially where the Ducks are two or three years old. There is not a week lost, and you need not be uneasy though you have none for the next three weeks.

Roup (*Henricus*).—Roup is not so contagious as it used to be years ago. It is, nevertheless, a great plague and nuisance in a yard. Your remedies have not failed, as probably without them the birds would have died. Give them strongly camphorated water to drink. The offer of nine Silver-spangled Hamburghs for 50*s*. was tempting, as good birds are worth more. It does not, however, palliate the offence of sending diseased birds. These cheap lots generally have some fault, defect, or disease that makes their owners anxious to be rid of them.

Tumour in Pullet (*E. E. F.*).—It may be the hen has a tumour, and if so it will be well to kill her at once. Such are common among old birds. But the same appearance would proceed from an egg-bound hen or pullet, and it frequently does so at this time of year. The cure is to pass a wing feather saturated with oil down the egg-passage till it reaches the egg, which will be laid at once after this assistance. Your fowls are well managed, and therefore profitable. Your Ducks and hens give an average of ninety-four eggs from each bird. We can only guess the value of your stock because we have not seen it, but we should not think 5*s*. each more than their value. It is probably less than many of them are worth.

Fattening Dorkings (*M. W.*)—Your poultry-woman does not understand her business. Fowls will keep in good fleshy condition if well fed while running about, but they will not fatten. They should be put in close confinement in a warm, semi-dark, and quiet place, such as is afforded by the outhouses of gentlemen's premises. They may be peckers, and fed on a board three times a-day, or put in a coop and crammed. In both cases they must have no liberty, and must be fed at daybreak. We advise you to buy Beily's book on fowls, which gives full instructions, and devotes a long chapter to the subject. The food should be oatmeal and milk; there should be no mixture of pollard with it. Hen Turkeys may be kept till they are four years old, but careful breeders generally change the cock every other year. The Cambridge and Norfolk are both very good; the former are rather the larger. The same remark applies to Geese. They may be kept five or six years, but the gander should be changed. Seven Geese are too many for a gander, four are sufficient.

Hen Nesting but not Laying (*C. J.*).—Your hen, if not diseased, either does or will lay. Very many have not yet begun, and many are

condemned now like yours; but she will yet prove she has lost none of her valuable properties.

CHICKENS DEAD IN THE SHELL (*H. C.*).—You did not lose your chickens because the inner membrane of the egg was so thick, but because you did not moisten the eggs. They should be wetted every day for ten days before they are hatched, otherwise the chickens cannot make their way out. When the hen is off sprinkle water over each till it is wet. The round shape of the egg indicates that the shell is not so strong as it should be. If the run is deficient in lime, throw down some bricklayers' rubbish. They will hatch, but as such eggs are thin-shelled we should prefer to set perfectly formed ones.

BRAN AS POULTRY FOOD (*Nemo*).—We are quite aware that there is nourishment in bran, but as a poultry food it is worthless. The far larger portion passes through a fowl undigested. It helps to fill the bird's crop, but sawdust would do that at less expense. Such a mixture as rice and bran is about the least nutritive diet fowls could be put upon.

GROUND OATS (*Lemon Buff*).—The sample you send is more like bruised than ground oats. They would mix as coarse as sawdust, whereas in properly ground oats the skin, which in this sample is whole, is ground so fine that the whole assumes the appearance of coarse flour, and mixes almost as well. Experiments are being tried to grind them near London. As soon as it is satisfactorily done we will communicate with our readers. The sample from "*J. S. S. M.*" is good.

COST OF A FOWL'S KEEP.—Is there not some mistake in "E's." statement, that he keeps his Brahma fowls for 1½*d.* a-week each?—G. C.

BLUE JACOBINS.—Mr. A. Valabere, Rose Villa, Merton Road, Tooting, S.W., says that he can give "K. P." useful information, having kept the variety many years.

CARRIER PIGEONS (*Carrier*).—You will have found the needed information in our "Pigeon Book." If you require further information on any point please to specify it.

MATCHING DRAGOONS (*W. Torr*).—We are no friends to crossing colours when it can possibly be avoided, too much mischief has been done already in this way among fancy Pigeons; so we advise you to mate blue with blue, and the white with the silver, if you must. The fruits of a cross chiefly depend upon there having been crossed blood in the birds before. Thus we have known two red Pouters produce blue young ones because blue blood was in the parents' veins. If no crossed blood, the result may be clear young of either colour, but more probably of patched colour. Bathe the damaged eye wattle with a mild solution of alum in water.

CANARY'S SEIN IRRITATED (*Norwood*).—If the bird is suffering from the attacks of the red mites, dust it well with flowers of sulphur, blowing this well into the feathers. Discontinue all stimulating diet, such as hemp; feed only on Canary seed, and give a plentiful supply of green food.

BULLFINCH AND CANARY MULE (*Bullfinch*).—I do not think the feat has ever been accomplished—that is, the production of a Bullfinch-Canary Mule. The hen Bullfinch will enter into the most friendly relations with the Canary, and make the most amorous overtures to him. I had one which would flirt for ever, and now have two which no doubt will be guilty of the same unmaidenly conduct. But my Canaries were very Josephs of virtue, and resisted all the blandishments of the syren. If "BULLFINCH" will send me his address, I will tell him more about it.—W. A. BLAKSTON.

PRICE OF BEES (*Abeille*).—The value of bees varies very much in different localities. A strong, well-provided stock may in the spring be considered worth 20*s.* to 30*s.*, and an early swarm of pure Ligurians about two guineas.

FRUSTRATING HIVE-BREAKERS (*A Subscriber*).—The plan of alternately closing the entrances of your plundered and plundering hives may ultimately succeed in saving your assailed bees from destruction if continued until out-door collections begin to be made; but when once a hive has found out a weak neighbour and effected an entrance, it is liable to resume its predatory habits whenever a favourable opportunity occurs. Where practicable, it is well to remove the freebooters or their victims to the distance of a mile for a few weeks. If you wish to try the effect of carbolic acid in frightening away corsairs, you have only to dip a feather in the liquid and wet the entrance of your weak stock all round, letting fall at the same time a drop or two of the acid on the landing. Should robbers persist in their attacks, keep up the odour by repeating the process as opportunity offers during the course of the day. It is desirable, also, to have the entrance narrowed to admit the passage of only two or three bees at a time.

REMARKS.

1st.—A fine day but colder.
2nd.—White frost in the morning, slight haze at night, but a fine day.
3rd.—White frost in morning, but sunshine in the middle of the day. Lunar halo at night.
4th.—White frost in morning, fine warm afternoon.
5th.—Fine afternoon, very bright moonlight at night.
6th.—Fine morning, cloudy afternoon, occasional showers in the evening, but very fine at night.
7th.—Rather dull in the morning, but fine in afternoon, high wind at night, with sudden dip of the barometer.

A fine week, temperature above the average, and daily range very considerable—*e.g.*, 25.0° on 2nd, 31.4° on 3rd, and 29.0 on 4th.—G. J. SYMONS.

METEOROLOGICAL REPORT FOR FIRST TEN DAYS OF JANUARY.

THE following report is given with the view of rendering complete from the beginning the series of Meteorological Reports which commenced at page 60.

REMARKS.

1st.—Overcast, except in afternoon; calm day.
2nd.—Dull unbroken cloud throughout; very cold.
3rd.—Overcast; maximum temperature at 10 P.M.
4th.—Dull.
5th.—Overcast in morning and very cold, fine afterwards, and warmer at night.
6th.—Fine morning; rain in afternoon; cloudy at night.
7th.—Fine and warm in morning; showery afterwards.
8th.—Moderately fine, with occasional slight snow showers.
9th.—Overcast, with snow and sleet.
10th.—Snow in early morning; cloudy throughout the day.—G. J. SYMONS.

COVENT GARDEN MARKET.—MARCH 8.

WE have had a fair attendance of buyers on the market days, and things generally have put on a better appearance. The trade with the west of England and the Channel Islands has much improved, and the report for spring produce is good. Good dessert Pears are now comparatively scarce, and consist only of Easter Beurré and Beurré de Rance. Potatoes remain at last week's quotations. Ordinary Apples are still a very heavy trade.

From observations taken near London during forty-three years, the average day temperature of the week is 52.3°, and its night temperature 33.3°. The greatest heat was 58°, on the 21st, 1846 and 1859; and the lowest cold 2°, on the 17th, 1855. The greatest fall of rain was 0.51 inch.

PRIZES FOR HYBRID AND CROSS-BRED PLANTS.

I WISH to call the attention of our horticultural friends, and especially those interested in the growth of a really scientific feeling in the Royal Horticultural Society, to a set of premiums offered for hybrid plants under a certain general condition or proviso—namely, that the plants exhibited shall be shown in a manner calculated to illustrate the phenomena of hybridism and cross-breeding.

As it was obviously impossible to collect and produce on one given day anything approaching to a really high-class exhibition, it was thought that a special and continuous series of exhibitions through a whole season would give the necessary facilities.

In any gardening establishment, large or small, professional or private, the sowing, rearing, and flowering of seedlings, whether cross-bred or not, is a distinct pursuit, independent, as it were, of times and seasons. The subjects come into flower at all sorts of odd times, and have to be hunted for in odd corners. Some showy and valuable, some uncomely though interesting—fruits, flowers, weeds; branch and spray from the forest or shrubbery—these cannot be shown as you would show Geraniums or Azaleas, where the proper period of perfection for exhibition can be timed to a minute.

A larger number of premiums than usual is also resorted to in order to take in the productions of those humble aspirants who, having more brains than means and appliances, or who have taken up one special line of work alone, may yet bring forward small but important collections.

The practice of crossing plants for amusement, curiosity, or commercial purposes, has now become so common that no gardener with any pretension to skill in his profession would own to ignorance of it as part of his craft; but the number of scientific observers in this direction has been, and the conclusions arrived at, fewer; even over these hangs a shadow of doubt and uncertainty. We want facts—facts accompanied by real evidence; the hybrid plant, with its existence as such rendered evident to our sight by the presence of its parents at the same time, is such a fact. There it stands assured to our senses a living syllogism. And so, if possible, we wish to have all subjects shown in company with the two parents thereof.

That may be considered the main point. Of course, it will not always be possible to exhibit all three plants growing in so many pots. In such cases, one or even both parents may be shown as cut specimens. Nay, there are cases imaginable where neither parents nor offspring could be shown growing. Imagine, for instance, a small Oak tree with its two parents, venerable specimens of Quercus Cerris and pedunculata!

I will read presently a short list of imaginary subjects to explain what I mean by the following instructions to judges. Marks will be given in consideration of—

Great botanical interest.

Great horticultural interest.

Great horticultural merit.

New and hitherto unattempted crosses.

Difficult crosses.

Memoranda in writing to accompany objects exhibited will carry much weight, especially if well written, and evincing careful observation.

The above remarks were read by me at the last Wednesday meeting of the Royal Horticultural Society, when I observed that it would be necessary to consult with one or two competent authorities upon certain knotty points before publishing in full the conditions under which we desired the exhibition to be carried on.

Our original intention was that the exhibition should be a free and unrestricted one, admitting alike old and new plants, whether raised by the exhibitor or not, preferring, however, those raised by himself. The friends, however, whom I consulted—namely, our two Superintendents and several men of high standing in the profession, urged the exclusion of plants shown previously, and of such as were not raised by the exhibitor. These principles, if strictly carried out, would, I think, narrow prejudicially a wide field, and exclude a multitude of interesting objects. The following modifying rule will, I believe, meet the case, which is certainly one of some difficulty:—No plant to be exhibited without the consent of the raiser. This will obviate any clashing of interests, as in the case of one man exhibiting and profiting by the valuable productions of another.

It must be remembered that the premium is for a purely scientific object, less regard being had, upon the whole, to the intrinsic value of the objects than to their bearing upon a certain definite subject—that of hybridism and cross-breeding. It is to be hoped that it will be met in a like spirit, and will be looked upon and forwarded as an attempt in aid of the true interests of both the science and art of horticulture.

I conclude by expressing a hope that this may be the forerunner of a series of premiums to be held in future years for special scientific objects, and that the Fellows in general, both private and professional, will come to the aid of their Council in raising their Society to the position it once held, and might hold again, as the fountain of horticultural science.

The following imaginary, or rather suggestive, list was drawn up with the view of explaining some of the foregoing remarks as to the nature of the objects to be exhibited.

OBJECTS OF BOTANICAL INTEREST.

Ixia, Sparaxis, and Tritonia crossed with each other.
Primrose with Cowslip.
Elisena with Ismene.
Chelone with Pentstemon.
Meconopsis with Papaver.
Tigridia with Phalocallis.
Corbularia with Narcissus.
Convolvulus, Calystegia, Ipomœa, and Pharbitis with each other.

All these crosses if effected would assist botanical science by the determination of affinities.

OBJECTS OF FLORICULTURAL INTEREST.

Tulipa sylvestris, oculus-solis, snaveolens (Van Thol), and the early Tulips, crossed with each other, and with the best late-flowering show sorts.

Primrose and Polyanthus inter-crossed to produce new forms capable of after-improvement by the florist.

Anemone coronaria with sylvestris, apennina, and various others.

The garden Hyacinth systematically cross-bred,
The Tea-scented Rose crossed with the Yellow Briar race, also its yellow forms with Rosa alba, to produce fragrant white and yellow Perpetuals.
Pelargonium scntatum with Ciconium, to verify or disprove the capability of union between the Scarlet Geranium and the Ivy-leaf.
Carnation and Picotee.
Tom Thumb, or other plain-leaved Geranium, crossed with Mrs. Pollock, Golden Chain, and Alma. Baron Hugel, or other dark-zoned sort, with the same three descriptions of variegation.
Aquilegia glaudulosa with other Columbines.
British wild flowers, as Veronica, Ranunculus, Lonicera, Digitalis, Gentiana, crossed with allied exotic species.
Common Sloe with Green Gage.
Cherry Plum with the Green Gage.
Bramble with the Raspberry.
Crosses amongst the Brassicas, Onions, Carrots, and Radishes.
Black Currant and Scarlet Ribes.

DIFFICULT AND HITHERTO UNATTEMPTED HYBRID UNIONS.

Common Maize by variegated Japanese.
Common Pine Apple by Variegated Pine Apple.
Composite plants, as Aster, Dahlia, and Chrysanthemum.
Native Iris, fœtida and Pseudacorus, with the handsome garden sorts.
Salvia patens, with fulgens and splendens.
Mimulus cardinalis and the Musk plant.

Objects of great beauty and value will be readily produced from amongst the crowd of gorgeous new plants at our large establishments. Fruit and vegetable crosses are particularly desirable.

The above list must be, of course, considered as suggestive only and explanatory, showing what may, and probably can, be done in future seasons. To produce the crosses enumerated would be the work of from one to several years, but who knows but one or other may even turn up this very season?—R. Trevor Clarke.

SELECTIONS OF VINES AND EDUCATING THE ROOTS.

I have read Mr. Abbey's article at page 65, and I think Chaouch, or the Turkish Sweetwater, is quite worthy of being grown amongst the rest; it is the favourite Grape at Constantinople, a good grower, with handsome foliage, and is sure to attract the eye upon entering a vinery. The bunches are large and showy, and the berries large, oval, bright amber-coloured. As regards flavour, grown in a house with Lady Downe's, Burchardt's Prince [Aramon], Black Tokay, or Alicante, West's St. Peter's, Foster's White Seedling, and Trebbiano, this Grape was preferred by my visitors. Such has been my experience with it when grafted upon an American stock. It is also a good pot Vine, and hangs well.

In the list of Frontignans, the Early Golden, or Salamon's Frontignan, should not be omitted; it ripens as early as the Smyrna Frontignan, or, to give this its Levant name, Isaker Daisiko, and is first-rate in flavour and appearance. The ladies say, "What lovely Grapes!" Next comes the Primavis Frontignan, which is an offspring of Chasselas Musqué, known to some as Josling's St. Alban's, one of the finest of all Grapes when in perfection. The Primavis has large berries and bunches of the same high exquisite flavour as its parent, and the Vine is vigorous and fruitful. These two do not require so much heat as the Trovéren, and the three varieties named are the cream of the Frontignans, a class of Grapes having no equal when grafted and planted in inside borders, or grown in pots plunged, suitable for forcing or midseason supply. All the Frontignans named are croquant, or crackling, a quality much admired by the French.

Lady Downe's, like its twin sister, Foster's White Seedling, forces well. Although generally spoken of as a late Grape, so highly does it stand with me, that it is used for early and late work. As to Barbarossa, or Gros Guillaume, I urge the planting of grafted Vines only, these being worked on the Frankenthal, or better on the wild American stock, planting in inside borders not filled with manure, and in a heat a little above that of a Muscat house. Then this Grape will give every satisfaction, and be very fine both in bunch and berry. Allowed to hang till spring, it is one of the very best black Grapes grown; no Grape keeps longer than this, and it never shanks. Its noble bunches, weighing 6 or 7 lbs. each, might easily be mistaken for well-grown Hamburghs. Gros Colman is not mentioned. It is a noble Grape in bunch and berry, sure to attract attention at the dessert. Being a late Grape it should be left hanging as long as possible; in fact, do not cut it until the berries show symptoms of shrivelling.

As to educating the roots of the Vine, as Mr. Thomson so ably points out at page 61, all reflective readers will agree that it is of great importance. In planting Vines which I have purchased from time to time, I have had to contend with the difficulty of disentangling two or three leading roots, which, when uncoiled from the pot, would be 3 or more feet in length. To counteract this to some extent, I have shortened such long roots and cut off the tips of others with the view of forming a compact circle, the stem of the Vine being the centre, knowing that the new roots are produced at the ends of the old roots in the greatest quantity. In striking Vine eyes in 3-inch pots, I have cut off the points of all the quill-like roots when shifting into a pot only one size larger, this stopping of roots and shifting being repeated as fast as the pots became full of roots. By such means I have obtained a densely-packed ball of roots, in the soil for which a small portion of bone dust (borings of knife handles) was used. The shifting is discontinued when the Vines are in a 10 or 12-inch pot.

I stop my Vines when they are 6½ to 7 feet high, including the pot, whether they are intended for fruiting in the pot or planting. I afterwards reduce the height to, say, 5 feet, and thus I obtain fine plump eyes, sure to crop well, and the shortening aids the lower ones very much. Vines grown in soil with a large proportion of manure make stout canes, which please the eye, accompanied with large soft roots; but canes of less size and smaller harder roots are by far the best for all purposes.—R. M. W., *Fir View, near Sheffield.*

VARIEGATED KALE.

If fitness for its purpose constitutes one of the chief beauties of a thing, it is equally correct that a suitable position has much influence in causing us to view it favourably. To variegated Kale this reasoning applies with as much force as to anything; it is only a kind of Winter Greens, and planted in the kitchen garden with others of its class, it is not likely to strike one as possessing any very extraordinary merit beyond the common run of culinary vegetables. But select plants after the true colour of the foliage is apparent, arrange them skilfully in groups placed in such a position that the first view is obtained at some distance from them, and with suitable surroundings they are striking objects, producing an effect of such singular beauty as to render them valuable adjuncts for decorative purposes during a period of the year when bright-coloured hardy plants are scarce.

When the beds of a flower garden are arranged for the winter months with dwarf shrubs, some masses of variegated Kale might be introduced with good effect; but otherwise I would prefer seeing them as I did lately at Buxted Park—not in the flower garden, but in occasional groups away among the shrubs on the lawns, where the bright colours and curious foliage were seen with the best possible effect. Uniform in height and size, the plants had their colours so charmingly diversified as to reward one for the closer inspection which their singular appearance invited. Some of them had splendid rosettes of a bright crimson, others were of a delicate pink, and others had foliage of almost a black tint, rendered still more striking by the crimson frill surrounding it. Interspersed among these were others having white and yellowish white leaves, in some instances mottled and splashed with delicate green.

To those who are unacquainted with these pretty plants it will thus be evident that they possess sufficient variety of colour to produce bright variegated masses, which, while they harmonise with the shrubs, tend materially to relieve their monotonous greenery.—Edward Luckhurst.

RAISING AND PLANTING EARLY PEAS.

Reading an article on this subject in No. 518 of The Journal of Horticulture, by Mr. R. Mackellar, induces me to describe a successful mode that I have adopted here for several seasons for raising our first crop of Peas.

According to the number of rows of Peas required, I select paling rails about three-quarters of an inch thick, between 4 and 5 inches broad, and 12 feet in length. This is almost invariably the width of a border having a southern exposure. Then I take three pieces of the same kind of rails from 6 to 8 inches in length, and have a notch cut out thus—V; in this the other two rails are placed edge-to-edge. Three of the notched pieces are sufficient—viz., one at each end and one in

the middle, to keep the rails in their position; the end section of the troughs thus formed is therefore V-shaped. All that is necessary to make the whole secure, and yet facilitate removal as may be necessary, is a small nail in the end of each of the rests, to which a Willow may be fastened right across the rails and secured to the nail in the rest on the opposite side.

Before sowing, the ends of the troughs are closed with small pieces of turf, and the whole length is half filled with good loam. The Peas are sown as thickly as they would be in the open border; more soil is added and slightly pressed until it is level with the edges of the troughs, when these are removed to a vinery newly started, where they remain until the Peas are a couple of inches above ground. Then they are removed to a late vinery to harden off for a few days, after which, when a fine day occurs, the Peas are planted in their permanent quarters in the border.

This is done as follows:—A trench is cut the length of the troughs, and the latter placed close to its edge. The back of a knife is then run close along the inside of the rails to detach any roots which may have adhered to the wood; the Willows are cut, the rests removed, the Peas slip in an unbroken line into the trench prepared for them, and a little soil is drawn up to them. They are at once staked with a slight screen of branches to protect them from frosty nights and cutting cold winds, they receive a watering or two if the weather is dry, and by this plan earlier Peas are obtained than by sowing in autumn, and that without risk or disappointment.—Hugh Rose, *The Gardens, Grangemuir, Fife.*

PROTECTING GARDEN CROPS FROM RAVAGERS.

As seed time has pretty generally commenced, I offer to your readers a few suggestions which, if carried out, will prevent many of those disappointments we are subject to in cultivating the various products of the soil. Many are the enemies of the gardener—unsuitable soil, mice, birds, insects, &c., but these difficulties may all be overcome by experiments made by ourselves and by the experience of others. For the last forty years of my life I have carried on experiments in horticulture, some of which have proved very successful, and which, for the benefit of the readers of our Journal, I ask you to insert.

The subject of red-leading seeds has been very fairly made known, but I have been amused by the very delicate manner in which the use of red lead is sometimes recommended. I have employed it for horticultural purposes for upwards of sixteen years, and I find neither danger nor inconvenience in that use. As red lead is insoluble in water, the rootlets of plants cannot take it up. The advantages "R. F." speaks of are not over-, but under-rated. Much time and annoyance might be saved by extending the use of red lead to seed corn, especially where soils abound in wireworms. The expense is very trifling.

Then there is the woodlouse infesting the crevices in heated and other houses, causing great devastation. Carbolic acid in liquid, mixed with a portion of soil and spread round the inside walls, will cause woodlice to quickly disappear. Young Turnip plants in their early stage are often devoured by the saw-fly, whereas if a quantity of flowers of sulphur were put into a flour dredger and thus distributed over the plants as soon as they appeared, the odour of the sulphur being offensive to the insect, the latter leaves the plants for other prey. The same application to the Onion crop, when the plants have produced two leaves, will save the crop from the "grub."

I have always found a single thread of black worsted preveuts sparrows from taking the buds of Currants and Gooseberries, also the young Pea plants.—The Original Red Lead, *Knutsford.*

GOLDEN CHAMPION GRAPE.

I wish some of your correspondents would etate their candid opinion as to the merits of this highly-recommended Grape. Perhaps Mr. Thomson, who is, I believe, its father, may tell us not only its good qualities, but exactly how to grow it successfully.

My own experience is this. Two years ago I purchased a very nice well-ripened £2 2s. plant of Messrs. Osborn, and a better-rooted or better-looking young Vine I never wish to buy. I planted it carefully along with Golden Hamburgh, Muscat of Alexandria, Bowood Muscat, Muscat Escholata, and Black Hamburgh in an inside border made of the best materials. It broke slowly and badly, and was a long time in making a fair-sized shoot, but eventually I managed to get a tolerably good cane. I cut this back, and have treated it from the commencement much as I did the others, only giving it rather more water, as Mr. Thomson some time since in your Journal said that it needed more water than many other varieties. The next year it broke badly again, showing no bunches, and carrying yellowish unhealthy-looking foliage. Still I again succeeded in obtaining a fair cane, which appeared to be well ripened by the autumn of last year. Now, it has broken again without a bunch showing anywhere. The leading shoot is very strong and gross, so much so that I have stopped it to one leaf, hoping to make the other shoots stronger, but all to no purpose, for, as these appear no trace of a bunch is to be seen. I have several other Vines of the same variety, some in pots and some planted out, and they all go on in the same way. Golden Hamburgh, generally thought to be a weak grower and not overfond of showing bunches, growing next to it, has a promise of plenty of fruit, and all the other Vines in the house are doing very well, showing two or three fine bunches at every eye.

Now, as mine is not an isolated case of failure, every friend I have spoken to, without exception, having the same tale to tell, I think I am justified in saying that under ordinary treatment the Golden Champion is a very shy bearer. One of our largest Grape-growers told me that when it first came out he planted a house with it, and was so disgusted at its growth that he grubbed every Vine up. After one more year a good many more will do the same, unless some plain method of treatment can be laid down which will insure success.—Henry Nicholls, *Hawkhurst Lodge, Horsham.*

[We sent this communication to a very good authority, and this is his reply:—"My experience of this Vine is, I regret to say, not so satisfactory as I could wish. Planted out on its own roots it did not show fruit very well last season, but grafted on the White Tokay it bore tolerably well. It grows luxuriantly, but fails to ripen the side shoots well, so that the buds are in no condition to start the following year. Grafted on the Black Hamburgh, as Mr. Thomson has it, it does remarkably well, and is altogether a noble Grape. I would suggest this as the best means of growing it. There is no question about the fine qualities and noble appearance of the Golden Champion when it is grown well, but there is just as little question about its being of a very peculiar constitution, and by no means easy of cultivation."]

"WHO MOST PROMOTED MODERN ENGLISH GARDENING?"

The above is a question put to us in the expectation that a very different reply would be elicited than that which we give. Our answer is

The man of whom it is the autograph, though little known by his posterity, was one of the most remark-worthy men of the seventeenth century. William III., the Duke of Marlborough, the seven Bishops, Addison, and many others appear prominent on the historian's pages, for all were prime influencers of public affairs in every department of the State. But in all ages—and especially in their age—men in a lower grade were at work quietly but most effectually ministering to the improvement of the tastes and comforts of the entire community. They were labouring not to change dynasties, to maintain creeds, or to ameliorate the laws, or purify our literature, but they were advancing gradually and rationally on branches all leading to one terminus—the improvement of our domestic arts; among these is gardening, and George London was its chief improver.

There was a general desire for better horticulture; men of high attainments, such as Compton, Bishop of London, Sir William Temple, and Evelyn, wrote and expended liberally to promote the attainment of that better horticulture; yet despite these efforts, Evelyn was justified in remarking that, "Some Monsieurs, new come over, think we are as much obliged to follow their mode of gardening as we do that of their garments, 'till we become in both ridiculous." To oppose this

tendency to adopt French teachers were published the volumes having as authors Rose, London, Wise, Meager, Cook, and Switzer, all practical gardeners. but of them all London went to the front, for he not only told what should be done in English gardening, and provided the stores for doing it, but traversed all England to see that it was done judiciously. We will detail our grounds for this conclusion.

Switzer, in his "History of Gardening" in Queen Anne's time, observes, "To set down that history in its several particulars in this reign would require a volume, but will be for the most part summed up in the person and character of George London, Esq., Superintendent of the Royal Gardens, and Director-General of most of the Gardens and Plantations of Great Britain." No one need refer to a Biographical Dictionary for further information relative to George London—not one even names him, yet so often have we found him taking a prominent part in the public transactions of the period that we resolved to arrange the fragments we had collected into the best life's notice we could.

Of George London's parentage or birth-place we know nothing, but it may be presumed that he was not from elevated ancestors, since Switzer, who had been his pupil, merely observes, "I am not well enough informed, neither is it material, that I should go back to his birth and education." The latter was certainly limited, and Switzer speaks of "the little opportunity Mr. London had in laying a foundation of learning—this he overcame purely by industry—what he wanted in one he abounded with in the other."

London was an assistant to Mr. John Rose. who was gardener to Charles II. "at the Royal Garden in St. James's Park," and who ought to be remembered for "the encouragement he gave to Mr. London, who made afterwards the greatest figure ever gardener did." Mr. Rose, at the end of four or five years, sent him to France to observe how gardening was there conducted under its great practitioner, M. Quintinye; yet he went to learn what to avoid, as well as what to adopt, as is shown in the editions of Quintinye's works he aided in publishing.

Soon after London's return from France, he was preferred to the head-gardenership of Dr. Compton, Bishop of London, at Fulham Palace, "one of the first that encouraged the importation, raising, and increase of exotics. He had above one thousand species in his stoves and gardens, in which last he had endenisoned many previously thought too tender for this cold climate."

"Probably assisted in his great design" by Dr. Compton, London, with three coadjutors, founded

"That nursery and fund of gard'ning and plants, with which the nation was afterwards stock'd, I mean Brumpton Park, which, from the ingenious Mr. Evelyn, we may place above the greatest works of that kind ever seen or heard of either in books or travels.

"This vast design was begun some years before the revolution, by four of the head gardeners of England, Mr. London, gardener to the aforesaid Bishop of London; Mr. Cook, gardener to the Earl of Essex at Cashiobury; Mr. Lucre, garden to Queen Dowager at Somerset House; and Mr. Field, gardener to the Earl of Bedford, at the then Bedford House in the Strand, and appear'd to all that heard of it a work worthy of the greatest encouragement.

"One of their first undertakings was at the Right Honourable the Lord Viscount Weymouth's, at Long-Leat in Wiltshire, where these four partners abode every one his month, and in the intervals attended their own business; of which the new nursery before-named was not the least; but some time after Mr. Lucre and Mr. Field dying, and Mr. Cook selling his share, it was divided into two shares only, under Mr. London and Mr. Wise, who were the persons that have since carried it to its highest pitch, which, some years ago, was, by a person of judgment [Bowack], and no great friend to that undertaking, valu'd at between 30 and £40,000 (perhaps as much as all the nurseries of France put together.")

At that time Evelyn described it as "the greatest work of that kind ever seen or heard of." We can trace the changes occurring in the partnership by referring to the parish registers. There we find that in 1681, it was occupied by Lukars & Co.; in 1686, by Cook & Co.; in 1689, by Wise alone; and in 1694, by London & Wise, but they had been in partnership three years before, for we have their first account book, containing their signatures to each quarter's receipts and payments. The first is, "The first quarter, from December ye 28th, 1690, to March ye 29th, 1691."

On the pages of one of the account books of that nursery are entries as far back as 1671, when Mr. London must have been in the Bishop of London's service, as he frequently mentions "my master," occur the names of many gardeners familiar to those acquainted with horticultural literature. Thus there is this entry—"At Guilford, Mr. Meager, 9 dayes worke, and 7 dayes worke at ye Parke, 01—05—10." This was Leonard Meager, author of "The English Gardener," and other works that passed through many editions.

Leonard Meager worked at the Brompton Park Nursery during 1691 and 1692, at 9s. a-week. This was the highest wages they paid. His name appears as employed by Mr. London at Mr. Van Spreeks, and at Brompton seemingly when out of place, in 1693. Many curious bits of information can be gleaned from the same account books. We see in them that per-centeges to gardeners are no modern introduction.

There are many such entries as this —"Gave at the receiving Ld. Bullinge Brooks bill, 00—11—06." Wholesale prices are also recorded (1691). Thus

Pd. Mr. Hurst for 2000 of Yews..	20—03—00
For 250 Matts	05—14—00
For 4000 Horne beames	01—04—04
ffor 20 plumbs	00—18—06
Payd ffor 1 pott of double Virgin's Bower	00—02—06
for 400 of Artichoek plants	00—12—00
ffor 1 pecke Sandwicke peas	00—01—06
payd ffor 33 Orange trees	31—10—00

There were nurseries and market gardens previously, but they were either very small, or their stock was only the commonest of trees, plants, and culinary vegetables. Nor was that the worst of their deficiencies, for the owners were very ignorant of their correct names, and often sold the same variety under different titles. Evelyn gives this example—

"In Pears alone, a gentleman in the country sends to the nurseries for the Liver Blanch, Piguigny de chouille, Rattau blanc, &c., the English St. Gilbert, Cranbourn Pears (and several other names) when all this while, they are no other than the well known Cadillac."

London did much to correct this, and through the Bishop of London and the connections he secured during his own visits to the Continent, he enriched the stock of Brompton Park with a far greater variety of exotics than had previously been purchaseable. It gave birth to other similar nurseries, and his old masters being dead, Leonard Meager recommends purchasers of trees and plants to apply to his 'very loving friend Captain Garrle, dwelling at the great nursery between Spittle-fields and White Chappel, a very eminent and ingenious Nursery-man."

The Brompton Park Nursery continued to exist in its integrity till the year 1852, when the lease expired, and the ground, with some adjoining lands, was sold to the Royal Commissioners of the Exhibition of 1851. Some idea may be formed of the situation when we mention that what is now called Exhibition Road, South Kensington, was the principal central walk of the nursery; and the space now occupied by Prince's Gardens, part of South Kensington Museum, the whole of the Royal Horticultural Society's Garden, and Prince of Wales Road, formed a portion of the Brompton Park Nursery.

Many circumstances combined to enable London to take the leadership in gardening. The Bishop of London, Evelyn, and Sir W. Temple, all appreciated his skill, could aid him in obtaining exotics, and recommended him to wealthy employers. Let one instance of many suffice. Henry Earl of Clarendon, writing to Evelyn in 1686, thanks him "for speaking to Mr. London to go to Swallowfield." This was the Earl's estate near Reading, the gardens of which had been much neglected.

Sir Christopher Wren also employed London relative to the gardens to be formed about mansions of which he was the architect. Evelyn employed them both, as he thus tells—"June 9. 1698. I went to Deptford to see how miserably the Czar (Peter of Russia) had left my house after three months making it his court. I got Sir C. Wren, the King's Surveyor, and Mr. London, his gardener, to go and estimate the repairs, for which they allowed £150 in their report to the Lords of the Treasury." The ravages in the garden may be estimated from the fact that one of the amusements of the Czar was to sit in a wheelbarrow whilst one of his court drove it through the high Box-edgings.

Immediately that William and Mary were established on the throne, Mr. London was appointed Superintendent of all the Royal Gardens with an annual salary of £200; and to this appointment was added that of page of the back-stairs to the Queen, and when Anne succeeded to the throne he was continued in his offices. It is not difficult to discern that other circumstances sustained him in preferment in addition to his great merits as a skilled horticulturist. We have already stated that he was the Bishop of London's head gardener, and the Bishop knowing him to be a sincere Protestant, and discerning, as did Mr. Rose, his promptitude and vigour, selected him as a coadjutor in securing the safety of Princess Anne. Attempts

had been made to induce her to become a Roman Catholic. It was known she doubted the legitimacy of her alleged half-brother. Her husband, Prince George of Denmark, had fled from her father, James II., and the latter was hastening to London breathing vengeance against her favourites the Churchills. The sentinels about her residence were doubled, so at the midnight of a day in the November of 1688 she fled from the palace. She went first to the Bishop, Mr. London's master, and on the following morning left the metropolis for Epping Forest, and went thence to Northampton and on to Nottingham. The Bishop, says Macaulay, wholly laid aside, for the time, his sacerdotal character. Danger and conflict had rekindled in him all the military ardour which he had felt twenty-eight years before, when he rode in the Life Guards. He preceded the Princess's carriage in a buff coat and jackboots, with a sword at his side and pistols in his holsters. It was particularly observed, says Switzer, that Mr. London assisted on that occasion. The same contemporary adds—

"Mr. London and Mr. Wise being joint-partners, and thus as it were, both possess'd of the royal favour, and the purses of the King, Queen, and nobility, left no stone unturn'd to carry on their designs. Soon after the peace of Ryswick [1697], Mr. London took another journey into France with the Right Honourable the Earl of Portland, who was sent by King William Ambassador-extraordinary on that occasion; and then it was that he made those observations on the fruit gardens at Versailles, which are publish'd in the preface to their abridgement.

"After the death of the Queen [Mary], and not many years after her, the King [William], their royal successor Queen Anne committed the care of her gardens in chief to Mr. Wise, Mr. London still pursuing his business in the country. It will perhaps be hardly believed, in time to come, that this one person actually saw and gave directions, once or twice a-year, in most of the noblemens and gentlemens gardens in England. And since it was common for him to ride fifty or sixty miles in a day, he made his northern circuit in five or six weeks, and sometimes less; and his western in as little time. As for the south and east, they were but three or four days work for him; most times twice a-year visiting all the country seats, conversing with gentlemen, and forwarding the business of gard'ning in such a degree as is almost impossible to describe. In the mean time, his collegue manag'd matters nearer home with a dexterity and care equal to his character: And in truth, they have deserv'd so much of the world, that 'tis but common justice to transmit their memory unto ages to come.

"But to speak more particularly of the knowledge Mr. London was suppos'd to be master of in this matter, the little opportunity he had in laying a foundation of learning, was, without doubt, a great obstruction to his progress in vegetative philosophy, which is involv'd in so many hard terms; this, nevertheless, he overcame purely by industry; and what he wanted in one, he abounded with in the other. He was perfectly well skilled in fruit, which seem'd to be his master-piece: As for other parts, as greens, trees, flowers, exoticks, and the like, he certainly had as much knowledge as any one man living: And tho' he might not always come up to the highest pitch of design, yet that might be attributed to the haste he was generally in; and it can be no great blemish to his character, that he was not the greatest person in every thing, when 'tis surprizing to find he could possibly know so much; so great a surprize indeed, that we must hardly ever expect his equal, much less any one that will exceed him. The planting and raising of all sorts of trees, is so much due to his undertaking, that 'twill be hard for any of posterity to lay their hands on a tree, in any of these kingdoms, that have not been a part of their care.

"Mr. London, by his great fatignes in heat and cold, notwithstanding naturally of a healthy, strong constitution, was at last seiz'd with an illness which carry'd him off, after a few months languishing. He has left a laudable example to all that shall have the encouragement to enter, and the courage and strength to perform what he did. He died towards Christmas, in the year 1713."

In every instance that we have had to dwell over the career of a praiseworthy public servant we have wished to penetrate within the front door of his residence, and to learn more of his fireside doings; we have been thus inquisitive about Mr. London, but with small success. We have already noticed that his services had been rewarded by a Court appointment, and we found in the Fulham register that when buried on the 15th of January, 1714, he was entitled "George London, Esq." The introductory sentence of his will, dated December the 2nd of the previous year, also designates him "of St. Martin's-in-the-Fields, Gentleman." He had, therefore, a residence near St. James's Palace, rendered necessary, probably, by his office of page. It is described in his will as the "house where he then dwelt, which, with the garden and appurtenances, were taken out of the Woodworks near Spring Gardens." That house and grounds cost Mr. London, according to particulars we have, £267 14*s.* 8*d.* He had to purchase the right of possession from "Esqe. Povey," who was the previous grantee from the Crown. At that time some part of the ground was farmed, and we can hardly realise that for a purchase of ground in Spring Gardens £5 "had to be paid for the Corne upon ye Land." The purchase was completed in the April of 1693, for Mr. London's book-keeper then entered, "Paid at the reaconing at the Crowne Taverne, at Charing Cross, at the meeting about sealing the lease for the new house, 01—00—00."

Mr. London directed that he should be buried in the parish church of Fulham, "near the body of his first dear wife Rebecca," adding the dictate of common sense, "the funeral expenses not to exceed forty pounds." There, as he wished, his body rests, and in the same grave with his second wife, Elizabeth, who died in 1732, and on the slab in the aisle is recorded that she was "widow of Mr. George London, who is here interred."

He had acquired considerable property, for he had lands at Kingston and Long Ditton, shares in the Welsh lead mines, called St. Carbury, which he devised to his eldest son George. His share in the Brompton Park Nursery he bequeathed in trust for his youngest son John. He had three daughters, all married to members of the upper ten thousand. Katherine was become Mrs. Elford; Rebecca, dead at the time of the will being executed, had been Mrs. Woodward; and Henrietta was the wife of Sir John Peachey, and their second son was created Earl Selsey. Henrietta, we can testify, was a skilful artist. Her father bequeathed to her his "fine book of Surinam plants in colours, to which are annexed her drawings of plants in colours, pourtraying forty plants from the Cape of Good Hope, and several fruits in colours, bound in rough leather, they being all drawn by her." Some of her drawings we have seen in the library at Badminton. There are many money legacies to grandchildren and cousins, an annuity to his widow, and the use of his "silver tea-kettle stand" and other plate, all testifying that he had won his way well up in the ranks of society.

To the poor of Fulham he left £5. Was it his birthplace? or was the gift born of that turning of the heart which all must feel towards the place of their early happiness and prosperity? We know that at Fulham he was the long-trusted gardener of Bishop Compton, that there he married his first wife, and that the union was happy is told that there he wished to rest finally by her side.

Before we withdraw our pen from this subject, we must record the pleasure we derived from the depositary where we found Mr. London's will. That depositary is Doctors' Commons. Thither we resorted with no vagrant intent, but were received with such courtesy by J. F. Coleman, Esq., one of the keepers of the records, and he so genially led the way through the marvellously well-arranged store halls, that we gladly diverged from the immediate object of our research. To preserve the records from destruction by fire, no wood forms any part of the building or its fittings—rafters, floorings, staircases, shelves are all of iron or thick glass. The wills are chronologically arranged—the months of each year being in labelled packets, so that the date being known, any will is promptly found, and of the wills of modern date even an alphabetical index to the testaters' names is printed.

Our kindly guide placed before us the will of "William Shakespere"—for that is his own spelling of his very legible autograph. The will is on three sheets of writing paper, each sheet between two panes of glass, and framed, to preserve them from the fingers of the thoughtless "Man of Feeling." Then we looked upon the will of William Pitt, short and unconnected, evidence that though a worthy foeman of Fox in debate, he was not his equal in literary composition. Next was shown the will of "Nelson and Bronte," written in large characters with the left hand, as shown by their leaning inversely, written, too, in a small book red-leather-covered, such as tradesmen send to customers detailing the week's account. Lastly, we saw the will of "Wellington," unmistakeable both in its caligraphy and straightforwardness. Of the earliest wills there are very many volumes of copies on parchment, some brilliantly illuminated, and others, especially one dated 1581, the most beautiful—perfectly uniformly beautiful—examples of penmanship we ever perused.

Nor were the concluding minutes of our visit the least gratifying, for our tender of thanks was met by the response, "No, I'm in your debt, for you have led me to, and instructed me in, gardening."

Potatoes in Great Britain and Ireland.—The number of acres in Great Britain planted in 1869 were 585,211, and in 1870

587,661. In Ireland in 1869 there were so planted 1,041,837 acres; and in 1870 there were 1,043,788 acres.

ROYAL HORTICULTURAL SOCIETY.

MARCH 15TH.

SPRING SHOW.

A CHILLY north-west wind and large flakes of snow, which melted as they fell, gave early in the day but a poor prospect of an enjoyable Show even if held, as that Show was, in the Conservatory. Still, unfavourable as the morning was, it was not so much so as one which some can remember, who in that same Conservatory had "to dodge" the falling squares of glass, broken by the weight of the sliding snow, and there was room to hope for better things; nor was hope disappointed, for as the day advanced the sun broke forth and gave the wished-for warmth and life. Mr. Eyles, however, had provided against all contingencies, and whilst securing the Conservatory for warmth, he had an awning which at once protected the flowers from the sun and showed them off to advantage. As regards the quality of the exhibition, horticulturally speaking, it was fully equal to that of last year, and nowhere was any falling-off visible. The Hyacinths and the Tulips were simply magnificent, and it must be noted that the largest portion of the display, both of these and miscellaneous subjects, came from exhibitors showing in a way in which they could derive from the Society no prizes which could nearly compensate them for their trouble and expense. This speaks well for the good feeling which exists towards the Society, and the general wish to promote the success of its objects. The attendance of visitors was most satisfactory.

Class 1 was for eighteen Hyacinths, distinct sorts. In this Messrs. Veitch were first with splendid massive examples of the following—viz., *Single Red*, Vanrbank, fiery crimson, very brilliant and effective; Macaulay, Garibaldi, remarkably fine. *Double Red*, Koh-i-Noor. *Mauve*, Haydn, very fine. *Single Blue*, King of the Blues, very fine; La Grande Resemblance, Charles Dickens, Blondin, Grand Lilas; General Havelock and Feruck Khan, of the black shades. *Double Blue*, Laurens Koster. *Yellow*, Ida. *Single White*, La Grandesse, magnificent; Alba Maxima, L'Innocence, and Leviathan, very fine. Messrs. Cutbush were second, also with a splendid collection, but with some of the varieties not equal to those in the first-prize collection. Messrs. Cutbush's collection consisted of—*Single Red*, Von Schiller, very fine; Florence Nightingale, Princess Clothilde, Macaulay, a grand spike; Giganteu. *Double Red*, Duke of Wellington, fine. *Single Blue*, Lord Palmerston, fine; Charles Dickens, Czar Peter, fine; Argus, Baron Von Tuyll, Marie, fine; and General Havelock and Feruck Khan of the black shades. *Single Yellow*, Ida. *Single White*, Mirandoline, Queen of the Netherlands, and Grandeur à Merveille.

Class 2 was for eighteen White Hyacinths. In this Messrs. Veitch were again first with a remarkably fine collection, consisting of Madame Van der Hoop, with large white bells, very broad in the segments; La Grandesse, equally fine, and with a larger spike; Baroness de Vander Duin, Grand Vainqueur, Orondates, Snowball, fine; Leviathan, a very fine blush; Queen of the Netherlands, Paix de l'Europe, Madame de Stael, Alba Superbissima, La Candeur, Mont Blanc, Grandeur à Merveille, Lord Shaftesbury, with bells of remarkable size; L'Innocence, Alba Maxima, and Prince of Waterloo, double. Messrs. Cutbush were second with several of the above kinds; Tubiflora, Voltaire, and Maria Cornelia of the blush shades; Princess Helena, Victoria Regina, &c.
